PARTIAL LIST OF CONTRIBUTORS TO VOLUME XV

ALESSIO, GUILIO (Hon.)
Member of Parliament; Formerly Secretary of State for the Treasury; Professor of Finance, Royal University of Padua.

ITALY — ITALIAN FINANCE

ANESAKI, MASAHARU
Professor of the Science of Religion, Imperial University, Tokio

JAPAN — THE RELIGIONS OF JAPAN

ARCOLEO, GIORGIO
Professor in Ordinary of Constitutional Law, of Comparative Public Law, Royal University of Naples; Grand Official of the Italian Crown; ex-Deputy in Parliament for Six Legislatures; Senator of the Kingdom.

ITALY — CROWN AND PARLIAMENT

BABASINIAN, V. S.
Professor of Chemistry, Lehigh University

IODOFORM

BOGART, ERNEST L., Ph.D.
Professor of Economics, University of Illinois

INDUSTRIAL REVOLUTION

BRIGHAM, JOHNSON
Librarian, Iowa State Library, Des Moines

IOWA

BROWN, CHARLES RUFUS
Professor of Hebrew and Cognate Languages, The Newton Theological Institution, Newton, Mass.

ISAIAH
ISAIAH, BOOK OF

BUCKINGHAM, EARLE
Associate Member, American Society Mechanical Engineers

INTERCHANGEABLE PARTS

BUELL, MARCUS D., S.T.B., D.D.
Professor of New Testament Greek and Exegesis, Boston University School of Theology

JAMES, EPISTLE OF

CALLAHAN, JAMES M., Ph.D.
Professor of History and Political Science, West Virginia University

ITALY — DIPLOMATIC RELATIONS OF THE UNITED STATES WITH
JAPAN — DIPLOMATIC RELATIONS OF THE UNITED STATES WITH

CAMMEO, FEDERICO
Professor of Jurisprudence, Royal University of Padua

ITALY — COMMUNAL AND PROVINCIAL ADMINISTRATION

CANDIANA, COUNT
Admiral of the Royal Italian Navy

ITALY — THE NAVAL MARINE

CASCIANI, PAOLO (Hon.)
Member of Parliament; Commendatore della Corona d'Italia; Professor of Agronomy, Royal University of Rome

ITALY — AGRICULTURE IN ITALY

CHAMBERLAIN, ALEX. F.
Late Professor of Anthropology, Clark University.

LEONARD-STUART, CHARLES
Editorial Staff, The Americana

INDIANS, AMERICAN

CHIAPPELLI, ALESSANDRO
Professor of Philosophy, Royal University of Naples; Commendatore della Corona d'Italia; Author of "The Philosophy of Religion," etc.

ITALY — RELIGION IN ITALY

CORDARA, CARLO
Musical Critic of "Marzocco;" author of "La Tentazione di Gesin," etc.

ITALY — ITALIAN MUSIC

COUMBE, CLEMENT W.
Technical Art Expert

IVORIES
JAPANESE CERAMICS
JAPANESE AND ORIENTAL ARMS AND ARMOR

CROSS, WILBUR L., Ph.D.
Professor of English, Yale University

JANE EYRE

DARTON, NELSON H.
United States Geological Survey

INLAND WATERWAYS

DESSAU, B.
Professor of Physics in the University of Perugia

ITALY — NATURAL AND PHYSICAL SCIENCES IN ITALY

DOMINICIS, SAVERIO DE
Professor of Pedagogy, Royal University of Pavia; author of Works on Teaching in Schools and Universities

ITALY — EDUCATION IN ITALY

DRUM, WALTER, S.J., A.B.
Late Professor of Scripture, Woodstock College

JANSENISM

DUNN, JACOB PIATT
Secretary Indiana Historical Society

INDIANA

DUNN, JOSEPH, Ph.D.
Professor of Celtic Languages and Literatures, The Catholic University of America
IRISH SCHOOLS AND SCHOOLMEN OF THE MIDDLE AGES

FALLETTI, PIO CARLO
Professor of Modern History, Royal University of Bologna
ITALY — THE RENAISSANCE IN ITALY

FARROW, EDWARD S., C.E.
Consulting Military and Civil Engineer
INFANTRY

FAY, EDWIN WHITFIELD, Ph.D.
Professor of Latin, University of Texas
INSCRIPTIONS

FERRIS, RICHARD, C.E., D.Sc.
Editorial Staff of The Americana
INDIA RUBBER

FISKE, HALEY, A.M.
President of the Metropolitan Life Insurance Company
INSURANCE, INDUSTRIAL

FITZPATRICK, BENEDICT
New York City
IRISH ARCHÆOLOGICAL REMAINS

FORTUNE, WILLIAM
President Indianapolis Chamber of Commerce
INDIANAPOLIS, IND.

GARNER, JAMES W., Ph.D.
Professor of Political Science, University of Illinois
INTERNATIONAL LAW, CHANGES IN

GAUSS, CHRISTIAN, Litt.D.
Professor of Modern Languages, Princeton University
JEAN CHRISTOPHE

GRAZIANI, AUGUSTO
Professor of Political Economy, Royal University of Naples; Honorary Professor, University of Siena
ITALY — ECONOMIC CONDITIONS IN

GREINER, A. F., M.E.
Assistant Professor of Mechanical Engineering, University of Michigan.
INTERNAL COMBUSTION ENGINE

GRIFFIS, WILLIAM ELLIOT
Author of "The Mikado's Empire" and "America in the East."
JAPAN — HISTORY OF JAPAN, 1889–1919
JAPAN — JAPANESE LANGUAGE, THE
JAPAN — JAPAN IN THE WORLD WAR
JAPANESE STUDENTS IN AMERICA
JAPANESE WAIFS IN AMERICA

HALLER, WILLIAM, Ph.D.
Instructor of English, Columbia University
IRISH MELODIES

HAMLIN, A. D. F., A.M., L.H.D.
Professor of the History of Architecture, Columbia University
INTERIOR DECORATION

HANFORD, JAMES H., A.M., L.H.D.
Associate Professor of English, University of North Carolina
ISABELLA
IVANHOE

HAUSMANN, PHILIP W.
Albany, N. Y.
IRREDENTISTS

HAYFORD, JOHN F., C.E.
Director College of Engineering, Northwestern University
ISOSTASY

HOFFMAN, FREDERICK L., LL.D.
Statistician of the Prudential Insurance Company of America
INSURANCE, SCIENCE AND ECONOMICS OF

HUNT, LEIGH
Professor of Art in The College of the City of New York
ITALY — ITALIAN ART IN THE 19th AND 20th CENTURIES

HUTCHINSON, J. I., Ph.D.
Professor of Mathematics, Cornell University
INTEGRAL EQUATIONS

IHLDER, JOHN
Executive Secretary, Philadelphia Housing Association
INDUSTRIAL HOUSING IN THE UNITED STATES

ISAACS, LEWIS M., Ph.B., LL.B.
Musical Critic and Composer
INQUISITIVE WOMEN

JERNEGAN, MARCUS W., Ph.D.
Associate Professor of History, University of Chicago
INTERNATIONAL CLAIMS AND DISPUTES
JACKSON, ANDREW

JOHANNIS, ARTURO JEHAN DE
Director of the Royal Institute of Social Science, Cesare Alfieri, Florence
ITALY — ITALIAN INTERNATIONAL COMMERCE

Contributors to Volume XV—Continued

JONES, EDWARD D., B.S., Ph.D.
Professor of Business Administration, University of Michigan; author of "Administration of Industrial Enterprises," etc.
INDUSTRIAL DISTRIBUTION
INDUSTRIAL ORGANIZATION AND ADMINISTRATION

KANEKO, KENTARO, VISCOUNT, LL.D.
Privy Councillor, Tokio
JAPAN — THE JAPANESE CONSTITUTION

KAINS, M. G., B.S., B.S.A., M.S.A.
Horticultural Consultant
INSECTICIDE
INSECTS OF IMPORTANCE TO MAN

KASNER, EDWARD, Ph.D.
Professor of Mathematics, Columbia University
INVARIANTS AND COVARIANTS

KENNARD, JOSEPH S. Ph.D., D.C.L., LL.D.
Author of "Italian Romance Writers," etc.
ITALY — ITALIAN SOCIALISM
ITALY — ITALIAN LITERATURE

KEYSER, CASSIUS J., Ph.D.
Adrain Professor of Mathematics, Columbia University
INDUCTION, MATHEMATICAL

KLEIN, HENRI F.
Editorial Staff of The Americana.
IRELAND
IRISH REBELLION
ITALY AND THE WORLD WAR

KUKI, BARON RYUICHI
Privy Councillor and Custodian of the Imperial Art Treasures
JAPAN — HISTORY OF JAPANESE FINE ART

LADD, GEORGE TRUMBULL, LL.D.*
Emeritus Professor of Metaphysics and Moral Philosophy, Yale University; Lecturer on Education in the universities of Japan
JAPAN — MENTAL CHARACTERISTICS OF THE JAPANESE

LA FÉTRA, LINNÆUS EDFORD, M.D.
Associate in Diseases of Children, Columbia University; Director of Children's Medical Division, Bellevue Hospital
INFANCY

LENNOX, P. J., B.A., Litt.D.
Professor of English Language and Literature, The Catholic University of America
IRISH LITERARY REVIVAL
IRISH LITERATURE IN ENGLISH

THE ENCYCLOPEDIA AMERICANA

I

INDIA, also called **HINDUSTAN** or **INDOSTAN,** derived from the Persian form of the Sanskrit *sindhu,* a river, and signifying "the land beyond the Indus," is a name used both in ancient and modern times with great latitude of signification. The mainland of India proper is bounded north by the main range of the Himalaya Mountains; east by mountain ranges which divide it from Burma; southeast by the Bay of Bengal; south by the Gulf of Manaar, which separates it from Ceylon; west by the mountain chains enclosing the valley of the Indus, which separates it from Afghanistan and Baluchistan, and by the Indian Ocean. Its length north to south is nearly 2,000 miles; its greatest breadth east to west about 1,800 miles. It extends between lat. 8° 5′ and 35° 15′ N., and long. 65° 45′ and 97° E.

Political Divisions.— Legally "British India" means all territory governed by the "King-Emperor" or "Kaisar-i-Hind," as the monarch of Great Britain is designated in Hindustan together with any territories of native princes or rulers under the suzerainty of the king of England exercised through the governor-general and viceroy of India.

In 1912 administrative changes resulted in the division of British India into 15 provinces as follows:

BRITISH PROVINCES	Area in square miles (1921)	Population in 1921
Ajmer-Merwara	2,711	495,271
Andamans and Nicobars	3,143	27,086
Assam	53,015	7,606,230
Baluchistan	54,228	420,648
Bengal	78,699	46,695,536
Bihar and Orissa	83,181	34,002,189
Bihar	42,361	23,380,288
Orissa	13,743	4,968,873
Chota Hagpur	27,077	5,653,028
Bombay (Presidency)	123,059	19,348,219
Bombay	75,993	16,012,342
Sind	46,986	3,279,377
Aden	80	56,500
Burma	230,839	13,212,192
Central Provinces and Berar	99,823	13,912,760
Central Provinces	82,057	10,837,444
Berar	17,766	3,075,316
Coorg	1,582	163,838
Madras	142,330	42,318,985
North-West Frontier Province*	13,418	2,251,340
Punjab	99,222	20,685,024
United Provinces	107,267	45,375,787
Agra	83,109	33,209,145
Oudh	24,158	12,166,642
Total provinces	1,093,074	247,003,293

* Districts and Administered Territories.

Delhi, 557 square miles, Pop. 488,188, a small enclave in the Punjab. was constituted a province and a separate territory under a chief commissioner 1 Oct. 1912, and became the capital of the empire and the seat of government, removed there from Calcutta.

The *Native States* with numerous tribal subdivisions, ruled by native princes who are feudatory to British authority and responsible to the viceroy of India for their good government, are as follows:

STATE OR AGENCY	Area in square miles	Population, 1921
Assam State (Manipur)	8,456	384,016
Baluchistan States	80,410	378,977
Baroda State	8,182	2,126,522
Bengal States	5,393	896,926
Bihar and Orissa States	28,648	3,959,669
Bombay States	63,864	7,409,429
Central India Agency	52,260	5,997,023
Central Provinces States	31,174	2,066,900
Gwailor State	25,107	3,186,075
Hyderabad State	82,698	12,471,770
Kashmir State	84,432	3,320,518
Madras States	10,549	5,460,312
Cochin	1,361	979,080
Travancore	7,594	4,006,062
Mysore State	29,475	5,978,892
N. W. Frontier Province (agencies and Tribal areas)	25,472	2,825,136
Punjab States	36,551	4,416,036
Rajputana	128,987	9,844,384
Sikkim State	2,818	81,721
United Provinces States	5,079	1,134,881
Total Native States	709,555	71,939,187
Total India	1,802,629	318,942,480

Physical Features.— The natural boundaries of the peninsula of India, which forms a triangle washed on two sides by the sea and having its base in the great mountain chain which separates it from Tibet on the north, are completed by its three great rivers, the Indus, the Ganges and the Brahmaputra. These all rise in the Tibetan Mountains beyond the Himalayas, and the first flowing west, the two latter east, descend in a southern direction toward the sea; the Indus discharging itself into the Indian Ocean; the Ganges and the Brahmaputra, after watering in their separate courses a large part of northern India, uniting to pour their waters together by numerous mouths into the Bay of Bengal. The mountains enclosing the basins of these rivers form the east and west boundaries of the northern part of the peninsula. The Himalayas, the loftiest mountain range in the world, with heights of upward of five miles above the level of the sea, descend by successive slopes to the elevated plain of northern India. (See INDUS; GANGES; BRAHMAPUTRA; HIMALAYA). The entire peninsula is sometimes distinguished by three natural divi-

sions. The Vindhya Mountains, a range of about 3,000 feet in height, which extends irregularly across the peninsula from Gujarat to the basin of the Ganges, forms an anciently-recognized division into two parts under the names of Hindustan and the Deccan (Southern Land). The name Hindustan, given in this restricted sense to the northern part of the peninsula, is frequently applied to the whole. The ancient division of the Deccan is again subdivided into two, the name Deccan being restricted to the northern part, the southern from the river Krishna or Kistnah, which flows from west to east almost across the whole peninsula, being called southern India or India south of the Krishna. The portion of India watered by the Ganges and its tributaries is by far the most fertile and populous of the whole. At no great distance from the opposite extremities of the Vindhya Mountains two great ranges proceed southward along the line of the coast. The Western Ghâts, which attain a height of 5,000 to 6,000 feet, though at some parts much lower, proceed along the west coast to Cape Comorin, the southernmost point of India. They do not generally recede more than 40 miles from the sea, and rarely more than 70. On the sea side their descent is generally precipitous, forming a regular sea-wall. On the land side they descend gradually, and sometimes almost imperceptibly, to the elevated plains of the interior. The Eastern Ghâts recede farther from the east coast, are less elevated and precipitous. Before reaching as far in their southern course as Madras, they trend inward and unite with the transverse range of the Nilgiri Hills, which connects them with the Western Ghâts. This mountain-formed triangle encloses an elevated table-land with a gradual slope eastward from the Western Ghâts, and which is continued beyond the Eastern Ghâts to the sea. The elevation of the plain of southern India also increases toward the south. In the Deccan it is about 3,000 feet above the level of the sea. In the neighborhood of the Nilgiri Hills, which rise 3,000 feet above it, it reaches 7,000 feet.

Hydrography.— The chief rivers of India besides the Indus, Ganges and Brahmaputra, already named, are the Jamna, Ramganga, Gumti, Gogra, Gandak, Kusi, etc., tributaries of the Ganges; the five rivers of the Punjab, Satlej, Bias, Ravi, Chenab and Jhilam, tributaries of the Indus; the Nerbudda, enclosed on its northern bank by the Vindhya Mountains and the Tapti, which flow west into the Gulf of Cambay, the Mahânadi, the Godâvari, the Kistna, North and South Pennar, Vellar, Kaveri, etc., all flowing eastward into the Bay of Bengal. The uniform direction of the great rivers south of the Tapti is explained by the inclination of the land already described. The coasts of India have very few indentations and consequently very few good natural harbors. The western coast is known by the name of the Malabar, the eastern by that of the Coromandel coast. There are no lakes of any extent in India — Chilka and Kolair near the east coast being the largest.

Geology.—All the great mountain ranges are chiefly composed of granite and of granitic rocks, which form also the base of the plateau of the Deccan. Both in the peninsula and in the Himalayas gneiss predominates, associated with micaschist, hornblende-schist, chlorite slate and primitive limestone. Syenite prevails in the southeast of the peninsula. In the southern portion of the Western Ghâts the granitic rocks are overlaid by an iron clay, which is continuous to the end of the peninsula, and reappears in the island of Ceylon. In the upper portion of the Western Ghâts and adjoining ramifications of the Vindhya Range, basaltic trap in various forms overlies the granite to an extent unparalleled elsewhere in the world. It entirely covers a large portion of the table-land of the Deccan. In this district, trap and granite frequently pierce the surface in isolated masses, forming flat-topped hills nearly perpendicular, and which can only be ascended by steps, or winding, dangerous paths. These have been converted into strongholds from a remote antiquity. They are frequently crowned with forts and form a peculiar feature of the landscape. On the lower sides of the Himalayas regular strata of the Secondary and Tertiary periods are largely developed. Many of the sandstones and shales of the Secondary period belong to the coal-measures. The Indian Tertiary formations attain their greatest breadth toward Sind and the Punjab, where fossil remains, including many of singular forms and gigantic dimensions, are abundant.

Mineral Resources.— The principal coal fields in India are found in the region bounded north by the Ganges, south by the Godâvari, and stretching east and west from the neighborhood of Calcutta to the middle of the valley of the Narbada. Indian coal is distinguished by its excessive lamination. The annual production in India was 22,628,037 tons in 1919, from 427 collieries worked throughout Bengal Hyderabad, Assam, Rewah, the Central Provinces, Punjab, Baluchistan and Burma. The most important mines are those of the East Indian Railway Company near Giridhi (Bengal) and the Singareni mine in Hyderabad. Of the coal used on the railways 95 per cent is Indian coal. Iron ore is abundant in many parts of India, but the amount produced is still small. The only large iron-works in India are at Sanchi and Barrakur in Bengal, but iron is manufactured locally on a small scale in other parts of Bengal and in the central provinces. The chief obstacle to the successful development of the iron industry of India is the difficulty of finding the ore, fuel and flux sufficiently near to one another to make it profitable, but it is believed that iron-works near Calcutta, using Madras ore and Bengal coal, would succeed. The Tater Ironworks at Sanchi, lately started, is the largest in Asia. Gold is worked to some extent, more especially in Mysore, the total production in 1919 being 507,261 ounces. Copper, lead, antimony and other metals are fairly abundant. Burma yields a large amount of petroleum annually, and smaller quantities are obtained from Assam and the Punjab. The total output of 1919 was valued at about £1,834,-308, but much is still imported. There are valuable ruby mines in Upper Burma, and a few diamonds are still obtained in Central India. Salt is an important manufacture and source of revenue; its production is treated under the head of *Finance*.

Soils.— The alluvial deposits along the mountain valleys and in the plains, and the soil composed of disintegrated rock masses on the plateaus, are especially rich and of great productivity. Their fertility is greatly enhanced

Strait of Malacca

and maintained by an elaborate system of irrigation. See paragraph in this article on *Canals and Irrigation*.

Climate. – India extends 15½ degrees within north tropical latitudes, and 12½° within the temperate zone. Owing to modifying circumstances, the climates contained within this range are not only extremely various, but distributed with great irregularity. One of the chief modifying circumstances is the distribution of moisture, the great regulators of which are the monsoons. The northeast monsoon blows from October to March, the southwest from April to September. The latter surcharged with vapor from the Indian Ocean condenses in torrents on the heights of the western Ghâts, and forms the rivers which flow to the east. Before it reaches the Coromandel coast in the southeast it becomes a dry wind which scorches up vegetation. In the west, on the contrary, this wind passes over the low plains in the lower valley of the Indus, is arrested by the Himalayas, and fills the tributaries of the Ganges. The northeast monsoon runs a similar course in the opposite direction, but deriving less moisture from the Bay of Bengal, which is of less extent than the Indian Ocean, it has less influence on the climate, and its season is in general the dry one. The great plain of Southern India being exposed to greater heat than that of Northern India, and not being watered by the snow-fed streams of the Himalayas, is naturally much less fertile. The seasons in India are divided into rainy, cool and hot. The periods of these different seasons vary according to latitude and modifying circumstances. On the Malabar coast the rain begins earliest to the south. At Calcutta rain falls from June to October; the cool season begins about November, the hot season in February, the heat increasing gradually till May. In Calcutta where the mean annual temperature is about 79°, the range is from 50° to 85° F. In Bombay the mean annual temperature is about 82°, the range about 10°; in Madras mean about 84°, range 7° to 8°. The annual rainfall in India is much greater than that of England; but it is distributed with great irregularity. The basin of the Indus, including all Sind and the half of the Punjab, is an arid region with an annual rainfall under 15 inches. The high plateau in the interior of South India has an annual rainfall generally under 30 inches. On the whole Malabar coast the rainfall is over 75 inches; at Kananor it reaches 128 inches. On the Coromandel coast it is very much lower, being 45 inches at Vizagapatam, 50 inches at Madras, while farther south it falls below 30 inches. Between the arid region of the Indus and the Ganges runs a dry zone of 100 to 200 miles wide, including Lahore, Delhi and Agra, with a rainfall between 15 and 30 inches. The valleys of the Tapti, the Nerbudda, the lower part of the Jamna, the Ganges and the Brahmaputra, are generally over 30. Along the slopes of the Himalayas from Cashmere east to the boundaries of India, and southeast to the mouths of the Mahánadi runs a belt of country with a rainfall over 60 inches, within which is included the lower course of the Ganges. Within this is another belt, including a lower slope of the Himalayas, and the lower course of the Brahmaputra before its junction with the Ganges, in which the rainfall rises above 75 inches.

Forests.— The three most valuable timber trees of India are the teak (*Tectona grandis*), the sâl or saul (*Shorea robusta*), and the deodar (*Cedrus Deodara*). The teak grows most luxuriantly along the Bombay coast, in Travancore and Cochin and in Burma, but it is also abundant throughout much of Central India and elsewhere. The sâl is the chief forest tree of the Himalayan slopes, from the Satlej eastward to Assam, and it grows also in the forests of Central India and the Eastern Ghâts. The home of the deodar is the northwestern Himalayas. Among the most valuable trees of the densely forested Western Ghâts from Kanara to Travancore and Mysore are teak, blackwood, bamboos, sandal-wood, a kind of ebony and *Calophyllum inophyllum*, whose wood is prized for the spars of ships. In the United Provinces and neighboring districts the leading species are sâl and several varieties of pines, and in the extensive jungles of the Ganges delta the most useful wood is that of the sundari (*Heretiera littoralis*). The forests of Assam yield sâl, *Pinus Kasya*, caoutchouc (*Ficus elastica*), and other useful species and plantations of teak, tun or toon (*Cedrela toona*), and sissoo (*Dalbergia sissoo*) have been laid out. Besides teak the Burmese forests contain ironwood and the cutch-tree (catechu). Before the formation of the Indian Forest Department the forests were recklessly destroyed by timber-cutters, nomadic cultivators and others, but large forest areas in all the provinces have now been marked off as reserved forests under the immediate care of the forest officers, and other forest areas have been brought under partial conservancy. Timber-cutting and grazing have been either prohibited or restricted; and plantations of the more useful trees have been formed in many parts of the country. In every province a few of the most valuable timber trees are declared to be reserved trees, and can only be felled under special license. Forest revenue is raised by royalities on, or by the sale of, timber or other produce, and by the issue at specified fees of permits to graze cattle, or to extract for sale timber, firewood, charcoal, bamboos, canes, and other minor forest produce. The reserved forests now cover an area of more than 96,867 square miles, and the protected or partially conserved forests occupy other 142,000 square miles. Some of the native states, such as Mysore, Travancore, Baroda and Kashmir, have followed the example of the British government.

Flora.— Where moisture is plentiful, as in the valley of the Ganges, vegetation is superabundant. The delta of the Ganges, in particular, called the Sunderbunds, is covered with dense jungle full of the largest wild animals, and the excessive vegetation renders most of the mouths unnavigable. There are many other similar tracts of extensive forest and jungle. On the Coromandel coast, where the heat which reaches 100° F., vegetation is not luxurious, and the delta of the Indus from the southeast of the Punjab to the Ran, or great salt marsh of Kach (Cutch), forms a great sandy desert, continuous across the river with the desert of Baluchistan, and with a wide band stretching across the whole continent of Asia to Central Africa. In the various altitudes of the Himalayas forms of vegetable and animal life belonging to all the various climates from tropical to polar are to be found. These as well as

the Western Ghâts are magnificently wooded. Orchids, rhododendrons and other valuable flowers are common. Among the staple natural products of India are rice, maize, wheat, barley, cotton, flax, hemp, jute, rhea, indigo, tea, coffee, sugar-cane, opium, tobacco, ginger, pepper cardamoms, palms bearing nuts which are extensively consumed, anise, dye-woods, etc. European fruits abound, and among indigenous fruits may be mentioned the mango, plantain, pomegranate, citron, date, almond, grape, guava, pineapple and tamarind. Palms, including the date, cocoanut, palmyra, betel-nut and other species, the banyan, and bamboo, are common features of the vegetation.

Fauna.— The elephant, the rhinoceros, the camel, the tiger, a few lions in the northwest, the leopard, bears, hyena, jackal, wolf and numerous smaller carnivora, the boar, antelopes, deer, wild ox, ass, sheep and goat, monkeys in great variety, and the greater number of European quadrupeds are found. There are several large species of ox, such as the gaur or "bison" and the arnee or wild buffalo. Crocodiles, snakes (including the dreaded cobra), and reptiles in all varieties are very numerous; of birds, the eagle, vulture, falcons, peacock, parrots, king-fishers, mina-bird, partridge, quail, heron, stork, are characteristic species, and other varieties, both indigenous and common to other regions, are numerous. Fish are plentiful and in great variety, both on the coasts and in the rivers.

Land Tenure and Revenue.— In India the state, or the monarch, has always enjoyed a share in the rent or profits from the land. Before the advent of the Mohammedans and the establishment of the Mogul Empire the almost universal unit for the purposes of revenue collection was the village community. In a village, community land was held, not by private owners, but by cultivators occupying it under the village corporation, and the land revenue was collected from the head-man as representing the community. With the Mohammedan conquest new methods of revenue collection were introduced. The state claimed one-sixth of the gross produce of the soil as its share, and entrusted its collection to persons who each agreed to pay a definite amount from the district assigned to him. These revenue farmers, known as *zamindars*, were often local magnates under the old Hindu system.

The term "settlement" is applied in Indian revenue affairs to the process of assessing the land revenue demand. Occasionally, in newly acquired or specially backward tracts, the land revenue is assessed for a short term of years on a general review of the circumstances and capabilities of the land and people concerned; such a process is called a summary settlement. But a regular settlement is a more complicated affair, and consists of many stages; the revision is arranged to take place once every thirty years. In the first place, every separate estate or holding is demarcated by permanent marks on the ground; and disputes between neighboring right-holders are investigated and decided. Every estate or holding is then surveyed and mapped, all boundary-marks, wells and buildings being shown on the field or cadastral maps. After the field maps are prepared, the next process is to classify or record each field according to its productive value, as evidenced by its soil, the amount of its produce, or by the rent paid by the farmer to the landlord. A record is at the same time drawn up of all rents paid, and of all rights, whether landlord rights, or tenant rights, or rights of user, over all the ground, buildings, wells and trees shown in the map. Then the assessing officer (or settlement officer, as he is often called) compiles the information obtained for all the lands in a circle of villages; and on a review of all these data, of the past fiscal history of the tract, of the range of prices, of the accessibility of markets, and of other general considerations, he proposes government rent rates or revenue rates for the several classes of lands in the circle. The rent rates or revenue rates proposed by the settlement officer, and the grounds on which they were based, are then investigated by a superior officer, and are not adopted until they have been accepted or modified by the latter. The rent averages in most cases at one-half the gross produce of the land.

In provinces where the zamindari tenure prevails, that is, where single proprietors or proprietary brotherhoods possess large estates of several hundreds or thousands of acres, the state revenue is assessed at an aliquot part (usually about one-half) of the ascertained or assumed rental. The revenue, though it is fixed with reference to acreage rates on the land actually cultivated, is assessed on, and is payable by, each estate as a whole; the assessment remains unchanged for the 30 years, or other period of the settlement; the proprietor can bring as much as he likes of his waste and fallow land under the plough; and it is only on reassessment at the end of the term of the settlement that the state obtains any increase of revenue on account of the extensions of cultivation during the settlement period. In provinces where the rayatwari tenure prevails, that is, where each petty proprietor holds directly from the state, generally cultivates his own land, and has no landlord between himself and the government, the revenue is separately assessed at an acreage rate on each petty holding, and land revenue becomes payable at once, or after a short term of grace in the case of uncleared lands, on all extensions of cultivation. The rayatwari proprietor is at liberty to throw up his holding, or any portion of it, at the beginning of any year, after reasonable notice; the zamindar, or large proprietor, engages to pay the revenue assessed upon him for the term of the settlement.

The land revenue assessment was fixed permanently more than 100 years ago on the greater part of Bengal, about a third of Madras, and certain southern tracts of the Northwest now the United Provinces, paying in all about $14,250,000 a year. In the temporarily settled tracts, comprising the rest of India, it is fixed periodically for terms of 12 to 30 years. In the nine chief provinces (Bengal, Bombay and Sind, Madras, the United Provinces of Agra and Ouah, Central Provinces, Punjab, Burma, Assam, Berar) the number of rayatwari holders is about 273,000, of whom none belong to Bengal, Punjab, and the United Provinces and Oudh. The total number of zamindars and village communities is about 318,500, of which only Sind and Berar have none. The total number of holdings is thus about 591,500. In the greater part of Bengal

land is held by zamindars under a permanent settlement, but the tenants are protected by recent legislation. The rayatwari system is the prevalent one in Madras and in Bombay a similar system has been established. In the latter province the cultivators are now protected by law against the extortions of the money-lenders. The village community is still common in the United Provinces and the Punjab. In Oudh much of the land is held by talukdars, who have been granted certain privileges which are denied to the zamindars.

Agriculture.— The total area accounted for in the agricultural returns for 1920 was 754,947,782 acres, of which 88,323,320 are under forest, 145,769,969 not available for cultivation, and 165,549,500 culturable waste and current fallows. The net crop-yielding area is 222,825,487 acres, or, taking account of land cropped several times in a year, 300,000,000 acres. The three chief food-grains of India are rice, millet, and wheat. Rice is the staple food of about a third of the population, and was grown on 81,256,000 acres in 1922, but it is nevertheless essentially a local crop, which can be cultivated with profit only under exceptional circumstances. Of the total rice area 40 million acres belong to Bengal, where it is the staple crop, and about seven million each to Madras and Burma. Over 90 per cent of the cultivated area of Lower Burma is under rice, and it is grown on nearly three quarters of the area of Assam, about one-third of that of the Central Provinces, a quarter of that of Oudh, while it is of importance also in the United Provinces and Sind. It is grown to a less extent in the Punjab and Bombay. Rice is also cultivated by hill tribes in all parts of India. In Bengal there are two chief rice harvests in the year, the *áus* or early crop, chiefly for local consumption, and the *áman* or winter crop, chiefly for export; but in Lower Burma, whence most of the exported Indian rice comes, there is but one harvest, corresponding to the Bengal winter crop. The total area under wheat was in 1922, 28,234,000 acres, mainly in the Punjab, (7½ million), where it is the leading crop, the United Provinces of Agra and Oudh, the Central Provinces, Bombay, Central India and Bengal. The area under the various kinds of millet and maize, which constitute the food of poor people as well as cattle, is 43 million acres, chiefly in Bombay (13½ million), Madras, Punjab, United Provinces, Central Provinces, Sind, Oudh, Bengal and Upper Burma. The chief varieties of millet grown in India are *joár*, or *jawári*, or *cholam*, great millet (*Sorghum vulgare*); *bájra*, or *kambu*, spiked millet (*Pennisetum typhoideum*); and *ragi*, or *náchani* (*Eleusine coracana*), grown chiefly in Southern India. About 8,000,000 acres are sown with barley, chiefly in the upper Ganges valley, the Himalayan valleys, and the Punjab. Gram crops or pulses, especially chick-pea, green-gram, horse-gram, lentil and pigeon-pea, take up 10 million acres. The large native demand for oil has been reinforced in recent times by a rapidly-increasing foreign demand, and in consequence the cultivation of oil-seeds has greatly developed. They are grown in many parts as a second crop on ground from which rice or some other food crop has already been taken. The chief varieties cultivated are linseed, rape-seed, mustard-seed, sesamum (*til* or gingelly), ground nut and castor-oil, and the total area occupied by them is 16 million acres, chiefly in Bengal, Bombay and Sind, Madras, Central Provinces and Punjab. The area under ground-nuts in Bombay and Madras is about 1,663,000 acres. The cultivation of vegetables for household use is general, and near some of the towns it is carried on more extensively. Potatoes thrive best in the more elevated tracts. Among cultivated fruits are the mango, guava, orange, melon, citron, lime, fig, plantain, pineapple, pomegranate, tamarind, shaddock, jack, papaw and custard-apple. The area under sugar-cane is about 2,375,000 acres in Bengal (especially Orissa), United Provinces, Punjab, Oudh, Madras and Bombay. Jaggery sugar is made from the bastard date-palm which is grown for this purpose in the neighborhood of Calcutta and in northeastern Madras. The tea crop is one of great and increasing importance, and occupies about 710,000 acres, of which 400,000 are in Assam, the rest being in Bengal, Punjab, United Provinces, Madras, Burma and native states. With the exception of a few hundred acres in Burma, Assam, etc., the whole of the coffee-growing area, amounting to about 280,000 acres, is in Southern India, in Mysore, Koorg, Madras, Trayancore and Cochin. The chief cinchona plantations are the government ones at Darjiling and in the Nilgiris. The tree was introduced by the Indian government.

Cotton is one of the most valuable vegetable productions of India. The total area under the cotton-plant, including the Native states, is 18,436,000 acres in 1922, distributed thus: Bombay and Sind (5,000,000), Berar (2,500,000), Hyderabad (1,700,000), Madras (1,400,000), United Provinces of Agra and Oudh (1,250,000), Punjab (1,750,000), Central Provinces (1,000,000), and smaller areas in Central India, Rajputana, Burma and Bengal. Next in importance to cotton among Indian fibres comes jute, which is cultivated in eastern Bengal along the valleys of the Ganges and the Brahmaputra, accounting for 2,377,000 acres. The cultivation of the mulberry, for the rearing of the silk-worm, is chiefly carried on in eastern and northern Bengal, with Murshidabad as a centre. The indigo industry is one of the oldest in India, but it is at present in a languishing condition. The area under the plant is about 314,000 acres. The opium poppy is cultivated in Behar and the United Provinces of Agra and Oudh, in the Punjab and in the native states of Rajputana and Central India, occupying in all about 200,000 acres. (See below under *Finance*). Tobacco is grown in every district for local consumption. Among the numerous minor cultivated vegetable products of India are turmeric, chillies, ginger, coriander, aniseed, black cummin, fenugreek, pepper, cardamoms, betel-pepper, areca or betel-nut palm, cocoanut palm, palmyra palm and date-palm. Experimental cultivation of rhea, rubber, sisal-hemp and other valuable economic plants has been carried out on the experimental farms maintained by government in various parts of the country.

Stockraising.— Horned cattle are used in agricultural operations throughout all India, except Sind and the Punjab, where camels generally take their place. The total number of cattle in India is over 120,000,000, of sheep and goats 40,000,000, of horses, ponies, mules and donkeys, 2,500,000, and of camels about 250,000. There are large numbers of buffaloes in all parts of the country. A public veterinary department

attends to the improvement of the breeds of horses, ponies, mules and cattle, the prevention of disease among domestic animals and the provision of veterinary instruction. Its operations are mainly confined to Northern India, where the conditions are most favorable for the breeding of horses for military purposes.

Commerce.— From a very early period down till comparatively recent times Western traders visited India in order to obtain the gold and silver, jewels, spices and other costly products for which India was then celebrated, but the present foreign trade of India has developed under British rule and rests on an entirely different basis. In the year 1700 the total value of the exports from India was under $5,000,000, in 1834 the value had risen to $50,000,000, and in 1913 goods and treasure to the value of about $800,000,000 were exported every year. In 1913–14 the total value of private imports by sea and government imports of stores, as well as treasure was $782,492,030. The total value of private exports of Indian merchandise, foreign merchandise re-exported, government and treasure was $853,630,255, the total sea-borne trade being $1,636,122,285. The chief articles of import were: cotton woven goods, metals and hardware, oils, chiefly petroleum, sugar, railway material, machinery and mill-work, cotton yarns, chemicals, medicines, dyes, woolen goods, silk, raw and manufactured, provisions, liquors and apparel. The chief exports were: jute, raw and woven, husked rice, hides and skins, oil-seeds, raw cotton, tea, opium, cotton yarns, wheat, indigo, coffee, raw wool and cotton woven goods. The proportion of trade directly with European countries is about 63½ per cent omitting the trade with Egypt much of which really goes to Europe. The trade with the United Kingdom is over 60 per cent of the trade with Europe and nearly 45 per cent of the total trade. Next to the United Kingdom the chief countries trading with India are China, Germany, United States, Straits Settlements, France, Japan, Belgium, Ceylon, Austria, Hungary, Italy and Russia. The figures for 1913–14 show that, while Indian imports of American goods were valued at about $15,967,000, Indian exports to America amounted to $72,500,000. The chief articles of export appear to be gunny bags and cloth, of which latter America takes more than all other countries. The trade of India with America, however, is only of short standing, but wisely organized, is capable of being greatly expanded. Before the War, Germany supplied many things this country should furnish, particularly in the electrical and chemical lines, in which it at present holds the market. Other important articles of Indian export are tea, jute and jute manufactures, wheat, oil-seeds, rice, leather, wool, indigo, coffee, teak-wood, cotton and lac. The foreign trade of India in 1921–22 was estimated at: imports, of merchandise, 280,71,21,848 rupees; of treasure, 31,29,90,526 rupees; exports of merchandise 2,48,65,76,526 rupees; of treasure, 19,06,73,144 rupees. (Value of rupee in 1922 about three to the dollar.) India has many seaports of great importance. The value of merchandise and treasure carried in coasting vessels during 1921–22 was 218,-90,44,691 rupees. The trade across the land frontiers is steadily increasing, the chief item among imports being food grains, and among exports cotton goods. Much greater than her trade with foreign countries is the internal trade of India, but no returns of its amount are available. It is mostly in the hands of natives, and to a large extent in those of particular groups or castes. It is still carried on, as it has long been, at village markets, town bazaars, religious fairs and similar gatherings, but the development of railway and canal communication and the transformation in the system of agriculture have already altered its character in many ways.

Manufactures.— The domestic industries of India, such as weaving and spinning, pottery, brass-work, iron-work and art work of many kinds, continue to be practised after ancient methods all over the Empire of India. But Indian fabrics and products, made on a small scale by workers at their homes, have for years past been giving way before the cheaper, less artistic, and often less durable cotton yarn and fabrics, and the iron or steel products of British factories. Meanwhile an important manufacturing industry has been growing up, and steam-power factories are at work, among which those for spinning and weaving cotton, for spinning and weaving jute, for making paper, for husking and cleaning rice, for sawing timber, and for brewing beer, are the most important. Steam power is also largely employed in factories, on tea gardens and indigo estates. In 1921 the number of cotton-mills in British India and native states was 284, containing 118,434 looms and 7,831,652 spindles, and giving employment to 282,297 persons. Of these mills over one-half were in Bombay Province, the rest being in Madras, Bengal, Central Provinces, United Provinces, Burma, Punjab and Berar, besides some of the native states. The number of jute-mills was 75 containing 42,500 looms and 885,895 spindles, and employing over 264,373 persons. All the jute-mills are in Bengal, except one in Cawnpore, which is the chief manufacturing centre of the United Provinces. Four woolen mills produce blankets, serges and cloths worn by the army and the police. The largest brewery is at Murree, in the Punjab Himalayas. Among other industrial works of importance are silk-mills, soap-factories, tanneries, iron and brass foundries, sugar-factories, coffee-works, cotton-presses and ginning-factories, jute-presses, rope-factories, oil-mills, cutch and lac factories, flour-mills, ice-factories, pottery and tile factories, bone-crushing works, tobacco and cigar factories, silk filatures, glass-factories, dye-works, indigo-factories, printing-pressses and dairy farms. The total number of persons employed in all these manufacturing industries is about 1,238,410. The daily wages of unskilled labor in a factory vary, according to locality, from 2 to 4 annas (4 to 8 cents).

Shipping and Navigation.— In 1921–22 8,037 vessels of 15,654,967 tons burden entered and cleared the ports in British India, as against 8,617 vessels of 17,386,408 tons in 1913–14. Of t'ese 4,799 were of British nationality, 1,575 native, 696 British Indian and 987 foreign.

Railways and Roads.— The first Indian railway, from Bombay to Thana, was opened in 1853. The main trunk lines constructed from that time till about 1875 were built and managed by private companies on whose capital the Indian government guaranteed a fixed rate of interest, generally 5 per cent. The government in return for this assistance, exercised a general control over the companies, and reserved the right of buying the undertakings at specified dates on stated terms. In 1870 Lord Mayo initiated the policy of railway construction by direct state agency, but in more recent times several lines have been constructed by "assisted companies." Several of these latter lines have been taken over by government. There are also native state railways constructed from capital borrowed by native states, but generally worked by a staff employed by the government of India or by the trunk railway companies to whose lines they serve as feeders.

The importance of railroads in India is largely increased, in a governmental sense, by reason of their forming strategical links between the various military cantonments through which the vast Indian population is held in check by a comparatively small army of British soldiers. This, more than any other incentive, has hastened the development of railways in India.

The main lines are four in number, and are known as the Bombay-Calcutta, Madras-Calcutta, Calcutta-Simla and the Bombay-Madras lines. The first crosses the great northern plain, the last the great southern plain of India, and are both connected by means of branch lines with all the large cities of the empire. These great trunk lines have also been extended to the farthest limits of India, and even into adjoining territories, as where the line which crosses the Indus at Sukkur enters Afghanistan, the terminus being not more than 60 miles from Kandahar. There is also the Burman line, which passes up the valley of the Irawaddy in the direction of the Chinese frontier. These three main lines, with their several offshoots, may be roughly sketched as follows: In the north, a direct line from Bombay on the west coast to Calcutta on the east coast; a line to Benares from Bombay; a direct line from Calcutta to Peshawar, on the Afghanistan border, by way of Benares, Delhi and Lahore; a line from Lahore to Karachi, with the branch line between these two cities to Kandahar. In the south, the main line between Bombay and Madras through Hyderabad; the line from Bombay to Goa, and from Goa to Madras, with lines connecting with Calicut and with the line from Madras to Tuticorin in the south. Since 1916 a railway built across "Adam's Bridge" at a cost of $3,700,000 connects Ceylon with India. In Indo-China, the main line from Rangoon to the Chinese frontier, by way of Mandalay, and with an extension to Bhamo and another to Meaday. (It is proposed to extend the Bhamo line to Bishi and the main line to Yun-nan in China with offshoots to Tching-tou and Hai-pong).

The total mileage of railways open in India on 31 March 1922 was 37,266, divided as follows: State lines worked by the state, 7,698 miles; state lines worked by companies, 19,107 miles; branch line companies' railways under guarantee and rebate terms, 2,265 miles; companies' lines subsidized by the central or local governments, 2,306 miles; unassisted companies' lines, 78 miles; district board lines, 237 miles; companies' lines subsidized by district boards, 307 miles; Indian state lines worked by Indian states, 2,951 miles; Indian state lines worked by the main line, 1,483 miles; companies' lines guaranteed by Indian states, 760 miles, and lines in foreign territory worked by British Indian railway companies, 74 miles. The total capital outlay of these railways till the end of 1922 was 6,56,06,24,000 rupees; the total number of passengers carried in 1922 was 550,886,900; and the total weight of goods and live stock carried 86,248,000 tons. The chief highways are well metalled with a kind of limestone called *kankar*, but in Lower Bengal and similar districts, where there is no available stone, roughly-made bricks are used for road-metal. Many of the roads are planted with avenues of trees.

Posts, Telegraphs and Telephones.— The number of post-offices in India in 1922 was 69,674. The total number of letters and post-cards and all pieces of mail was 1,455,198,740. The Indian telegraph system consisted in 1922 of 91,760 miles of line, 412,023 miles of wire. The number of telegraph offices is about 7,000 and the annual number of messages over 20,-600,000. There are telephone companies at important towns, such as Bombay, Calcutta, Karachi, Madras, Maulmain, Rangoon and Ahmadabad. India is now in direct telegraphic communication with the Straits Settlements and the Australian colonies, with Europe via Suez, via Teheran and via Turkey, with the East Coast of Africa and with China via Bhamo; and there are several wireless telegraphic stations under government control.

Canals and Irrigation.— In some parts of India, such as Sind, cultivation is impossible without irrigation, while in others, such as much of Lower Bengal, irrigation may be regarded as quite unnecessary; but in the greater part of all the provinces the rainfall is either insufficient for the proper cultivation of the soil, or so uncertain as to expose the agriculturists to the constant risk of scarcity and even of actual famine. Hitherto irrigation has had only a secondary place in the governmental development of India, the attention of the administration having run more to railways. The profit on the railways is, on an average, 5 per cent, while the expenditure on irrigation works on which only $125,000,000 have been spent, the profit has averaged 8.22 per cent; on the Eastern Jumna canals the profits rise to 25 per cent. The annual irrigation expenditure under the present Indian budget comes to only $7,500,000 for major and minor works together.

Many of the irrigation works now administered by the Public Works Department are simply old native works restored, and in some cases extended or improved. Tank irrigation is common in some districts, especially in southern India, and the tanks are mostly of native origin. Many old tanks, however, have been repaired or improved by the British government, and new ones have been constructed in Madras (where there are now 60,000 tanks), the Bombay Deccan and Ajmir Merwara. In parts of Baluchistan, where the rainfall is scanty and capricious, water for irrigation purposes is drawn from underground springs by means of tunnels driven into the hillsides. The most common method of irrigation in India, however, is that by wells, which prevails over large areas

in all the provinces. Canal irrigation was practised to some extent by the native rulers, but all the important canals have been constructed since the British occupation. Irrigation canals are of two kinds, inundation and perennial. The latter are furnished with permanent headworks and weirs, and are capable of irrigating large areas throughout the year, independently of the local rainfall; while the latter, which are peculiar to Sind and the Punjab, are simply earthen channels supplied with water by the annual rise in May of the Indus and its affluents. Many of the perennial canals are, either in whole or in part, used for navigation, and there are, besides, a few canals used for navigation alone. In 1913–14 throughout India, 20,446,248 acres were irrigated by canals; 6,303,740 acres by tanks; 13,866,918 acres by wells and 6,219,113 acres by other sources. State irrigation works accounted for nearly 25,000,000 acres in 1913–14. Aside from interest charges, the net revenue from these works was about $21,125,000, while the estimated value of crops was $271,250,000.

Money, Weights and Measures.— By an act passed in 1835 a uniform monetary system was established throughout India, with the Madras silver rupee of 180 grains, .916 fine, as the monetary unit. The rupee was subdivided into 16 annas, and each anna into 12 pies (or four pice). Silver was made the universal standard of value, and the silver rupee and half-rupee were declared to be legal tender to any amount. The other smaller coins were made legal tender up to the value of one rupee; 100,000 rupees are called a lakh or lac, and 100 lakhs a crore. Under this system large sums are punctuated differently from the usual European method. For instance, the Indian Post-Office Savings banks' statistics show that in 1913–14, 9,824 banks with 1,638,725 depositors had to their credit 231,675,467 rupees, or according to the Indian method 23,16,75 467 rupees, reading as 23 crores, 16 lakhs and 75,467 rupees.

The coins under this system are: Silver— Rupee, half-rupee, quarter-rupee and one-eighth rupee; Bronze or Copper— Three pies (or a pice); six pies, one pie. There are also gold coins called mohurs, but they are not a legal tender, and there is no fixed ratio between them and the silver coins. The rupee was formerly valued at 48 cents, but it has fluctuated greatly, mainly downward. In January 1895 it was nearly as low as 24 cents; but since 1898 the sterling value of the rupee has been about 32 cents. In view of the steady depreciation of silver, and the consequent financial embarrassments and burdens to which the government of India was subjected in its dealings with gold-standard countries, an act was passed by the Governor-general's Legislative Council in 1893 providing for the closing of the Indian mints to the unrestricted coinage of silver for the public. Notifications were issued simultaneously providing (1) for the receipt of gold coin and gold bullion at the mints in exchange for rupees at a ratio of 1s. 4d. (or 32 cents) per rupee; (2) for the receipt of sovereigns and half-sovereigns of current weight at treasuries, in payment of government dues, at the rate of 15 rupees for a sovereign and 7½ rupees for a half-sovereign; and (3) for the issue of currency notes in Calcutta and Bombay in exchange for gold coin or gold bullion at the rate of one government rupee for 1s. 4d. By a notification of 11 Sept. 1897, sovereigns and half-sovereigns of current weight are also received at the reserve treasuries, at the rate of rupees, 15 for the sovereign.

An act (XXII of 1899) declared the sovereign legal tender, 15 rupees to the sovereign. It was, however, decided not to coin gold in India, a proposal to coin gold is now under consideration.

The Coinage Act of 1906 provided for the introduction of a subsidiary nickel one-anna piece and the substitution of a bronze currency for the existing copper coins. The coinage of copper was accordingly discontinued with effect from 1 Aug. 1906. The issue of the nickel one-anna piece was commenced with effect from 1 Aug. 1907.

Since 1900 rupees have been coined as required to meet public demands, the government purchasing the silver and paying for it mainly with the gold accumulated in the paper currency reserve. The entire profit accruing to government on the coinage up to 31 March 1907, and during the year 1912–13, and half such profit for the years 1907–08 and 1908–09 were placed to the credit of a separate fund termed the gold standard reserve, with the object of ensuring the stability of the currency policy of the government. Any profit arising from this source in future will be credited entire to the gold standard reserve, until such time as the gold and gold securities in the gold standard reserve shall attain to a total of 25,000,000 sterling. At 31 Aug. 1921, the reserve amounted to about 39,629,470 pounds sterling, inclusive of 4,000,000 lacs of rupees held in India.

On 16 July 1861, an act was passed by the government of India providing for the issue of a paper currency through a government department of Public Issue, by means of promissory notes. Circles of issue were established from time to time, as found necessary, and the notes were made legal tender within the circle for which they were issued, and rendered payable at the place of issue, and also at the capital city of the presidency. Subsequent legislation has relaxed the rigidity of the circle system. Notes of the values of 5, 10, 50 and 100 rupees are now legal tender throughout British India, and the limitation of currency to the circle of issue is confined to notes of higher denominations. There are now seven circles of issue with their headquarters at Calcutta, Bombay, Madras, Rangoon, Cawnpore, Lahore and Karachi.

By the Measures of Length Act of 1889 the British Imperial yard of 3 feet or 36 inches was made the standard of length for the whole of British India. The most important of the old native measures of length was the *guz* of Bengal, which was practically equal to a yard. An act was passed in 1871 to prepare the way for the adoption of a uniform system of weights and measures of capacity throughout British India. The unit and standard of weight established by the act is the *ser*, which is equal to a kilogram or two and one-fifth pounds. The unit of capacity was declared to be a measure containing one ser of water, at its maximum density, weighed in a vacuum, and is thus equal to a litre or one and three-quarters pint. Among native weights the most important are the tola (Bengal) of 180 grains, and the Imperial or Indian maund of 40 seers, equal to 822/7 pounds.

Government.— The Indian Empire's present form of government is established by various parliamentary statutes consolidated in the Government of India Act of 1915 as amended in 1916 and 1919. All of the territories originally under the government of the East India Company are vested in the Crown and all of the powers of the said company are exercised in the name of the sovereign; all revenues, tributes and other payments are received in his name and are disposed of for the purposes of the Indian government alone. Until 1907 India was governed by a bureaucracy of officials, of which the more responsible were British. She had no representative system, save the legislative councils in her provinces, which were nominated. These councils had been set up by an act dated 1892. The Empire of India consists of (1) the directly governed provinces, with a population of about 240,000,000; and (2) the native states, each of which has its own prince or chief, with a total population of about 80,000,000. There are about 700 "states" of which 70 are of a considerable extent. Under the unreformed system, the provinces were governed by the Viceroy and Governor General, sitting in Calcutta, with a Council, wholly nominated. Each province had a governor, a lieutenant-governor or administrator of lower rank. The hierarchy of officials was highly centralized. In 1909, Viscount Morley, then Secretary for India in London, secured passage for the Indian Councils Act. The measure provided the provincial governors with an executive council or cabinet of four ministers, which councils hitherto had been authorized only for Bombay and Madras and there consisted of only two ministers. It also admitted elected members to the legislative councils, established by the act of 1892, and gave these councils the right to discuss finance. These concessions were with difficulty passed through the House of Lords, yet it was clear that they did not begin to satisfy advanced opinion among the intellectuals of India. In 1911 King George held a Coronation Durbar at Delhi. He there announced that this city— the ancient seat of the Mogul empire —would be substituted for Calcutta as capital of India. On 20 Aug. 1917, E. S. Montagu, Secretary of State for India, announced to the British House of Commons that he had been authorized to proceed to India, there to discuss a far wider scheme of self-government than any contemplated prior to that date. On 22 April 1918, the so-called Montagu-Chelmsford report was issued. Based on its recommendations stands the constitution of India, as now developed.

At the head of affairs, there is still the Viceroy and Governor-General, whose term of office is usually five years. While the Secretary of State for India is still constitutionally responsible to the British Parliament and Cabinet for the government of the dependency, actual control is passing more and more every year to the authorities within India herself. The ruling princes of the native states have been organized into a Council of Princes which meets at Delhi for the consideration of matters affecting those territories. At Delhi, there has been established also a parliament, with two chambers. The Upper House or Council of State consists of not more than 60 members of whom not more than 20 may be officials. This Council of State corresponds to the senate or second chamber in the self-governing dominions. The life of the Council is five years. The Lower House, or Legislative Assembly, consists of 144 members, of whom 41 are nominated and 103 elected by popular vote. Of the nominated members, 26 are officials. The normal life of the Legislative Assembly is three years and this period may be lengthened or shortened by the Governor-General at his discretion. In the event of differences between the two chambers, there is a provision for joint sittings. The procedure in the Parliament at Delhi is based upon precedents established at Westminster. The language used is English which has become the most convenient medium amid the numerous languages and dialects spoken by the various Indian races. The Governor-General's Executive Council or Cabinet has a varying number of ministers — eight is usual; there are 11 departments — home, foreign and political, finance, army, public works, revenue and agriculture, commerce, legislative, education and health, railways and the board of industries. While it cannot be suggested that this constitution is as democratic as that of the United States or of Great Britain, and her self-governing dominions, the scheme is said to represent an enormous advance beyond anything previously suggested for a great Oriental country. The reforms include a far-reaching devolution of powers from the central government to the provinces. Up to 1923 eight legislatures had been created, with members as follows: Madras 118, Bombay 111, Bengal 125, United Provinces 118, Punjab 83, Bihar and Orissa 98, Central Provinces 70 and Assam 53. In these legislatures, not more than 20 per cent of the members may be officials, while 70 per cent must be elected. A small minority are nominated and non-official. The normal term is three years. The principle underlying the constitution has come to be called "dy-archy." Broadly, it means that certain subjects are "transferred" to the control of the legislatures while other subjects are "reserved" in the control of the officials. The transferred subjects include, with reservations, local self-government, medical administration, public health and sanitation, education, public works, agriculture, fisheries, co-operative societies, excise, registration, development of industries, adulteration, and religious and charitable endowments. By the scheme of reforms, further subjects can be "transferred" from time to time and so brought under popular control.

Finance.— The introduction of the reforms of 1 April 1921 has brought about a complete change in the financial relations between the central and provincial governments of India. Prior to that time the latter had no separate revenues exclusively their own. Their resources were obtained mainly from a share of divided heads of revenue and from lump assignments from Imperial revenue. Definite sources of revenue have now been allocated to the provincial governments. Central or Imperial revenues are derived from opium, salt, customs, income tax, tributes, postoffice and telegraphs, railways, mint, military services, etc.; provincial revenues from land revenue, stamps, excise, forest, registration, irrigation and civil departments. Provincial governments have to pay annual contributions to the central government. The budget estimate of the central government for 1922–23 was: Revenue, 1,33,22,78,000 rupees; expenditures, charged to revenue, 1,42,39,06,000 rupees.

Defense.— Normally the military forces in India consist of the British Regular forces, the Native Army, the Auxiliary force and the Imperial Service troops. They are administered by the headquarters staff and the Army and Marine department, both under the supreme control of the commander-in-chief, who is a member of the Viceroy's Council. For training and inspection the forces are organized into the Northern, Southern, Eastern and Western commands and the Burma independent district. The British Regular forces are paid by the Indian exchequer. The Tank Corps and Royal Air Force are wholly British. The British Regulars are brigaded with the native troops. The Auxiliary force is composed of persons of British extraction; the Imperial Service troops are raised and maintained by native states, but are trained by British officers.

Ethnology.— India is inhabited by numerous peoples belonging to several distinct groups or families. Previous to the Mohammedan ascendency the dominant race were the Hindus, who, however, were not the aboriginal inhabitants nor even the first invaders. From the northwest of India, through Kashmir and down the valley of the Indus, and from Tibet through the passes of the Himalayas, the inhabitants of northern Asia from a very early period migrated southward to the milder and more fertile plains of India. Two great successions of these invasions are recognized as having taken place before the period of authentic history. The first immigrants, of dubious ethnological connections, but commonly known as the Tamil races, appear to have overspread the entire peninsula. Following them the Sanskrit-speaking peoples, called the Hindus, of Aryan speech, dispossessed the Tamil races, and superseded their language in the whole of India north of the Nerbudda. The Hindus subsequently descended into the peninsula and penetrated as far as Cape Comorin; but though their influence on the languages of southern India was considerable in the way of introducing new terms, the grammar and construction of the Tamil languages maintained their place in the districts south of the Nerbudda. The native tribes were not exterminated by these invasions, but are still to be found under various names, as Bhils, Catties, Coolies, Gonds, etc., inhabiting the fastnesses of the mountain-ranges in Bengal, the Vindhya and Satpura Mountains, the Ghâts, etc. The hill tribes and other aborigines in all India are estimated at 70,000,000.

Population.— The first census of all India was taken in 1871–72, but it was not till that of 1891 was taken that a really reliable and comprehensive statistical account of the people of India was available. In 1871–72 the total population of India was returned at 240,931,521, in 1881 at 253,793,514, in 1891 at 287,223,431, in 1901 at 294,266,701; in 1911, 315,156,396, in 1921, 318,942,480 of which 247,003,293 were under immediate British authority. The total number of Europeans was only 135,995.

France still possesses in India Pondicherry, Karikal, and Yanaon, on the east coast of Madras; Mahé, on the west coast of Madras, and Chandarnagore on the Hugli, north of Calcutta. To Portugal belong Goa, Damão, and the small island of Diu, on the coast of Bombay. These French and Portuguese possessions have a total area of 1,754 square miles and a popuation of 852,752.

Education.—A system of education for India was inaugurated in 1854 in conformity with the instructions of the home government, and the despatch of Sir Charles Wood (afterward Lord Halifax) of 19 July 1854 is the basis on which the educational system still rests. The fundamental principle of the despatch was that the native languages should be made the medium of communicating European knowledge. Examining universities with affiliated colleges were to be founded, and English and vernacular elementary schools were to be established. The despatch enumerated five government colleges in Bengal; the Sanskrit College and Mohammedan Madrasa at Calcutta; five colleges in the United Provinces; the Elphinstone Institution, Puna College and Grant Medical College in Bombay; the High School at Madras and several missionary schools, as proper to be at once affiliated to the universities. In 1857 the three universities of Calcutta, Madras and Bombay were formally incorporated by law as examining bodies based on the model of the University of London as then constituted. A somewhat different university, with teaching powers, was established in 1882 at Lahore in the Punjab, and in 1887 a fifth university was founded at Allahabad for the northwest provinces. The Education Commission of 1882–83 extended the system of Wood's despatch by placing education on a more popular basis and giving greater recognition to indigenous schools and the first proposals for extending education to Indian women were made by this commission. Educational institutions in India are officially divided into two classes: (1) Public schools, in which the course of study conforms to the standards prescribed by the department of public instruction or by the university, and which either undergo inspection by the department, or else regularly present pupils at the public examinations held by the department or by the university. These institutions may be under either public or private management, and among them are many schools receiving grants-in-aid. (2) Private schools, comprising all which do not fulfil the above conditions. The three main grades of institutions through which the system of education operates are: (1) Primary schools, which aim at the teaching of reading, writing and such elementary knowledge as will enable a peasant to look after his own interests; (2) secondary schools, either English or vernacular; and (3) colleges, the students in which, having passed the matriculation examination of a university, are reading for the further examinations required for a degree. There are also many other colleges teaching special branches of knowledge, such as medicine, law, and engineering, and special colleges for sons of native chiefs and noblemen. In Burma primary education is still very largely in the hands of Buddhist monks. Outside of a few exceptional districts, female education is exceedingly backward in India, but slow progress is being made. There are schools of art in Madras, Calcutta and Bombay, and many of the chief towns have good museums. Many normal schools have been established for the special training of teachers.

The total number of colleges in India in 1920 was 200 of which only 16 were for females.

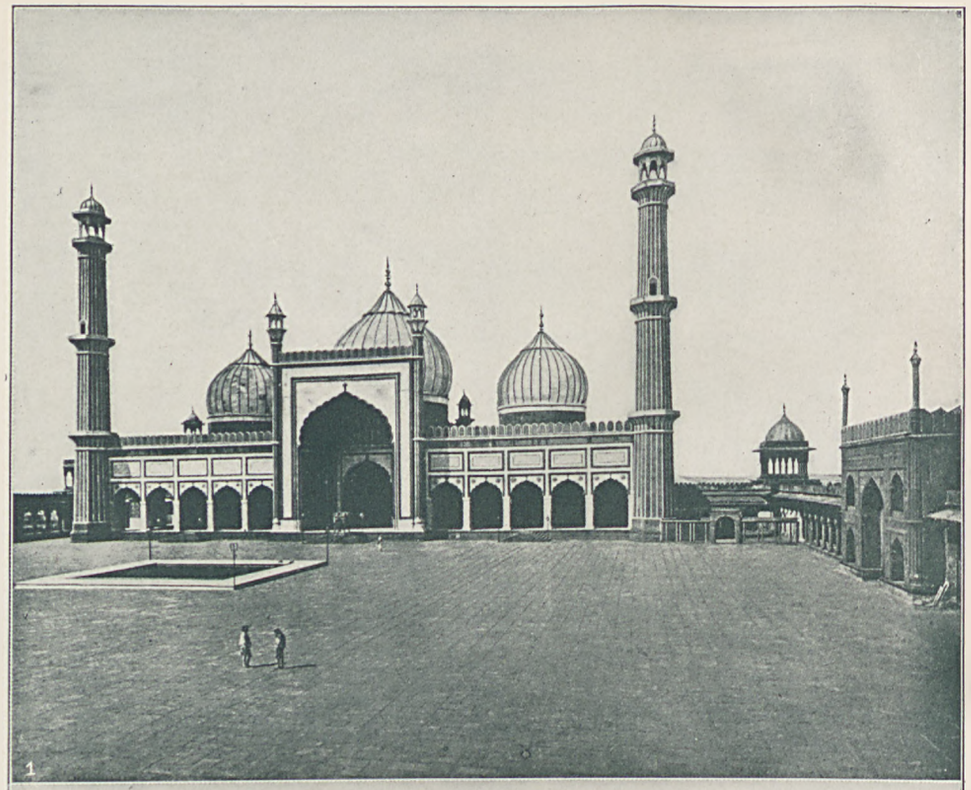
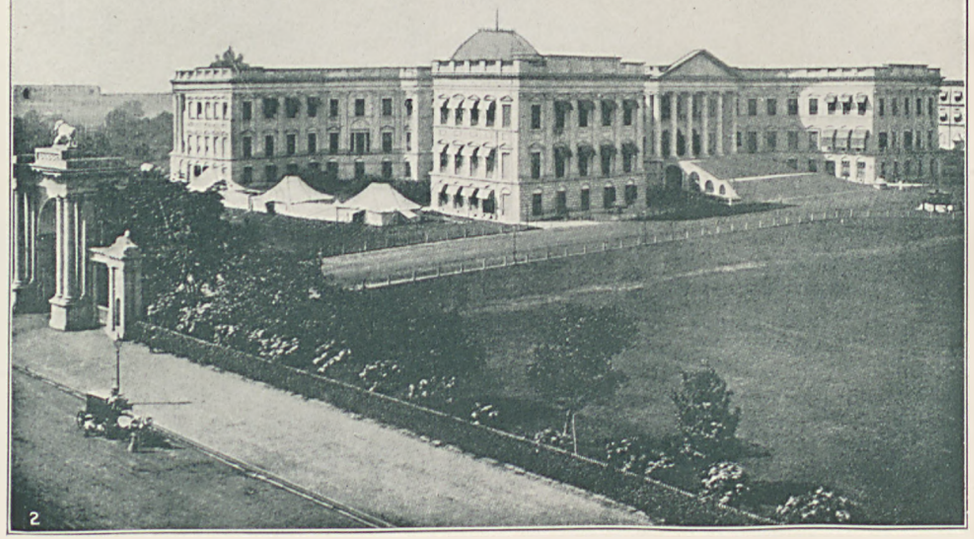
2 A High-caste Maiden, Madras





1 Jumma Musjid, Delhi

2 Government House, Calcutta

The number of students in these colleges was 65,916. Secondary schools numbered 8,708, with 1,281,810 pupils, 117,528 of the latter being females. The number of primary schools was 155,344, with 4,956,988 male and 1,176,533 female pupils. The total number of training and other special schools was 4,090, with 131,592 pupils. Beside all these, there were 34,623 private institutions, with 523,076 male and 70,310 female scholars. The total number of educational institutions of all kinds was thus 202,981, of which 17,068 were for females, and the total number of persons under instruction, 8,206,225, of whom 1,377,021 were females. It has been estimated that 22.2 per cent of the boys of school-going age attend school, but for girls the percentage is only 2.3. In nearly all branches of education in India the missionaries have been the pioneers, although at present their work is not important.

Languages, Literature, Art, Music.— See INDIA, LANGUAGE AND LITERATURE OF; INDIA, ART AND ARCHITECTURE OF; INDIA, MUSIC OF.

Religions.— The religions of India like the races are numerous. The most important is the Hindu or Brahmanical, which is very ancient. The earliest period of the Hindu religion is called the Vedic, from the Vedas or sacred books in which its records are preserved. These exhibit several marked phases of transition. The earliest date of the Vedic literature cannot be satisfactorily determined, either from philological or internal evidence. Its latest writings are not more recent than the 8th century B.C. Each Veda consists of three parts, the Sanhitâ, a collection of mantras or hymns, the Brâhmana, which contains the doctrinal and ceremonial development of the religion and the Upanishads. The worship represented in the greater number of the hymns is that of God as nature: Indra, the cloudless firmament; the Maruts, the winds; Ushas, the dawn; Vishnu, Surya, Agni and other deities. These deities were invoked for assistance, and were reminded by the suppliants of their former glorious deeds. In the Vedas no attempt is made to classify the gods and assign them particular ranks. In the Upanishads, a systematic attempt is made to solve the problems of creation, of the nature of the supreme being, and of his relations with the human soul. Some of the Upanishads are legendary in form others doctrinal or exegetical. These Upanishads, though not in form philosophical, being professedly founded on the Vedas, contain the germs of the great systems of Hindu philosophy which were afterward developed.

A new era in the history of Hinduism begins with the composition of the two great epics, the Râmâyana and the Mahâbhârata, the latter of which was the product of successive ages. The creed had by this time experienced the influence of the theological and metaphysical speculations of the Upanishads, and had assumed a mystical unity. Brahmâ, Vishnu and Siva, the three emanations of the great soul Brahmâ, representing respectively the creative, preserving, and destroying principles, had become the leading objects of worship.

The third or Purânic period of Hinduism correspond with the period of the Christian Era. The Purânas are discussions upon religion and philosophy, in the form of dialogues conducted by sages. They are designed for popular instruction. The epic legends are amplified and explained. The Vedânta philosophy, which had become the basis of the educated creed, still exercises a favorable influence on the popular worship. The creed of the Purânas is that of the masses in India.

Buddhism arose in India in the 6th century B.C. It prevailed there extensively, and spread itself through the adjoining regions of Asia. It became extinct in India before the 12th century, but still flourishes in China, Japan and in the southeastern regions of Asia, as well as in Nepal and Ceylon. (See BUDDHA). The Jainas or Jains, whose religion is a mixture of the Buddhist and the Brahmanical creeds, are still numerous in Hindustan, and particularly in Gujarat. There are two sects of this creed, called Digambaras and Swetâmbaras. Sikhism is another heretical form of Brahamanism prevalent in the Punjab. There are numerous other minor sects of Hinduism and worshippers of particular gods in the Hindu mythology. The Brahmo-Somaj (q.v.) is a modern Hindu theistic sect. The Parsees or fire-worshippers are descendants of the Persian followers of that religion, who took refuge from Mohammedan persecution on the western coast of India. Their principal emigration was to Surat, and is supposed to have taken place about the end of the 8th century. They were well received in Gujarat. They are now to be found mostly in the mercantile towns in western India, and are most numerous in Bombay. The Mohammedans of India are chiefly native converts, with a very small sprinkling of the descendants of its conquerors from Afghanistan, Persia, Baluchistan and Arabia. They are said to be more liberal-minded than the Mohammedans of western Asia. There is among them a sect of Fakirs like those of the Hindus. There are also numerous Jews in India. On Christianity in India see below under *Christian Missions*. Hinduism recognizes four castes — the Brahmans, or sacerdotal class; the Kshatriyas, or military class; the Vaisyas, or mercantile and agricultural class; and the Sûdras, or servile class. These castes are hereditary. (See CASTE). Such divisions are however, now getting obsolete. Closely connected with the Hindu religion is the collection of laws commonly known as the Institutes of Manu. (See MANU). In the Indian census table of religions (1901) 8,584,349 people are returned as heathens or aboriginals, that is, devotees of some form of animism. Practically, for the purposes of the Indian census, all are classed as animistic who are not locally acknowledged to be Hindu, Mohammedan, Christian, Buddhist, Jew, Parsee, etc., but every stratum of Indian society is in reality more or less saturated with animistic conceptions. Of the total population of British and Native India in 1921, 216,734,586 were registered as Hindus, the greater number of these being in Bengal, the United provinces of Agra and Oudh, Madras, Bombay, Hyderabad and Rajputana. There were 68,735,233 Mohammedans chiefly in Bengal and the Punjab; 11,571,268 Buddhists almost all in Burma; 4,754,079 Christians of whom two-thirds are in Madras and in the Madras States; 3,238,803 Sikhs, chiefly in the Punjab; 1,178,596 Jains, chiefly in Rajputana and in Bombay; 101,778 Parsees and 21,778 Jews mostly in Bombay. See HINDUISM.

Christianity and Christian Missions in India.— The introduction of Christianity into India is variously ascribed by tradition to Saint Thomas the Apostle; Thomas the Manichæan of the 3d century; and Thomas, an Armenian merchant of the 8th century. The earliest Christian church in India of which we have any definite knowledge was Nestorian, but after the Portuguese occupation these Nestorians came into the Roman obedience. In 1663, after the arrival of the Dutch, some of these renounced their allegiance to Rome. In 1665 these latter received from the Patriarch of Antioch a Jacobite bishop known as Mar Gregory, and to this dav they have remained faithful to his Jacobite tenets. Thus, the ancient Nestorian church of southwest India is represented now by two bodies, namely: (1) Catholics of the Syrian Rite, owning the supremacy of the Pope, but retaining the Syrian language and ritual in their services; and (2) the Jacobite Catholics, rejecting the errors of Arius and Nestorius, and following the Nicene creed, though not acknowledging papal supremacy. The spread of the Roman Catholic faith in India was mainly the work of Jesuits from the 16th century onward, the first of these being the celebrated Saint Francis Xavier, who reached India in 1542. The Jesuits were suppressed in the 18th century, but since the re-establishment of the order in 1814 they have made great progress. The Roman Catholics of India are at present organized in seven archbishoprics (Goa, Agra, Bombay, Calcutta, Madras, Pondicherry and Verapoly), and 16 bishoprics (Daman, Cochin, Mailapur, Allahabad, Lahore, Poona, Dacca, Krishnagar, Hyderbad, Nagpur, Vizagapatam, Coimbatore, Mangalore, Mysore, Trichinopoly and Quilon), and there are also several vicars and prefectures apostolic. The earliest Protestant missionaries in India were the Lutherans, Ziegenbalg and Plutschau, who arrived in the country in 1705 and began work at the Danish settlement of Tranquebar. The Lutheran missions were supported from the first by the Society for Promoting Christian Knowledge, and from 1719 till 1844 they were entirely maintained by that body. The celebrated Christian Friedrich Schwarz worked under the auspices of this society from 1750 till his death in 1798. Kiernander, a Dane, was the pioneer of Protestant missionary enterprise in Bengal. He was allowed by the East India Company to settle at Calcutta in 1758, but soon afterward the company changed its policy, and began to prevent missionaries from landing in the country controlled by it. When William Carey, the great Baptist missionary, arrived in 1793, he had to settle on Danish territory at Serampore, 15 miles from Calcutta, and it was not till 20 years later that the company's opposition to missions was withdrawn. Carey was followed at Serampore by Marshman and Ward, whose names will always be associated with his and with the wonderful literary activity begun by him. Other celebrated Indian Protestant missionaries are Henry Martyn and Bishop Heber of the Anglican Church and Dr. Alexander Duff, at first of the Church of Scotland, afterward of the Free Church of Scotland. The head of the Anglican Church in India is the bishop of Calcutta, and under him are the seven bishops of Madras, Bombay, Lahore, Rangoon, Lucknow, Chutia, Nagpur and Travancore. Many American missionaries also work in India.

Judiciary.— The law administered by the courts of India is chiefly based on the enactments of the Indian legislative councils, the statutes of the British Parliament relating to India, the Hindu and Mohammedan laws of inheritance and their domestic law in cases affecting Hindus and Mohammedans, and the customary law affecting particular castes and races. Bengal, Bombay, Madras and the united provinces have each a High Court supreme in civil and criminal cases (but with an ultimate appeal to the Privy Council in England, and somewhat similar tribunals exist in the other provinces. There are numerous courts of different grades throughout the country, and many of the judges are natives of India. Various enactments have been passed for the establishment of local government, and there are now about 740 cities and towns with municipal government in the different provinces under these acts, and local taxation for police and local improvements has been enforced.

Local Government.—All the provinces, except Madras, are divided into divisions, each under an official called a commissioner, and all, including Madras, are divided into sections distinctively designated districts, the district forming the unit of administration. At the head of each district is an officer called a collector-magistrate or deputy commissioner, the former name implying the twofold nature of his duties, since he is not only a fiscal officer charged with the collection of the revenue from the land and other sources, but is also a revenue and criminal judge, both of first instance and of appeal. Police, jails, education, municipalities, roads, sanitation, etc., all come under his supervision; and he is expected to be familiar with the social life of the natives in all its phases. The districts are sub-divided into lesser tracts, known in Bengal as sub-divisions; in Madras and Bombay as *taluks;* in northern India generally as *tahsils.* The unit of police administration is the *thana* or police circle. An important portion of the administrative staff consists of persons who have received appointments in the Indian civil service, after being successful in competitive examinations held in England; these form what is called the *covenanted* civil service. A certain section of the civil service, known as "the statutory civil service," consists of natives specially selected. The native states are generally governed by hereditary princes, who exercise sovereign power within their own dominions. They are more or less controlled, however, by British influence, a British resident, agent or commissioner being stationed at their courts. They have no power to make war or peace, to send ambassadors to each other or to non-Indian states; they can only keep up a certain specified military force, and they may be dethroned for misgovernment.

History.— Little is known of the political history of India previous to the expedition of Alexander to the Indus, 326 B.C. The 20th satrapy of the Persians comprehended, as Herodotus states, part of the northwest of India. Alexander did not penetrate beyond the tributaries of the Indus, and between his invasion and the Mohammedan conquest there is no authentic political history of India, although the territory was divided among a number of

rulers of whom Asoka (q.v.), the founder of Buddhism, was one of the chief. At the time of the Mohammedan invasion a Hindu monarchy was the dominant power in India. The conquest of Persia (632–651) brought the successors of Mohammed to the Indus, and they subsequently acquired a temporary hold of some parts of India, as Sind, which they conquered in 710 and lost in 750. The foundation of a more durable Mohammedan empire in India was laid some centuries later. The Kingdom of Ghazna, in Afghanistan, founded, according to Ferishta, by Alpetegin, an ex-governor of Khorassan, in 962, was declared independent by Mahmud in 999. This monarch, of whom as many as 12 expeditions into India are recorded, penetrated in one direction beyond the Jamna; in another he occupied Gujarat and captured Somnauth. He annexed the territory of Lahore to his kingdom, and nominally extended his dominion to the Ganges on the west, and to Gujarat on the south. His last expedition was to Gujarat in 1024. About the middle of the 12th century the Kingdom of Ghazna was divided, and Lahore became the capital of the Indian portion. The Ghaznavid Kingdom of India was overthrown in 1186 by Mohammed Ghori. On his assassination in 1206 Kutb-u-din, his governor in India, established the Afghan or Pathan dynasty at Delhi, and conquered Behar and Bengal. His successor Altamsh conquered Sind (1225), and completed the subjugation of Hindustan. About this time Genghis Khan overthrew the western empire of Ghazna, and founded a great Mongolian empire, which began to extend eastward, and came into collision with the monarchs of Delhi while these were still pushing their conquests to the south and east of India. The Delhi kingdom was, moreover, exposed to frequent commotions, both from the revolts of its own rajahs and from the predatory excursions of the hill tribes. A revolt of the rajahs was suppressed in 1250, and in 1265, after an extensive slaughter of the predatory tribes, a line of forts was constructed to check their incursions. But though frequently defeated the Mongols continued their incursions into northern India. In 1240 they reached Lahore, in 1244 they invaded Bengal; the Punjab was subject to frequent invasions; in 1298 they were defeated at Delhi. A new dynasty, the Khilgi dynasty, arose under the usurper Jelal-u-din in 1288, which was succeeded by a fresh dynasty in 1321, the house of Toghlak. The invasions of the Mongols still continued with greater or less success. During the reign of the last Toghlak king the celebrated Tamerlane invaded India at the head of a great host, took and sacked Delhi in 1398, leaving behind him his deputy Khizr Khan, who now assumed the government. A period of anarchy ensued, which terminated in the conquest of India by the Mogul emperors. Ibrahim, the last of the dynasty of Lo 'i, the third in order from that of Toghlak, was defeated in 1526 by Baber, who established the Mogul dynasty in Hindustan. His grandson Akbar succeeded his father at the age of 14 (1556), and during a long reign of about 50 years, terminating in 1605, subdued nearly the whole of India, which, by introducing religious toleration, he succeeded in consolidating into an empire. At the death of Akbar his empire was divided into 15 subahs or vice-royalties, which indicate its extent, namely, Allahabad, Agra, Oudh, Ajmir, Gujarat, Behar, Bengal, Delhi, Cabul, Lahore, Multan, Malwa, Berar, Khandesh, Ahmadnagar. His son Selim succeeded him under the title of Jehanghir. The Portuguese, as will be seen in another section, had already established their territorial dominion in India. In 1615, an English ambassador appeared for the first time at the court of the Mogul emperor in Hindustan. Jehanghir died in 1623, and was succeeded by his son Shah Jehan, who had disturbed his father's reign by rebellions, and during his own reign the country was filled with civil wars. He quarreled with the Portuguese, and expelled them from their settlement at Hugli. During his reign the Mahrattas or Marathas, under their chief Sivaji, began to be an important power in the Deccan. Shah Jehan was deposed in 1658 by his youngest son Aurengzebe, who also murdered his brothers. His reign was passed amid continual contests, both for extending his dominion, and subduing the revolts of the numerous peoples under his sway, both within the limits of India and beyond the Indus. He made war successfully with the Afghans, the Rajputana tribes, and the rising power of the Mahrattas. The Sikhs, a Hindu sect which had been persecuted by the Mohammedans, formed a religious and military commonwealth in the Punjab in 1675. Aurengzebe died at Ahmadnagar, in the Deccan, in 1707. On his death the Mogul Empire began to decline. The succession was disputed by his four sons. Bahadur Shah, who succeeded, died in 1712, and was succeeded by his son Jehundar Shah, who, in the following year, was put to death by Farokshir, a great-grandson of Aurengzebe, who usurped the crown. He was deposed and put to death in 1718 by Hosen Ali. Mohammed Shah, grandson of Bahadur, was raised to the throne in 1718. His reign was disturbed by the insubordinate spirit of his viceroys, and through the defection of one of them, the Mahrattas succeeded in subduing the Deccan. In revenge for an insult Nadir Shah of Persia invaded Hindustan in 1738, took possession of Delhi, and gave it up to be sacked and plundered by his soldiers. The country west of the Indus was ceded to Nadir Shah in 1739. Mohammed died in 1748, and was succeeded by his son Nadir Shah. The empire was now tending to dissolution. The new emperor called in the Mahrattas in 1751 to aid him against the Rohillas, who, in 1749, had defeated the last imperial army ever called into existence. The various states were seized by the former viceroys or by independent chiefs. The Mahrattas, now the most powerful people of India, possessed, besides the Deccan, part of Malwa, and the greater part of Gujarat, Berar and Orissa. The whole empire was at this time in extreme agitation and disorder, every government fearing the attacks and intrigues of its neighbors. Ahmed Shah was deposed in 1754 by Ghazi-u-din, a former vizier of the empire, who set up Alamgir II. In 1757 Delhi was captured by the Afghans, against whom Ghazi-u-din called in the Mahrattas. In 1759 the vizier assassinated the emperor. His successor, Shah Alum, without the shadow of power, escaped from Delhi, and finally took refuge with the British. The rival powers of the Afghans and the Mahrattas, which had been brought into collision by the feebleness of the empire, now engaged in a

fierce struggle for the mastery over its ruins. This terminated at the decisive battle of Paniput, fought 6 Jan. 1761, in the complete overthrow of the Mahrattas. The victor, Ahmed Shah, recognized the grandson of Alamgir as emperor by the title of Shah Alum II; but the empire was now only a shadow, and the native states, which had divided its powers, were destined soon to give way to the superior European commercial organizations which the pursuit of gain had brought to their shores. Henceforth the history of India follows the course of these European colonies, until it is merged in the Indian Empire of Great Britain.

The doubling of the Cape of Good Hope opened up the way by sea to India, and led the Portuguese to the possession of a kingdom in Asia. A few years after Vasco da Gama had landed on the coast of India they were already the most favored merchants upon the whole coast, and in spite of the active jealousy of the Mohammedans, who had hitherto monopolized the lucrative commerce of India, they formed settlements, and made commercial treaties with some Indian princes, in which the latter acknowledged the king of Portugal for their lord. By 1542 the Portuguese ruled from the Arabian to the Persian Gulf; the few ports and islands on the coasts of Persia and India fell into their power; they possessed the Malabar coast ports, and had settlements on the coast of Coromandel and the Bay of Bengal; Ceylon was tributary to them; they had factories in China; and the ports of Japan, to which a tempest had shown them the way, were open to their merchant ships. For 60 years they carried on their lucrative commerce without any considerable rivals. Portugal owed this power to a few able men, among others Francis of Almeida, and Alfonso de Albuquerque. But the successors of the men were not endowed with the same talents, and a revolting abuse of power excited the resistance of the natives, who became united by the sight of their common danger. The union of Portugal with Spain, under Philip II, in 1580, decided the fall of their commercial power in India. The Portuguese, satisfied with bringing the commerce of India to Lisbon, had allowed the Dutch to become the carriers between that port and the markets of Europe. But Philip II closed the harbor of the Portuguese capital to the Dutch ships on account of the revolt of the united provinces, and thus obliged that enterprising people to go to the sources of this commerce. Cornelius Houtmann in 1595 was sent with four ships to India to explore the coasts and gain information concerning the inhabitants and the commercial relations in that region. He returned with favorable accounts, for in this very first voyage treaties of commerce were made with the princes of the island of Java. The hatred of the natives against the Portuguese, who had at times landed here, assisted in the accomplishment of the enterprise. After the Dutch East India Company had formed settlements at Java and upon other points, and had made commercial treaties with several princes of Bengal, there began the long struggle with the rival Portuguese. The stronger and better-served navy of the Dutch enabled them to take one place after another from the Portuguese. In 1607 the latter were stripped by their victorious rivals of the Moluccas; in 1641 of Malacca; in 1658 of Ceylon; in 1660 of Celebes, where the Portuguese had settled after the loss of the Moluccas, to retain, by smuggling, some part of the spice trade; and after 1663 the most important places on the coast of Malabar, where they had longest maintained themselves, fell into the power of the Dutch. The Dutch made Batavia the capital of their eastern dominions. Their power in India began to decline from the time of their wars with Louis XIV. The English began to form commercial settlements in India about the same time as the Dutch. A settlement was formed at Surat in 1613, which became the chief station of the company on the west coast in 1615, and in 1657 the seat of a presidency. A grant of a small territory around Madras was received from the Rajah of Vijianagar in 1639, on which was erected the fort of Saint George. Madras became a presidency in 1654, and till the rise of Calcutta commanded the company's possessions in Bengal. Calcutta, the third presidency, and ultimately the seat of government in India, was settled in 1690, and became a presidency in 1707. The English acted as agents for the Rajahs and Nabobs. The English had to defend themselves against the Mahrattas in Surat in 1664, and early came into collision with the Portuguese and Dutch in the Indian seas. It was, however, the struggle with the French, who followed them, and who had acquired considerable territorial possessions in India, and the alliances of both parties with the native princes, coinciding with the decay of the Mogul Empire, which brought about that long succession of almost unbroken successes by which this great empire was established. The claims of rival candidates for the governments of the Deccan and the Carnatic brought the two parties into collision at various points, and after a succession of maneuvers Dupleix, the French commander, succeeded in compelling the English to take refuge in Trichinopoly. Here Clive, who had already distinguished himself in an unsuccessful attack upon Pondicherry, proposed to carry the war into the enemy's country. In 1751 he besieged and took Arcot, Tinnevelly, Conjeveram and Arani. On his return to Fort Saint David he was despatched by Major Lawrence on another expedition, which he again conducted successfully. Lawrence at the same time gained other successes against the French and their allies. These successes led to the Treaty of Pondicherry in December 1754, in which the French and English agreed to divide their territorial possessions on a footing of equality, and abstain from interference in native affairs. This treaty procured for the English the cession from the French of the Four Circars; nevertheless, they treated it as a dead letter, and immediately began to reduce Madura and Tinnevelly. The French, after vainly remonstrating, followed their example in disregarding the treaty. About this time important events took place in Bengal. Suraj-ud-Dowla, nabob of Bengal, in 1756 besieged Calcutta with a large army, when it was evacuated so suddenly by the English that a considerable part of the garrison was left behind. These had no alternative but to surrender (20 June 1756). Clive, who was sent from Madras with an armament to Bengal, recovered Calcutta on 2 Jan. 1757. War had again broken out between France and England, but the French refused

the alliance of Suraj-ud-Dowla, and maintained their neutrality. Suraj again invested Calcutta, but Clive, though he failed in a night attack, inspired him with so much respect for his means of resistance that he restored the English factories and made peace. Regardless of the benefit he had received from the neutrality of the French, Clive, in spite of the opposition of the nabob, determined to attack their settlement at Chandernagor, which he succeeded in taking. The nabob supported the French till he was attacked by the Afghans, when he became desirous of peace with the English. Clive, however, had determined to dethrone him and replace him by Mir Jaffier, his aunt's husband. In the battle of Plassey, 23 June 1757, the nabob was overthrown, and afterward assassinated by the son of his rival. Mir Jaffier bound himself to pay for his elevation a sum of over £2,500,000 sterling. This plunder was partitioned among the company and the company's servants, with the exception of a small share assigned to the native allies.

While the English in the Carnatic were engaged as collectors for Mohammed Ali in reducing the districts of Madura and Tinnevelly, the French recommenced hostilities. An attack upon Trichinopoly failed (May 1757), but Bussy reduced Vizagapatam, and established the French superiority throughout the Deccan. Count de Lally, who had arrived with a formidable armament in April 1757, besieged and took fort Saint David, 1 June 1758. He afterward besieged Tanjore and Arcot, the latter of which he took. The want of funds, which crippled his operations, compelled him to engage with inadequate forces in the siege of Madras, which, after lasting two months, entirely failed in February 1759. The English took Conjeveram, to which the French retired, by assault. In the following campaign the French, after some successes, were totally defeated by Colonel Coote near Wandewash on 22 Jan. 1760. Their power was now completely broken, their fortresses one after another fell into the hands of the English, and the English fleet, which had the command of the seas, co-operated in the reduction of those on the coast. Pondicherry, their last stronghold, surrendered on 15 Jan. 1765. The English had now established themselves, as a formidable if not altogether a ruling power, both in west and south India; but in both they committed the mistake of greatly over-estimating the resources of the country, and their rapacity and extortion, though they ultimately led to the extension of their power, were the cause of serious and protracted troubles. Mir Jaffier was deposed in favor of his son-in-law, Mir Cossim, who rebelled against English extortions, but, notwithstanding his skilful and vigorous preparations for a war he had anticipated, was worsted in successive engagements, particularly at Gheriah, 2 Aug. 1763, and forced to flee. In revenge he massacred his English prisoners. Sujah Dowlah, the nabob of Oudh, who received him, was defeated and deprived of his dominions, with the exception of Corah and Allahabad, which were given to the Mogul emperor, who formally invested the company with the dewanee or collectorship of revenues and virtual sovereignty of Bengal, Bahar and Orissa, by a firman dated 12 Aug. 1765. The English came to terms with Nizam Ali, subahdar of the Deccan, who opposed their occupation of them, by agreeing to pay him a rent for the territory, and assist him with their forces, but this agreement brought them in 1766 into collision with Hyder Ali, the powerful sovereign of Mysore. Nizam Ali afterward joined Hyder against the English, and both invaded the Carnatic, and, in spite of several defeats, laid waste the country to the gates of Madras. Finally, Nizam Ali deserted Hyder, and the latter concluded a treaty with the English, April 1769, by which their conquests were mutually to be restored.

Notwithstanding the protests and prohibitions of the directors, the administration of the company's affairs left much to be desired even during Clive's governorship, and during the administration of Verelst, who succeeded Clive in 1767, the company's affairs were in extreme embarrassment. Parliament took advantage of the discontent and clamor raised against the company's servants, and in 1773 remodeled the constitution of the company, and appointed Warren Hastings (q.v.) governor-general of India, with a salary of $125,000, and a council of four members, each of whom had $50,000.

His administration was marked by firmness and resourcefulness in upholding British interests, and also by his unscrupulous methods in raising money to carry out his projects. In 1778 war again broke out between France and England. The English captured Pondicherry and Mahé, the last port of the French on the Malabar coast. This place was considered by Hyder Ali as one of his dependencies. In revenge for its capture he seized the passes of the Eastern Ghâts, invaded the Carnatic with an army of 120,000 men and laid waste the country. Sir Eyre Coote was sent into the Carnatic to conduct the war against him. Hyder Ali died in 1782, but the war was continued with his son Tippoo Saib, till 11 March 1784, when it was concluded by a treaty of mutual restitution. In 1784 Pitt's India Bill was passed. In 1786 Lord Cornwallis succeeded Hastings as governor-general. Cornwallis made various administrative reforms for the relief of the people from former exactions, but Tippoo Saib diverted his attention from these peaceful measures by attacking the Rajah of Travancor, now an ally of the British. Having made an alliance with the Mahrattas and the Nizam, Cornwallis invaded Mysore, besieged Tippoo in his capital, compelled him on 9 March 1792 to conclude a treaty, by which he ceded half his territory and undertook to pay the expenses of the war. On the death of Mohammed Ali in 1795, Lord Hobart, governor of Madras, determined to assume the government of the Carnatic, but the plan was opposed by the supreme government and was not carried out. In 1798, Lord Mornington arrived in India as governor-general, when Tippoo Saib was making arrangements to renew his enterprises against the British and soliciting the alliance of France and of Cabul. Early in 1799, Lord Mornington invaded Mysore. On 4 May, he stormed Seringapatam. Tippoo was killed in defending his capital, and Mysore was divided among the British, the Mahrattas and the Nizam. Some time before this (1775) Oudh had agreed to receive and subsidize auxiliary troops for the defense of their territory, and the fortress of Allahabad was ceded to the British, who undertook to defend Oudh against all enemies. Subsequently

in 1801 the subsidy was commuted for the cession of southern Doab, Allahabad, and other territories. During the war with Tippoo, Lord Mornington, whose policy was to induce the native powers to accept British protection and mediation in their disputes, endeavored to induce his allies the Mahrattas and Nizam Ali to come under similar arrangements. The Nizam in 1798 agreed to dismiss his French troops and receive British auxiliaries. The Peshwa, the nominal head of the Mahratta Confederacy, forced by the contentions of the chiefs Holkar and Scindia, accepted the policy of the governor-general. Under the Treaty of Bassein, signed 31 Dec. 1802, Sir Arthur Wellesley restored the Peshwa, driven from his capital by Holkar. Scindia and the Rajah of Berar now entered into an alliance against the British. After a campaign in 1803 distinguished by the successes of Generals Wellesley and Lake, the former defeating the allies at Assaye, 23 September, the latter at Laswaree, 1 November, Scindia was compelled to make peace. He ceded to the British, Baroach, Ahmadnagar, and the forts in the Doab (29 December); the Rajah of Berar ceded Cuttack (17 December). Scindia, thus weakened, accepted the British alliance, and received an auxiliary force to defend him against Holkar, 27 Feb. 1804. A war with Holkar immediately followed, which the skill of that chief in predatory warfare enabled him to sustain with some dexterity, and in 1805 he was joined by Scindia, but the British arms finally prevailed and he was forced to flee. The Marquis of Cornwallis succeeded Wellesley on 30 July 1805. He disapproved of the ensnaring alliances into which the former statesmen had drawn the native powers, and although he died before being able to carry out his views (5 Oct. 1805), Sir George Barlow, who succeeded him, adopted his policy. New treaties were made with Scindia, 23 November, and Holkar, 24 December, restoring their territories and their independence. The new policy was even carried so far as to abandon the petty princes who had trusted to the British alliance. Lord Minto succeeded to the governor-generalship in 1807. During his administration the chief enterprises of the English were directed against the insular possessions of the French and Dutch in the Indian seas. The Moluccas, Java and other islands were taken; many of which were restored at the peace. Some disturbances took place during this period at Travancore, and among the British troops at Madras and elsewhere, which threatened at one time serious consequences. Travancore and Cochin were placed under British management. The Earl of Moira (Marquis of Hastings) succeeded to the governor-generalship in 1813. In 1814 a war broke out with Nepal, which was at first attended with some serious repulses, but was brought to a successful close by Sir D. Ochterlony in 1815, and resulted in the cession of Kumaon. Hastings was also called upon to suppress the Pindaris predatory bands of the former troops of Holkar and Scindia; and the Peshwa of Indore rebelling against a treaty his capital was seized, he himself deposed, and the Mahratta Confederacy dissolved. His ally the Rajah of Nâgpur, Scindia, who submitted, and Holkar, who was defeated, were compelled to accept alliances virtually placing them under British protection. This pacification was completed in 1818, and greatly improved the revenues of the districts affected by it. The Marquis of Hastings was succeeded in 1823 by Lord Amherst, under whom the first Burmese War was concluded in 1826 by a treaty ceding to the British the Aracan and Tenasserim provinces together with a large pecuniary indemnity. During the governor-generalship of Lord William Bentinck (1828–35) various administrative reforms were effected, but no great political events took place. Lord Auckland assumed the governor-generalship in 1836. The Afghan War broke out in 1838, in consequence of long and complicated intrigues arising from the advance of Russia in the East, and the mutual jealousy of that power and Great Britain. War was declared on 1 October, the object of the British was to dethrone Dost Mohammed and restore Shah Sujah, a former ruler. It was at first attended by great disasters, particularly the famous massacre of the Khoord Cabul Pass. It was terminated in 1842, under the governor-generalship of Lord Ellenborough, by the evacuation of Afghanistan by the British, after they had relieved their captives and vindicated the superiority of their arms by the capture of Cabul. Sind was annexed to British India after a war conducted by Sir Charles Napier in 1843. After a brief war, arising out of a disputed succession, the dominions of Scindia lay at the mercy of the British, and were disposed of by a treaty dictated by the governor-general at Gwalior in January 1844. While he was thus engaged Lord Ellenborough was recalled and superseded by Sir Henry Hardinge (May 1844), who was soon engaged in one of the most formidable wars the British had yet had to encounter in India. The Sikhs, a politico-religious sect already mentioned, had, under their leader, Runjeet Singh, conquered the Punjab about the beginning of the century. Runjeet Singh, who had always maintained friendly relations with the British, died in 1839, and the government fell into a chaotic state; the army, being without a head, began to commit disorders and threaten encroachments on the British territory. In December 1845 the Sikh army crossed the Sutlej in great force, and in the short war which followed the Sikhs were defeated by Sir Hugh Gough and Sir Henry Hardinge at Moodkee, Ferozeshah, Aliwal and Sobraon. Peace was made at Lahore, by the surrender of the Sikh territories on the left of the Sutlej, and between the Sutlej and the Bias (Jalindar Doab), and the payment of an indemnity. During the governor-generalship of the Marquis Dalhousie, 1848–56, a new war broke out with the Sikhs, and after their final defeat by General Gough at Gujarat, 21 Feb. 1849, the Punjab was annexed to the British dominions. This was immediately followed by the second Burmese War, ending in the annexation of Pegu, 20 June 1853. Sattari, Jhansi, Nâgpur and Oudh were, on the failure of the native succession, also annexed to the British possessions, 1852–56. During Lord Dalhousie's administration the extensive scheme of Indian railways and telegraphs was planned and inaugurated, the Ganges Canal opened, and the Punjab Canal began. His last important act as governor-general was the annexation of Oudh, 7 Feb. 1856. The annexation of Oudh, and other provinces, combined with a general feeling of unrest brought about the mutiny of the native army. (See INDIAN MUTINY). He

was succeeded by his friend Lord Canning; in less than a year after the arrival of the new governor-general, a mutiny of the native troops took place at Meerut, on Sunday afternoon, 10 May 1857. The main incidents of the Indian mutiny are the massacre at Cawnpur; the defense of Lucknow, under Sir Henry Lawrence; the taking of Lucknow, by General Havelock; and the siege of Delhi, 14 Sept. 1858. The mutiny sealed the fate of the East India Company, after a rule of more than 250 years, and brought about the transfer of the country to the direct authority of the Queen of England. The Royal Proclamation was read at a grand durbar at Allahabad, 1 Nov. 1858.

The subsequent history has been one of steady advance and general prosperity under the rule of viceroys appointed by the British government.

1 LORD CANNING became the first viceroy of India. He left India in March 1862, and died shortly after his arrival in England.

2 THE EARL OF ELGIN, became viceroy in 1862, and died in India November 1863.

3 SIR JOHN LAWRENCE, afterward created Baron Lawrence, 1864–69. Reformed the finances. Bhutan war. Orissa Famine, 1866.

4 VISCOUNT MAYO, 1869–72. Received Amir Sher Ali Kehan of Kabul in great state at Umballa 1869. Assassinated by a convict in the Penal Settlement at Port Blair.

5 EARL OF NORTHBROOK, 1872–76. The Prince of Wales, later King Edward VII, visited India. A famine in Bengal. The Guikwar of Baroda deposed.

6 EARL OF LYTTON, 1876–80. Famine in South India. The invasion of Afghanistan. The proclamation of the Queen of England, as Kaisar-i-Hind, or Empress of India, 1 January 1877.

7 MARQUESS OF RIPON, 1880–84. Extension of municipal government. Various reforms in favor of the natives.

8 MARQUESS OF DUFFERIN, 1884–88. Third Burmese War. The annexation of Upper Burma with the Shan States. The "Scientific Frontier" of India defined and strengthened.

9 MARQUESS OF LANSDOWNE, 1888–93. The strengthening of the army and the defences of India. Reform in currency, closing the free coinage of silver. Reconstruction of the provinces of India.

10 EARL OF ELGIN, 1894–98, son of a former viceroy. British control of the northwest frontier of India strengthened. Earthquake in Anam 1897. Cholera, plague, and famine 1895. Frontier War. Celebration of the Queen-Empress's Diamond Jubilee.

11 VISCOUNT CURZON, 1899–1905. Dispatched 8,000 British troops to S. Africa 1899. About 20,000 sent to China 1900. One of the worst Indian famines on record. A period of reform and reconstruction. King Edward proclaimed Emperor of Delhi 1 Jan. 1903. Political mission to Tibet 1904. Seven earthquakes April 1905. Resigned August 1905.

12 EARL OF MINTO, arrived in India November 1905. A descendant of a former Governor-General of India. Partition of Bengal Province 1905. Visit of Amir Habib Ullah Khan of Afghanistan January 1907. The New Councils act was passed giving the natives a much larger share in the government of the country than they ever had before.

13 LORD HARDINGE arrived in 1910. He instituted several new reforms. King Edward died and George V was proclaimed King in 1911. Delhi Durbar held in 1911 at which King George and Queen Mary were present. The capital was transferred from Calcutta to Delhi where 22 Dec. 1912, Lord Hardinge made his vice-regal entry.

14 LORD CHELMSFORD arrived as Viceroy, March 1916.

15 LORD READING succeeded as Viceroy, 1 April 1921.

The Nationalist Movement.— Supplementing what has already been written under *Land Tenure and Revenue*, is this quotation from a report by Lord Lawrence, Viceroy from 1864–69:

"The people of India are capable of administering their own affairs and the municipal feeling is deeply rooted in them. The village communities, each of which is a little republic, are the most abiding of Indian institutions."

This statement furnishes the keynote of a modern Nationalist movement which strongly suggests the similar movement in Ireland. Insisting that the Indian national spirit has never died but is steadily growing, the desirability, the justice, the necessity of Indian self-government, is persistently advocated by different types of Nationalists — Extremists who do not recognize the British government, Nihilists, Religious Extremists, Mother Worshippers, Vedantists and Advocates of Organized Rebellion, the Hardayalists, followers of Har Dayal. All these factions have different opinions as to religion, politics and economics, and while most of them would be glad to have self-government established within the empire in the near future, there is practical unanimity among them as to the goal most to be desired for India — complete independence. The organized Nationalist movement began to make its power felt when on 16 Oct. 1905 the old province of Bengal was partitioned by Lord Curzon. The years 1905, 1906 and 1907 were years of passive resistance, during which anti-British propaganda was carried on by means of the press and platform, but force was not used. During this time many Nationalist editors and publishers were sent to prison without any diminution of the campaign. In 1907 the Nationalist party split into two sections, one favoring force and the other passive resistance. The first shot was fired in December 1907, and the first bomb thrown in 1908. Rigorous action on the part of the authorities kept the disaffection under, but the propaganda continued and the lives of several high officials were attempted. In 1911 the king modified the partition of Bengal and ordered the transfer of the capital to Delhi, an action regarded as a triumph of the Nationalist agitation. On 22 Dec. 1912 a bomb was thrown at Lord Hardinge, the Viceroy, who was wounded, and an attendant killed, when he made his first state entrance into Delhi, the new capital. The revolutionaries still continue active, under Mohandas Karamchand Gandhi, who preaches the policy of non-resistance, but insists at the same time on non-co-operation with the English in India, hoping to drive them out by boycotting.

INDIA, Art and Architecture of. Although considerable light has been thrown on

Indian art and architecture, a great part of the knowledge that exists at present is vitiated by the fact of the subject having been approached from a very unsympathetic point of view. The fundamental of Indian art is symbolism and foreign students and critics have ignored this fact altogether. As a matter of fact, efforts have been almost altogether directed toward disproving the fabulous antiquity claimed for Indian art by tradition. It is only in very recent times that sympathetic critics have attempted to treat the subject from the right point of view. There is no doubt that the oral traditions in India have built up an absurd halo about the age of the temples; but, to a student of art, age must be a secondary consideration.

Twenty centuries of internecine warfare, the sweeping of the country by foreign hordes, and the several conquests, have naturally contributed to reduce all vestige of art to buildings that cannot be easily destroyed. We have very few examples of the development attained in comparatively ancient periods in the country. Of ancient paintings, we have only a few frescoes in the cave temples of Ajanta, Karli and Ellora. The literature abounds with descriptions of magnificent paintings, carved works in wood and ivory and all the paraphernalia of artistic expression. Ancient Indian history shows that there were cities which could well vie with the magnificence of modern cities, and possessing all the expressions of artistic luxury.

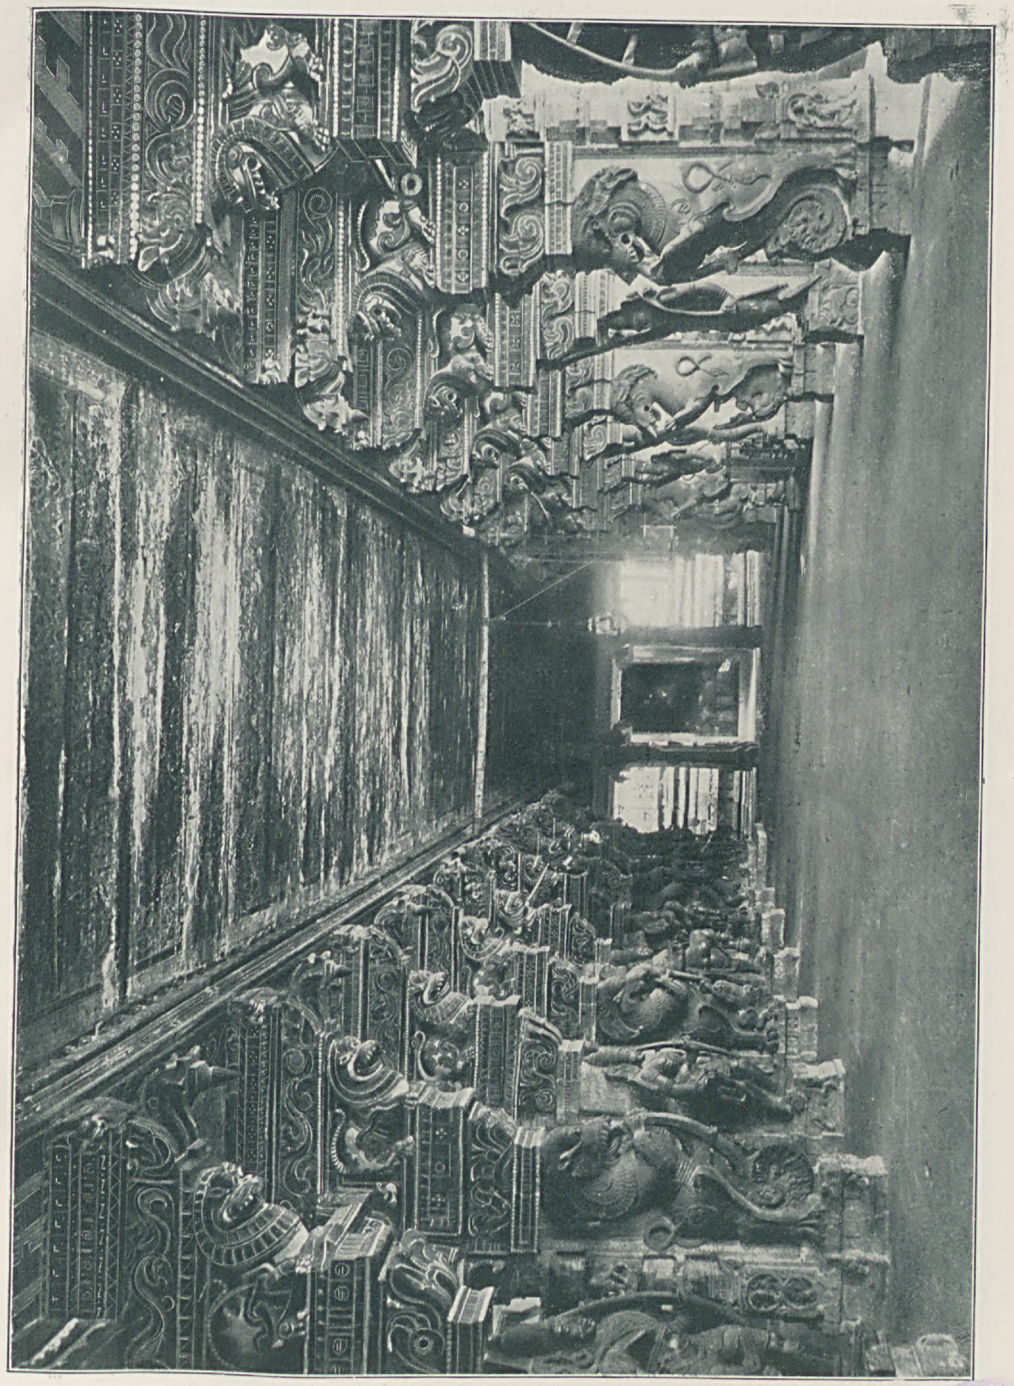
We must judge of ancient Indian art by the temples — the mammoth structures that have existed for centuries. Whether these temples existed before the Christian era, or whether they owe anything at all to ancient Greek, Persian or Roman, are points not worth discussing. All that we know is that the inspiration is not foreign, and that the principles upon which they have been constructed were unknown to any other people. As a matter of fact, some of these structures that exist to-day are marvelous from an engineering point of view. The art of construction of some structures is not only lost, but baffles the engineering science of Europe and America.

There is general agreement on the point that Indian art owes its existence to Buddhism (q.v.). Ancient Brahminism had no temples, and the idea of any worship, but that of God in the form of nature was contrary to the interpretation then put on the Vedic texts. Buddhism was the religion preached by Buddha, hence there arose the necessity for deifying Buddha and worshipping him. The Brahmins fought such deification, and the erection of temples as being unholy. When the country turned away from Brahminism, and when more than 75 per cent of the people became Buddhists, under the powerful proselytizing influence of Asoka, the Brahmins retained their positions by practically incorporating the latter religion into their own. In that process, they took also the temples and developed them. Within a few centuries, they made sure that no Buddha was left in the temples and the images were renamed. In that manner, the worship of the countless Hindu deities became the vogue. To-day, there are at least a thousand mammoth temples in the country, while there are hundreds of thousands of small temples.

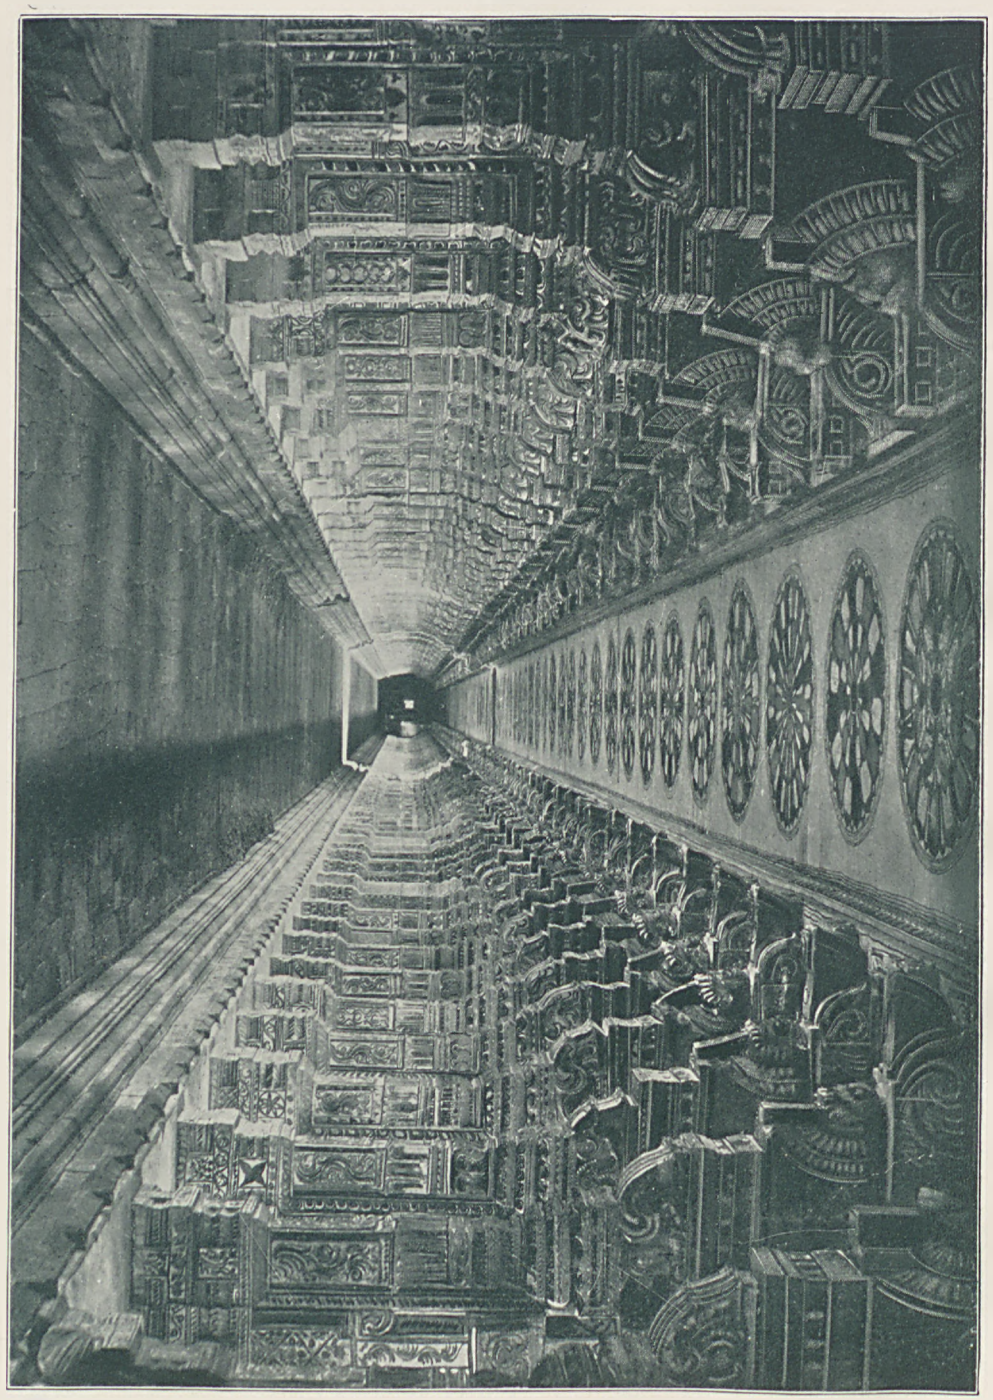
It would take too much space to detail the evolution of the temple. The Buddhists began with the construction of *topes*, in order to commemorate some event or to show that the spot was sacred. Most of these *topes* were constructed in the form of towers. The most notable of them being the Sanchi *tope*—the diameter of which is 106 feet. In the ancient Buddhistic period, there were besides *topes*, temples and monasteries. We have very few examples of monasteries at present, because with the downfall of Buddhism in India, the monastic order died out, and the buildings allowed to go to destruction. The earliest extant temples are the rock-cut cave temples — the date of whose construction is variously put from the 2d century B.C. to the 8th century A.D. There are three notable examples of these, at Karli, at Ellora and at Ajanta. The most wonderful of these are at Ellora. They are a series of caves sunken in the solid rock, extending a distance of three to four miles. The most notable caves are simply halls supported on massive piers, with level epistyles. The piers are richly carved with figures and friezes, and have a sort of cushion capitals and square abaci, and stand round forming a kind of atrium. The Indra court, the court dedicated to that deity, is open to the sky; within the court is a small shrine or temple in the solid rock are two halls — one larger than the other. The Visvakarma cave is a quadrangle open to the sky and surrounded by pillars. It leads into the atrium with three aisles and an apse. The most magnificent of all existing structures and significant as a purely Hindu work, is that part called the Kailas, which means literally, Heaven. The Kailas chambers and halls are sunk into the rock, and occupy a space 270 feet deep and 150 feet wide. The roofs are solid rock, supported by pillars, or rest on the walls or on the divisions of the assemblage of chambers. There is a porch, on each side of which, are two columns. This leads into the hall supported on 16 such columns, leading into a sort of adytum, around which is passage space and five chambers. The whole forms a temple with its usual appendages, exactly like one built on the ground, and around this is a wide open space with a colonnade or cloister encircling the whole. A great part of it is open to the sky for the sake of light and air but the work is entirely cut out of solid rock.

A distinctive architecture was that of the Jains. The Jain temple has a distinctiveness of its own, and the most famous example of an ancient temple is the Vimala-Sah on Mount Abu. The Jains, the Buddhists and later on, the Brahmins, all adopted the tower as the essential of the temple. The tower developed out of the dome, and the Indian dome has no boussoirs radiating from the centre, as in European architecture. The courses are all horizontal, and the domes are necessarily pointed in section, for they would not stand if circular. It requires no abutments and has no lateral thrust.

Although, the principles on which these temples have been reared are more or less the same, there is a marked distinction between the temples of southern India, and those of the north. At present, south India has more magnificent structures than the north. This is due probably to the fact that owing to the lateness of the Mohammedan incursion, the temple



Hall in Temple, Madura



The Great Hall in the Hindu Temple on the Island of Rameswaram

buildings were saved from destruction. The most famous of the southern temples are the temple at Tiravalur, the one at Tanjore and the one at Ramasvaram. The one at Ramasvaram has a hall 700 feet long and 150 feet wide, and it is so built that, although the light enters through one opening, there is not a dark corner in the whole of the building. The Tanjore temple has a tower 200 feet high, and resting on a base 83 feet square, and it is so constructed that it throws no shade. All the pillars of the southern temples, as well as the towers, are richly ornamented with carvings in relief. Among the most notable of northern buildings is the Black Pagoda of Kannaruc. The temples at Barolli and at Benares also need particular mention. The designs are great and the ornamentation profuse.

It is curious that, perhaps the most inspiring, and the greatest specimens of Indian art should be found outside of India. The Aughor Wat in Indo-China, and the temple at Mathura in Java are known to be the wonders of the world, and even those who have no appreciation of Indian art are inspired by the vastness of the structures, the greatness of the design, and the profuseness of ornamentation. These two structures cover very wide areas, and are now in ruins. They were reared by the Hindus when they ruled over those territories; and the temples fell into ruins when the Hindu conquerors had to leave those countries and come back to India.

The architecture of Siam and China, as well as that of Japan is wholly Indian. The Siamese *wats* and temples were reared by the Indian architects and resemble more closely the temples of India than those of Burma. The Chinese, who were great painters, never developed architecture, as their buildings were almost altogether in wood. The introduction of Buddhism into China was followed by the introduction of temple architecture, and the Chinese took to building with great avidity. The Japanese architecture has been purely employed in building temples to Buddha, and is still preeminently Indian.

It should not be imagined that there was only temple architecture in ancient India. There have been magnificent buildings, great from the point of view, both of size and height. Very few of them, however, are left, and such buildings as exist to-day have all been of a later date. The one notable building which is now in ruins is the University of Nalanda, near Patna, which flourished before the 11th century. The ruins are still to be seen, and it is stated that the university housed 20,000 students, Later Indian art of the best kind is to be seen only in southern India. The hall in the palace at Madura is an example of pure Indian architecture. In the north the Mohammedans brought with them the Saracenic art; and in course of time, the native Hindu and the Saracenic art blended well and produced a new type. The most noted example of this blending is the Taj Mahal (q.v.) said to be one of the nine wonders of the world. It is built of the purest marble on the banks of the River Jumna, and is described as a dream in marble. The Jumna Masjid in Delhi, and the several palaces that exist in different parts of the country also exhibit the result of the blending of the two styles. The basis of all architecture in India has, however, been the old Indian style, and the craftsmen have always been Hindus.

There are some buildings of distinctive Saracenic architecture, which are mostly mosques, or the places of worship of the Mohammedans, who form one-fifth of the population of India. The Indian mosques have, however, a very distinct touch of the Hindu craftsmen, especially with respect to capitals and the ornamentations. Saracenic architecture is distinctive for the elaboration of detail, and the Hindus took it and developed it. Possibly as the effect of Saracenic influence, later Hindu temples have almost a surfeit of detail work. In the temples of southern India, it is a common sight to see columns 15 feet high and 4 feet square, having as many as 10,000 figures carved in relief — every figure being distinctive. A column in the temple of Kumbakonum has the whole story of Ramayana carved in relief.

The secular buildings of later date are mostly halls and palaces. The Mohammedans revived the art of the dome, which had perished shortly after the Buddhistic period. A hall at Bijapur has a dome with a diameter of 100 feet, resting on columns without any support. There is not a piece of wood or steel in the whole structure, and it is constructed out of brick and mortar. The dome has been standing for at least 400 years, and is as good and strong as if it were built yesterday. Except in the wealth of detail, which varied with different centuries, the principles of India architecture have undergone no modification.

The art of statuary in India consists principally of casting the figures of the deities in bronze and similar alloys, and cutting the figures in stone. An elaborate science of statuary was built up, and at one time it appears to have been a serious study; but craftsmanship in India has always been a tradition, handed down from father to son. With the elaborate developments of the caste system, artistic knowledge became the possession of a body of people whose claim was based on birth. The technique of the art was considered a secret and kept in the family, as it were. As the religion allowed free play to the art of statuary, and as the kings and people of wealth considered building temples a passport to heaven, there was room for any number of images of deities. Later Hindu texts, especially the Puranas, gave room for the infinite play of fancy. Gods and goddesses in all shapes and forms were introduced, and imagination had the freest play. For instance, Siva, the favorite deity of the south, is represented with several hands and feet. Art critics of Europe have considered these statuaries — monstrosities; but recently the symbolism is being better understood. The Hindu considers his gods as being without human limitations, and the only way in which he could express this thought was by the creation of extraordinary attributes. Once this symbolism is understood, statuary in India will take a very high place in art. The making of alloys was known in India long before it was known in other parts of the world. The Iron Pillar at Delhi is a striking example of the engineering skill of ancient India.

Ancient works show that in ornamental work in gold and silver ancient Indians were adept. We have, however, not many examples of these at present, principally because the jewelry of the

temples in the north has been looted by the invaders. Even the tools appear to have been lost, although at present, some of the works done by gold and silver-smiths are in no way inferior in design and finish to those made in Europe or America.

For a number of centuries, painting in India has remained a lost art. The frescoes in the cave temples are recognized by art critics as representing a very high stage of development of the art of painting. There is a very long gap until we arrive at the Mohammedan period, during which time, noteworthy paintings saw the light. The special characteristic of Indian painting has been its magnificent detail, although some consider it a fault that a great number of subjects and figures should be crowded in a single canvas. It has also been customary to paint, on the walls of temples, the mythological stories. As a rule, these paintings have not been of high order.

Recent developments in painting have been very satisfactory. A distinctive school has sprung up in Bengal, and it shows traces of European influence. The most noteworthy painters are Nandalal Bose and Ganguly, who have also gone for their principal subjects to Hindu mythology. Most of the principal centres have native India artists, who are successfully developing a new school. Owing to the want of support, and the ignorance about Indian art, progress is very slow at present.

INDIA, Educational Progress in. The work of engrafting a system of modern education, essentially of an English standard, on the Indian Empire could not be hurried in view of the enormous labor involved and the vast population to be reached. The original Hindu system imposed upon every one of the higher caste the obligation to teach, primarily instruction was oral. Separate schools of law, of religion, astronomy, astrology and medicine came later. The villages were centres for schools in industrial art for which the Indian natives were adapted. The village boys were taught the vernacular and received ethical foundations in proverbs, stories and verses from the lips of the teacher. The Buddhists were no less exacting in their schools. It was the province of the Mohammedans as early as the 11th century, by their more democratic educational methods, universally established in the shadow of the mosque, to modify the rigid caste notions of India, their power being aided by the establishment of the Mogul Empire in the 16th century. With the rise of Christian influence in the 18th century and for a century later the missionary was the teacher. In 1813 on the renewal of the charter of the East India Company, an educational grant was included, although in 1780 and 1791 two private institutions were founded in Calcutta and Benares. A greater impetus was given to education in 1835 on Lord Macaulay's arrival, to promote the knowledge of European literature and science through the English language, and all agencies, missionary and private, municipal, provincial and governmental, were quickened in their activities. In the following decades, however, it was realized that the movement failed to prove popular — it seemed to be utilized by natives who desired government offices, but not by the masses of the people. Hence special commissions were appointed in 1882 and 1894 to improve the system from a practical point of view with the best results. While before the new century primary education reached the mere fringe of the population, in 1908 a marked advance was made. In 1907–08 the primary pupils in all the 10 provinces numbered 5,708,138, a 22 per cent increase over the previous year, and similar growth was noticed in every grade from the highest to the lowest.

The government's wisdom was shown in 1901 when an inspector-general of agriculture, with a staff of experts, was appointed. In 1903, a gift by Mr. Henry Phipps made possible the Imperial Agricultural College and Central Research Institute at Pusa in Berar. In 1905 the government set aside 20 lakhs of rupees ($644,000) was devoted to agricultural research and instruction. In a few years 60 experimental farm schools, in addition to demonstration plots, were established. Schools were begun and a state technical school, with scholars to be sent abroad for thorough instruction. A further evidence of progress in education is the national awakening toward the need of universities for Indian young men and women under their own auspices. Early in 1916, the University of Mysore was opened, the first of its kind in that part of India which belongs to the Indians and is ruled by them. It is significant that education is compulsory and free throughout this state, in which at latest reports with a population of six millions were 5,436 institutions, six colleges for men and one for women. The school pupils numbered 214,397, with 26,371 secondary and 934 collegiate. The new university is not an examining body but has a regular university lecture and tutorial system, with the Maharaja as chancellor. Instruction is given in the vernacular current in the state. The course is for three years. In February 1916 Lord Hardinge laid the foundation stone of the new Hindu University at Benares. No candidates are debarred on the score of religion. Instruction in the Hindu religion is compulsory for Hindus. The central Hindu College of Benares organized by Mrs. Annie Besant in 1898, was the nucleus of the new institution. Its aim is to promote the study of the Hindu Shastras and of Sanscrit literature generally as well as to advance technical, scientific and professional knowledge, with practical training, to encourage the industries and develop the resources of the country. Large sums were collected from all classes of educated Hindus, with the capitalized value of the recurring grants reaching £675,000. Women will be admitted. The Mohammedans at Hydera have founded a university called Nizamia after the Nizam or prince of that province, to teach the literature and science of Islam. The Mohammedans of Aligarh expect to have a charter for a university. Similar institutions are desired by the Indians in the Sikh states, in Cochin and Travonare. About the same time as the Mysore University was opened, the Indian Women's University began its work at Poona. Instruction is given in Marathi, with English as second language, and compulsory courses in domestic science. Besides the generous sums given for such colleges, recently large amounts have been donated by Indians to Calcutta University, to the Institute of Science at Bangalore, and elsewhere.

Since 1915–16 the public outlay for education doubled, amounting to £14,889,696 in 1919–20. In the same period, the number of schools rose from 189,000 to 202,981, and of pupils from 7,620,000 to 8,206,225, the girls showing a large increase. According to the census of India in 1921, 93.8 per cent of the population of British India were illiterate. The ruler of Baroda has made education free and compulsory and his example has been imitated by the Indian rulers of four states, with others to follow in due course. Consult Pandya, T. R., 'A Study of Education in Baroda' (India 1916); Education Supplement, London *Times*, 2 Jan. 1912, 7 March 1915; 'Progress of Education in India,'; *Quinquennial Review* (Calcutta Government Printing Office) 1881–82, et seq.; London *Contemporary Review*, January 1918. INDIA, Languages and Literature of. Although it is generally stated that more than a thousand languages are being spoken in India, and that the country is practically a babel of tongues, the principal vehicles of thought are less than 10. The languages now spoken in India are principally the dialects founded upon the corrupt Sanskrit, which is the parent of the Indo-European family of languages, and which has been a dead language for more than 25 centuries. Sanskrit bears the same relation to the Indian languages as Latin to modern European, with, however, certain important modifications. While Latin has furnished the roots and, to a certain extent, the grammar, Sanskrit in India to-day, is considered part and parcel of the spoken languages. Every word in Sanskrit can legitimately be used in any language, and the grammar is exclusive Sanskrit, except in southern India. Tamil, which is the language of southern India, is considered as an independent language spoken by the people whom the Aryans conquered; it has certain peculiarities, and a grammar which differs from the Sanskrit grammar. The conquest of the Aryans has been so complete as to metamorphose even Tamil and make it, for all practical purposes, a dialect of Sanskrit. The origin of the Indian languages must be directly attributed to Prakrit. Even in the time of Alexander the Great, Sanskrit had been superceded by Prakrit, which is the dialect of Sanskrit. This dialect took local color, as it were, in the different places and new languages were evolved. Besides the influence of Sanskrit, the incursion into India of vast foreign hordes left a very marked trace on the languages. Persian and Arabic, which were the languages of the Mohammedan conquerors, brought a large number of words and exercised an influence on literature.

The principal languages spoken in India may be divided into three distinct groups. The northern-Indian languages are the Hindi, spoken by 98,000,000 people; Bengali, spoken by 48,500,000; Punjabi, spoken by 16,000,000; and Rajasthani and Kashmiri, spoken by 10,000,000. Hindi is the language closest to the Prakrit and is spoken by as large a population as that of the United States. It is very rich in poetic literature and is growing in influence. Bengali is the language of Bengal, and next to Hindi has the closest affiliation with Prakrit. Up to a certain time, it was purely a spoken language, but during the last half-century, a great mass of literature has been built up — some of the works being recognized as the peers of the best in the world. The Punjabi, Rajasthani and Kashmari languages are, at present, more or less spoken languages and have yet to develop a literature. Punjabi has a great mixture of Persian and Arabic. Besides these languages, Hindustani or Urdu is spoken throughout northern India. This language is principally Hindi, mixed with Persian and Arabic and was the language of the Mohammedan conquerors — which is still favored by the British government because of its remaining the *lingue Franca*, in spite of the growth of English. The percentage of Persian and Arabic words in Hindustan is less than five, and for purposes of classification, it may be identified with Hindi. The central-Indian languages are the Marathi, spoken by 20,000,000 people; Gujarati, by 11,000,000; and Oriya, spoken by 10,000,000. Although both northern and southern languages are spoken in central India, the above three are distinctive. Marathi has the closest relation to Sanskrit next to Hindi, and Oriya has a great number of aboriginal words and extraneous influences. The southern-Indian languages are the Telegu, spoken by 23,500,000 people; Tamil, spoken by 18,000,000; Kanarese, spoken by 10,500,000 people; and Malayalam, spoken by 6,500,000 people. These four languages form a distinct group, in that, although dominated by Sanskritic influences, they have a non-Sanskritic base. Besides these principal tongues, there are a number of subsidiary languages like the Assamese, Shan, Sindhi and Pushtu, spoken by small bodies of people.

The golden age of Indian literature has, unfortunately been in the past, but all literature was then in Sanskrit. Up to the Renaissance in Europe, Latin was considered the only fit medium for literature; all the spoken languages were considered just mere mediums for ordinary communication. A similar sentiment prevailed in India, and even up to very recent times, Sanskrit was used by the learned to express their thoughts. Just as literature was practically confined to religion and philosophy up to the Renaissance, so Indian literature, up to recent times, has been mainly religious and philosophic. Long anterior to the rise of Buddhism in India, there was a great mass of secular literature. Dramatists like Kalidasa flourished during that period. Later on, the country was degenerating, until it became an easy prey to the Mohammedan conquest.

Beginning with the later years of the Moghuel rule, the Indian vernaculars began to be used as vehicles of thought, principally for religious and devotional purposes. Kabir-Das and Tulsi-Das were the pioneers in northern India, in making the vernacular respected as a literary language. Owing to the internecine strifes and the several wars which raged in the country for 200 years, until India came completely under British rule, there was no room for developments, and for all practical purposes, the hands of the clock were turned back. Only after the consolidation of the British Empire in India, the people began to see the possibilities of the development of the languages of their home. Indian society is so constituted that all attention was paid, and importance attached, to Sanskrit, as the language of their faith. The Brahmins, who have remained for over 30 years the custodians of the faith and literature of India, naturally had a much more than sentimental attachment to Sanskrit. It has been the practice to consider the spoken languages as corruptions and languages of convenience. The other classes of people simply follow in the wake of the Brahmin. Therefore, except on a few occasions, when the vernaculars revolted, as it were, against Sanskrit, no effort at all was made to improve them. The Brahmin, again, was fighting for his supremacy in the country. Any attack on Sanskrit he considered an attack on himself. Without meaning it, he has been the cause of the stagnation in the literary life of India. With the advent of British rule and long anterior to it, the Brahminical class was not purely sacerdotal. It devoted its attention to mundane pursuits and fought with other classes in the country for the amenities of life. Gradually it was devoting less and less attention to the study of Sanskrit. In the early decades of the 19th century, a very large percentage of the Brahmins all over the country were ignorant of Sanskrit. Instead of holding that the use of language of the home and intercourse in business as a vehicle of literary thought was something beneath their dignity, the Brahmins began to take real interest in the vernaculars. It has been the practice in India, that as soon as the Brahminical class takes interest in anything, the other classes are urged to pay attention to it. When a common interest was thus created, the rise and improvement of vernacular literature became just a matter of course.

It is not to be understood that during all the centuries intervening, there was no literature at all in the vernaculars. Sporadic attempts were made to create literatures, although the sum total of the efforts were very few works worthy of note, and most of them religious and devotional. The few that remain became, however, the classics; and the first successful effort was made in Bengal. Bengal was completely ruled by the British, while constant fighting was going on in other parts of the country. Moreover, the impact of Western civilization was greater in Bengal than in other parts of India. The reform movements, social and political, originated in that province, and the vernaculars were more freely used than before. The great reformer, Ram Mohun Roy, who was the founder of the new cult known as the Brahmo-Samaj, used the Bengali to disseminate his doctrines.

An event of great importance in the history of literature in India was the passing of the Education Act. When Lord Macaulay was fighting for the introduction of the English language, as a medium of education in the country, he did not for a moment imagine that the result would be what has happened to-day. H. H. Wilson, the great Sanskrit scholar, was all for Sanskrit as the medium of education; and his argument was sound in that he believed that such a step would be in accordance with tradition. The British government was, however, concerned with the supply of sufficient clerical aid to carry on the work of administration, and decided in favor of Lord Macaulay's proposal. For a time, the people of India, in their eagerness to assimilate the new knowledge, paid little or no attention to either Sanskrit or the vernaculars. When, however, education was advanced sufficiently to make the new scholars judges of the relative merits of English literature and their own ancient literatures, they found that they had been extraordinarily foolish in neglecting what they were entitled to call their own. The complete subjection and the improvement in the facilities of communication brought the different peoples in close touch with each other and made them feel that they had a common heritage which they were selling for a mess of pottage. A new nationalistic spirit began to prevail in the country and efforts were directed toward finding expression for such spirit. Sanskrit was unknown to a great mass of the people, and English was only known to a very small minority. Therefore, the only medium for expression, which could be at all effective, was rightly considered to be the vernaculars. The regeneration of the country had to be effected by the dissemination of as much of Western thought as possible. The leaders also found that they must work on the new lines, if there was to be any salvation for the country. The result was a flood of literature in the different vernacular languages, and credit should be given to Bengal for initiating the movement. The men and women, who were in the front of the movement, had a genuine English scholarship, and hence were able to give the people something which was novel. The chief writers of Bengal were Iswara Chandra Vidyasagar, Madhusudan Dutt and Bankim Chandra Chatterjee. Vidyasagar was the father of Bengali prose. Previous to his advent, there were no prose works of any length or merit in the whole of that province. He was a great reformer and flooded the country with literature of the rarest kind, which had an electrifying effect on the population. Few thought that the language could possess such prose works. Dutt was as unfortunate in life as Edgar Allen Poe, and his career was a romance of misery. He studied for the bar in England and had published some poems. They were considered by English critics as considerably above the average. Having been converted to Christianity when he was a youth, he was shunned by both the Hindoo and European communities. After a long period of domestic and financial unhappiness, he turned back to his old faith as a solace and began to write poems in his native tongue. When they appeared in print, Bengal was loathe to ascribe them to any modern writer and thought that it was the work of a genius or of an ancient sage. It is the irony of Fate that Madhusudan, the Christian, should

nave given the first rendition of Ramayana, in his native tongue. His work is a classic, and will remain a classic. Chatterjee was a government official and a sincere patriot. The two cannot go together in a country like India. He was fired by the enthusiasm of a visionary and was anxious to do something great. He wrote the first novels in the Bengali language, and he took for his guide Sir Walter Scott. He made the episodes of the fights for freedom, which his people waged against the inrushing hordes of Mohammedans, live. His descriptions and characterizations are almost unique, and such European writers as have studied his works in the original are unstinting in their praise. It is a curious fact, that a battle hymn from his «Durgesanandini,» called «Bande Mataram,» meaning, «Hail Motherland» has become the national song of India to-day. Thousands of men and women have been prosecuted and sentenced by the government, during the past few years, for just crying, «Bande Mataram.» After these pioneers, followed a host of young writers who have distinguished themselves in many ways; but latterly the political ferment in the country has led to greater attention being paid to newspaper work, rather than good literature. The two most famous writers of recent periods are, Romesh Chunder Dutt and Rabindranath Tagore. Dutt was a member of the Indian Civil Service, who occupied the highest position available for an Indian, under the British government. His work was mainly political, but his writings are considered good literature. Rabindranath Tagore has had international fame on account of his being awarded the Nobel Prize for literature in 1913.

There have been numerous writers in Hindi, Punjabhi, Gujarati and Marathi among northern Indian languages; but few have had an international reputation, with the exception of the late Behramji Malabari and Bal Gangadhar Tilak. Mr. Tilak has been more in the limelight as a politician, and will be remembered by his people as a master of Marathi prose. The activity, however, in these languages has been not even a small fraction of that in Bengali, and for various reasons has been frittered away in journalism. The vernacular journalism in Bombay is much more powerful and more modern than similar journalism in other parts of India.

The most interesting of the Indian languages is Tamil, which is the language of the southern half of Madras. It is closely affiliated with the three other languages spoken in the presidency, and being the language of the provincial metropolis is more influential than the rest. This language claims to be nearly as old as Sanskrit. It has a distinctive grammar, an alphabet which is found in no other language in the world, and a tradition which is older than that of any other modern Indian language. There is no doubt that the original Tamils were the inhabitants of the country, prior to the conquest by the Aryans. To-day, in spite of the fact of 25 centuries of intermingling, we find traces of people who are as distinct from the Aryans, as the negroes are from the white Americans. Culture and literature, however, is not in the hands of the original inhabitants. The language has, as it were, been taken up by the Aryans and remodeled. Although there are works which are undeniably known to be 15 to 16 centuries old, we have as yet no trace of Tamil literature without the influence and admixture of Sanskrit. The earliest works show Buddhistic influence. Evidently, Buddhism lasted longer in the south, than in the north, before it was driven out or incorporated into Brahminism. A fairly large number of classics of an early era is available in this language. Kural, Manimehalai and Silappathiharam are said to have existed anterior to the 8th century. Kambaramayanam, Naladiyar and Bharatam are at least 400 years old. Southern India was disturbed by the Mohammedan invasion only late in the day; and even after the Mohammedans came down south, life and literature were less molested than in the north. Since the British admistration, the same influences that have led to a Renaissance in Bengal, have also exerted a powerful influence in connection with Tamil. A number of young writers have produced works which can compare favorably with those of Europe and America.

A treatment of Indian literature will be very incomplete if sufficient attention is not paid to the press. The vernacular press in India is growing powerful every day, and as a rule contains much that is usually published in book form in Europe and the United States. The reason is obvious. The people, as a whole, are too poor to spend a great deal on books, and there is no regular market for literature, especially as the government places every obstacle in the path of the development of indigenous thought and writing. The papers published in the native languages in India are watched very carefully, and are the only means of support for those who choose a literary career. Therefore, they are on a much higher plane than the greater part of newspapers in any part of the world. There is, again, the satisfaction of making innovations and many of the subjects that are daily being discussed have never been treated in any manner in the past. These papers have a much wider circulation than their subscription lists disclose. Owing to the extraordinary apathy of the authorities in educating the people, and the very low percentage of literate people, the newspapers are usually read to the people. In a village, for instance, about 20 or 30 people will club together to buy a number of papers, and pay one man to read it to them. Just as people discuss affairs in the clubs of Europe and the United States, world politics is read and discussed in the village temple or the grove. In 1912, Bombay had 359 papers; Madras and the nearby states 256; Bengal, 258; the United Provinces, 223; and Punjab, 211,—all told 1,447 papers and magazines in the country. It is certainly a ridiculously low number for the extent of the country, but considering that it is an innovation, and that the vernacular press is fettered with all sorts of restrictions by the government, and the writers live in constant dread of being marched to jail any moment, it is indeed a matter for surprise, that so many should exist at all. Consult Grierson, 'Linguistic Survey of India' (Calcutta 1903 et seq.); Schmidt, P., 'Grundzüge einer Lautlehre der Mon-Khmer Sprachen' (Vienna 1906).

SRINIVAS R. WAGEL.

INDIA, Music of. Music was a science in India long before it was considered so in other

countries and the Hindu Scriptures are the first in recorded history to mention music as a science. The Rig Veda mentions musical instruments like the drum, the lute and the flute. The Sama Veda, as it was chanted in those ancient days, and as it is chanted even to-day, most conclusively proves that the science of vocal music was developed to a considerable extent. In ancient India the function of music was to assist in the performance of religious ceremonies. Even to-day most of the daily devotional duties of the Hindu are performed in chant or in rhythmical movements of the body. Strabo admits that the greater part of the science of Greek music owes its origin to India. The system of notation, which was perfected in India before 350 B.C., "passed through the Persians to Arabia and was from there introduced into European music by Guido d'Arrezzo at the beginning of the 11th century," states Montstuart Elphinstone, the English historian of India.

Hindu music is divided into seven chapters as follows: (1) Sur-Adhya treats of tones, semi-tones, etc.; (2) Rag-Adhya treats of tunes and melodies; (3) Taal-Adhya treats of time; (4) Ast-Adhya treats of musical instruments; (5) Nirt-Adhya treats of dancing; (6) Bhao-Adhya treats of actions and movements in rhythm with singing and dancing, and (7) Arth-Adhya treats of comprehension of tunes and times.

The scale of Hindu music has seven notes, just like Western music. They are Sa (shudja) which corresponds to the European note C; Ri (Rishaba) to D; Ga (Gandhara) to E; Ma (Madhyama) to F; Pa (Panchama) to G; Dha (Dhaivata) to A, and Ni (Nishada) to B. Each of these notes is considered to be presided over by a deity of the Hindu pantheon: Agni (god of fire), presides over Sa; Brahma (god of creation), over Ri; Saraswati (goddess of learning), over Ga; Mahadeva over Ma; Vishnu over Pa; Ganesh over Dha, and Surya over Ni.

Instead of the 12 tones and semi-tones of the European scale, the octave of Hindu music is divided into 22 quarter tones and thirds of a tone. That is the main reason why unaccustomed Western ears cannot, at first, appreciate Hindu music. It is so delicate that it does not sound like music at all; it sounds rather like a jumble of notes without the least æsthetic significance. "But," says a European critic, "the Hindu music has attained a theoretical precision yet unknown to Europe."

From the scale of 22 notes and quarter-notes the Hindu divides certain groups into Ragas. There are six Ragas, one for each season of the year. Sri Raga is for the winter, Vasanta for the spring, Bhairava for the summer, Megh for the rainy season, and Natanarayan for late autumn. The six Ragas are male, and there are 36 Raginis.

The Hindu masters of music have set aside different Ragas for different hours of the day. And it is improper to sing a song that is not suited to that hour of the day. As for example, Bhairava is sung from 4 A.M. to 8 A.M.; Megh from 12 noon to 4 P.M.; Dipak from 8 P.M. to midnight.

Again, the atmospheric conditions also go to decide on the Raga to be sung. When it rains the Hindu sings the Megh-Makar, and it makes you feel wet and hear the gentle raindrops fall. Near a fire or in an exceedingly hot hour of the day he would sing Dipak, a Raga that would make you feel a kind of burning sensation. According to Prof. Inayat Khan there are 400 main ryhthms in Hindu music.

Before singing the song itself the Hindu musician sings Alap. Alap is a kind of prelude to the song. There are no words to an Alap. It simply prepares the ground and creates an atmosphere for the ensuing song. Then, when the singer begins to sing, he is free to improvise as he wishes. He must, of course, conform to the general rule of the Raga, but he improvises according to the mood and the environment he is in, and the audience he is singing for. The master musician does not care much for the words of the song. He often sings one line, and then improvises it in a hundred different ways by repeating the same line a hundred different times. "Music," says Rabindranath Tagore, the Hindu poet and musician, "is not dependent on words. It is majestically grand in its own glory. . . . What words fail to convey to human mind, music does with perfect ease. Music begins when words end." This is certainly the spirit of Hindu music.

Unlike the music of the West, Hindu music is purely melodic. And yet the use of such words as Vadi (principal note), Samavadi (note subordinate to it) and Vivadi (discordant) in the Vedas plainly show that at least some of the rudimentary rules of harmony were understood by the musicians of the Vedic age. But it must be admitted, however, that Hindu music is essentially melodic. In other words, it is produced by successive sounding of single tones of different pitch, whereas the Western harmonic music is produced by the simultaneous sounding of single tones of different pitch. The melodic nature of Hindu music helps to lend itself easily to improvisation.

There are a thousand and one different kinds of musical instruments in India. For full particulars of which the reader should refer to the works of Raja Sourindra Mohon Tagore, and for a fuller account of Hindu music the reader must consult 'The Music of Hindusthan' by H. H. Fox-Strangways and 'The Introduction to the Study of Indian Music' by E. Clements.

INDIA INK, a black pigment, consisting commonly of lampblack, gelatine and water. The usual basis of India ink is a finely divided solid carbon, mixed with a size to hold it in suspension when the ink is prepared for use by mixing it with water, the depth of the shade being regulated by the quantity of water used in the mixing. This ink was originally made in China and Japan, where the ink is applied with a brush both for writing and drawing. In Europe and America it is now used chiefly for black-and-white drawings.

INDIA RUBBER, a colloidal substance obtained from the milky juice of several widely different plants, and otherwise known as caoutchouc or gum-elastic. The most important sources are: *Hevea Braziliensis* and *Castilloa elastica,* two trees native to South America but cultivated in many other sections; *Manihot Glaziovii, Ficus elastica,* several vines of genus *Landolphia,* and the Mexican guayule plant, *Parthenium argentatum.* Some of the properties of india rubber must have been known to the natives of America at a very early period, because balls made by the Haytians of the gum of a tree, bouncing better than the wind-balls of Castile, are mentioned by Herrera in his account of Columbus' second voyage. In a book published in 1615, Juan de Torquemada mentions the tree which yields it in Mexico, describes the mode of collecting the gum and states that it is made into shoes; also that the Spaniards use it for waxing their canvas cloaks to make them resist water. More exact information was furnished by M. de la Condamine in 1735. India rubber was at first known as Elastic Gum, and received its present name from the discovery (about 1770) of its use for rubbing out black-lead pencil marks, for which purpose it began to be imported into Britain in small quantities about the end of the 18th century. Its application to the manufacture of waterproof cloth first gave it commercial importance. About the same time a method was discovered of fabricating articles of various kinds by casting india rubber in molds. Until very recent years the india rubber of commerce was obtained chiefly from South America, but the larger part of the present market supply comes from the cultivated rubber plantations of British India and the Indian Archipelago, and a considerable and increasing quantity from the west coast of Africa and the Mauritius.

The sap as gathered from the rubber-yielding plants holds in suspension the globules of rubber, each being surrounded by a protective envelope of a proteid substance. In order to secure the coalescence, of these globules, various methods are employed in different localities and with different rubbers. The most common process is by exposing thin layers of sap to the heat and smoke of an open fire, but a method of chemical coagulation is employed in some localities following a condensation by a centrifugal treatment of the fresh sap. As it reaches the market, crude rubber is a very uncertain substance, containing from 15 to 50 per cent of impurities, much of which is simply dirt, as sand, bits of wood and clothing, leaves, plant fibres, etc. Other impurities which are normal to the sap are resins, sugars of several kinds, albumen, essential oils and a percentage of water, often very considerable. On some plantations of cultivated rubber the gum is carefully cleaned and washed before it is marketed, but generally the manufacturer's first operation is to wash the crude material. The lumps of raw rubber are first steeped in warm water until soft and then sliced into thin sections under water and run between deeply corrugated rolls, also under water until they are in thin wavy sheets resembling crepe. They are then dried in the air or in a vacuum chamber, being carefully protected from light which has a tendency to set up injurious chemical changes, especially oxidation. By the vacuum process the drying is completed in an hour and a half; by the air-drying method several days are required. As rubber is hygroscopic, the drying operation is one demanding skilled attention, for the vulcanizing of the rubber depends very largely upon the content of moisture.

Pure india rubber has the composition $C_{10}H_{16}$. It is insoluble in water, in the esters, and in the ethers — all of which, however, are readily absorbed by rubber, causing it to swell. The solvents used in the arts are turpentine, dipentine, petroleum spirit, carbon disulphide, benzene and chloroform. The solvent most frequently used is petroleum spirit, on account of its cheapness. As a matter of fact the usual phenomena of solution are not observed with rubber. The gum absorbs the solvent, becoming first a jelly, later assumes a viscous condition, and as more of the solvent is added it finally takes a freely liquid form. India rubber is highly distensible, and this property increases with the increase of temperature. If the degree of heat is carried to 200° F., the distension becomes permanent. Pure rubber is used to but a limited extent in the arts, but for all general purposes it is first vulcanized. Two grades of vulcanized rubber are prepared, one hard and horny in its texture, the other soft and elastic. In the case of the former the caoutchouc is mixed with about one third of its weight of sulphur and heated for several hours, the temperature finally rising to fully 300° F. For the soft kind of vulcanized rubber, on the other hand, a much smaller proportion of sulphur is required — viz., from 2½ to 10 per cent, and the heat to which it is subjected in the vulcanizing chamber is considerably less. Usually, too, with this latter kind, the articles are made before the rubber is heated. The sulphur is commonly added in the ground state, but sometimes the rubber is treated with some solution containing this element, such as the bisulphide of carbon.

Hard vulcanized rubber, termed vulcanite, and sometimes ebonite, is made into a great many small articles, such as combs, chains, bracelets, boxes, penholders, paper-knives, knife-handles, buttons, etc., as a substitute for materials like horn, bone, ivory and jet. Like these substances themselves, it is formed into various objects by molding, cutting, carving, polishing and other processes. Vast numbers of these articles are now sold. The black color of vulcanite ornaments has still a tendency to turn gray, but the brittleness which was a fault of combs made of it a few years ago has been overcome.

Manufactures from india rubber turned out from the factories of the United States in 1919 amounted to a value of $1,104,005,000. Of this total a value of $116,917,000 was in the form of boots and shoes. So great is the demand for india rubber, for use in manufacturing, that not only has the importation grown from 2,000,000 pounds in 1862 to about 800,000,000 pounds annually at the present period, but in addition to this the forests of the East Indies are called upon for several million pounds annually of a substitute for gutta-percha, known as "gutta-joolatong," while at the same time the highways and byways of Europe and other countries are ransacked for cast-off rubber manufactures from which the rubber is "reclaimed" and re-used in conjunction with the new rubber from the forests of Brazil, Africa and the East Indies.

The industry of importing and "reclaiming" india rubber for re-use in manufacturing is a

comparatively new one, and while it utilizes large quantities of worn-out rubber boots and shoes and other articles of this character from the scrap heaps of the United States, it has only taken in other parts of the world in recent years.

Importation.—In the fiscal year which ended 30 June 1923 the importation was 797,655,149 pounds valued at $169,108,499 as compared with 568,381,428 pounds valued at $86,751,219 imported in the fiscal year 1921–22. Of the 1922–23 importation, 547,799,814 pounds valued at $112,749,587 came direct from the British East Indies; 113,064,802 pounds valued at $23,159,117 from the Dutch East Indies; 30,771,572 pounds valued at $5,473,935 from Brazil; 1,574,697 pounds valued at $316,966 from Peru; 2,033,793 pounds valued at $470,642 from other South American countries, and 144,253 pounds valued at $25,822 from Mexico. Imports through the United Kingdom amounted to 75,700,650 pounds valued at $21,132,802 while imports through the Netherlands amounted to 10,821,152 pounds valued at $2,548,682. Imports of jelutong or pontianack amounted to 8,712,813 pounds valued at $702,486; imports of gutta-percha to 1,756,857 pounds valued at $979,860. Exports of rubber and rubber products in 1922–23 were valued at $37,964,988. Pneumatic casings for automobiles exported had a value of $17,544,649. Rubber shoes exported in 1922–23 totaled 832,739 pairs valued at $722,312. Rubber boots exported totaled 274,037 pairs valued at $717,970.

RICHARD FERRIS.

INDIA RUBBER TREE, the name generally given to the *Hevea Brasiliensis,* the rubber tree par excellence. It is indigenous to the region of the River Amazon and in the tributary areas of Peru, Bolivia, Ecuador, Colombia and Venezuela. The tree has been recently planted with great success, especially in Ceylon and Malaya. It is a large tree, of slow growth and long life. It has been found 12 feet in circumference. It requires low-lying, rich, deep soil and abundant moisture. It grows wild in Brazil over an area estimated at 1,000,000 square miles; there, however, it does not grow in clumps, being found rather scattered through the tropical forest, but it is well adapted to cultivation as has been demonstrated within recent years in the East Indian Islands. There are several other trees which produce rubber, including the Manihot, which produces the Ceará rubber of commerce, but its habitat is a high, stony and arid country. This is also a native of Brazil, but of the region south of the Amazon. Castilloa, next to Hevea, the best known rubber producer, has its principal range in Central America and southern Mexico. Other trees which furnish rubber are the Hancornia speciosa, which produces the Mangabeira rubber of Brazil and species of Sapium, also the *Ficus elastica* of Assam, the *Funtumia elastica* of Africa and vines of the genera *Landolphia, Clitandra, Carpodinus* and the guayule plant (*Parthenum argentatum*).

INDIAN. See INDIANS, AMERICAN.

INDIAN AFFAIRS. In former years an idea was prevalent that the national government had always striven to dispossess the Indians from the lands they occupied, or had sympathized with such efforts. This was the exact reverse of the truth. From its foundation until now history presents an unbroken record of quarrels between Indians and bordering or interdwelling white settlers, in which the government has been slowly and reluctantly pushed on to interfere; sympathizing with and justifying the Indians against its own citizens, its commissioners usually reporting in their favor and even its generals in later days blaming the whites for the troubles; its courts deciding in their favor; attempting pacification amid local outcries against them, rebuffing appeals for aid and only using its armies to reduce the Indians and its administrative power to remove them when it was no longer politically possible to leave them in possession. Even then, it has meant to deal righteously by them; but the complexity of the problem — one may say its insolubility till the country was very strong and the Indians very weak — along with the universal curse of "spoils" in the administration — hindered success. Until 1887, there was no consistently formulated plan, but there has followed a sequence of government panaceas in a steadily descending line. First, there was to be one vast Indian reservation, large enough to give them all the hunting-room they needed and so far from the United States that our growth would never reach to them and create more troubles; then three great reservations, to prevent so formidable an Indian district and internecine Indian wars; then a number of small ones, to segregate hopelessly hostile tribes, enable better training for civilized existence, and protect them from depredations; lastly, no reservations, but severalty ownership and individual citizenship. These changes of policy have been due not to fickleness or visionary causes, but to broadening experience and varying conditions.

The policy of removing the Indians west of the Mississippi was first formulated by Jefferson, who in a proposed constitutional amendment (1803) set off the Louisiana Purchase north of the Arkansas as a pure Indian country, in which no land was to be sold to whites. This was carried out, on a much reduced scale, in the formation of Indian Territory (q.v.) by act of 30 June 1834; by another act of same date a superintendent of Indian affairs was appointed; no one to trade or settle in the Indian country without permission from him or his agents. Previous to this the Indian matters had been under the War Department; in 1849 they were transferred to the new Department of the Interior, of which they still form a bureau. Under the Commissioner of Indian Affairs are eight inspectors and a large variety of subordinate officials and employees. The Indian agents, though under his control, are appointed by the President for four years, with bonds; on their action depends often peace or war to great white populations, but in too many cases formerly they were the football of politics and sometimes scandalously unfit for their places.

The legal theory, for some time, was that each tribe was a nation, but not a foreign nor independent one; a "domestic dependent nation," but with which, nevertheless, all intercourse was to be conducted through special commissioners appointed by the President. In 1871 Congress abolished this method of procedure, and substituted immediate Congressional control, but the fiction of Indian nations remained; nor, indeed, could any other system well be applied so long as the Indians were recognized as national wards, and could not be made a part of the regular republican system or thrown into the current of unrestricted competition. It was the general plan to let the larger and better advanced ones, the Cherokee, Chickasaw, Choctaw, Creeks and Seminoles (qq.v.), the five "nations" of the Indian Territory, govern themselves and thus develop political life, including a full judiciary system. But the smaller ones could not be thus left, even in leading-strings; and in all, the government has recognized its duty to watch over their ignorance, improvidence and savage instability of will and emotion from either violence or cunning on the part of the whites. Traders with them must have certificates of good character and be licensed by the Indian commissioner, and the goods they sell are subject to regulation; no one can hunt, cut timber or pasture cattle on Indian lands without the agent's permission; intoxicating liquors may not be sold to them. Still more important and beneficial is the educational work, which has not only been carried on by churches, missionary societies and private individuals from early times, but has been actively forwarded by the government. The five civilized nations of Indian Territory had their own school system, of considerable extent; but for others, and even for those where needed, the President was empowered in 1865 to appoint instructors of Indian children in reading, writing, arithmetic and agriculture, and in 1882 to appoint an inspector of Indian schools. See INDIAN, EDUCATION OF THE.

From 1877, when a $20,000 appropriation was made for Indian schooling, to 1900, when over $3,000,000 was appropriated, over $35,000,000 had been thus expended by the government. It had spent since its foundation nearly $400,000,000 on the Indians, outside of the cost of wars against them; and the present expenditure is about $10,000,000 a year.

On 8 Feb. 1887 an act was passed, amended in 1890, to sweep away as soon as feasible, the system of tutelage and pauperization, in the belief that abolition was best for Indians and whites alike. All reservations were to be surveyed; all Indians who wished to take up lands in severalty to a certain amount might do so — and by the act become citizens, as well as all who had previously done so under treaties and Congressional enactments, over 10,000 in number. About 2,000 a year comply with the permission and many of these new citizens are made voters by their States. The Indian population of the United States, exclusive of Alaska, at the close of June 1922, was 340,917, an increase for the last decade, according to the Bureau of Indian Affairs, of 13,500 and the largest number recorded under the more accurate counts of recent years. The population by States was as follows:

State	Population	State	Population
Alabama	405	Nebraska	2,526
Arizona	43,327	Nevada	10,952
Arkansas	106	New Hampshire	44
California	11,091	New Jersey	99
Colorado	779	New Mexico	21,569
Connecticut	159	New York	6,078
Delaware	2	North Carolina	11,853
Dist. of Columbia	37	North Dakota	9,466
Florida	462	Ohio	152
Georgia	125	Oklahoma	*119,158
Idaho	4,053	Oregon	6,677
Illinois	194	Pennsylvania	358
Indiana	125	Rhode Island	106
Iowa	352	South Carolina	304
Kansas	1,496	South Dakota	23,448
Kentucky	57	Tennessee	56
Louisiana	1,066	Texas	2,110
Maine	839	Utah	1,580
Maryland	32	Vermont	24
Massachusetts	550	Virginia	822
Michigan	7,628	Washington	10,920
Minnesota	13,326	West Virginia	7
Mississippi	1,297	Wisconsin	10,498
Missouri	171	Wyoming	1,783
Montana	12,648		
		Total	340,917

*Exclusive of Five Civilized Tribes in Oklahoma (numbering, on 30 June 1922, 101,506) and scattered Indians under Government jurisdiction, except where indicated.

The total value of individual Indian and tribal property, on 30 June 1922, was $727,746,397 as compared with $648,689,092 on the same date in 1912. The property of individual Indians in 1922 had a total value of $529,681,226 made up as follows: Lands, exclusive of timber, $411,070,685; timber, $11,615,800; funds in banks and in hands of superintendents, $34,760,344; homes, furniture, barns, etc., $24,713,360; wagons, implements, etc., $8,857,188; stock, poultry and other property, $38,663,856. The tribal property of the Indians, on 30 June 1922, had a total value of $198,065,171 made up as follows: Lands, exclusive of timber, $89,212,006; timber and stock, $83,916,019; balance of funds in Treasury, $24,937,146.

The progressive tendency of the present day has been reflected in the vigorous activity of the Indian Service branch of the Department of the Interior dealing, as it does, with the intricate complexities involved in the lives of over 333,000 members of the race, both as to the individual and to every phase of their social and industrial functions. Thoroughly convinced that their material and industrial prosperity is more closely attached to their landed interests, the development of agriculture and stock raising has been given an impetus never before undertaken. Not only their own moneys but reimbursable funds made available from appropriations by Congress have been invested in thousands of cattle and other live stock. The Indians are being taught how to make the best use of this wonderful asset and rapidly are realizing that from the farm and the range their material salvation must be obtained. A happy correlation of the instruction given in the schools is being made with the future environment of the boy and girl. The mere acquisition of knowledge is subordinated to the practical teaching of facts and laws which bear directly on everyday life on the farm and in the home. Poverty or dependence on others saps the energies of any individual. The Indian is no exception and the greatest work of the Indian Service is placed on his material advancement. As his herds increase and his lands produce, the

Indian becomes better prepared to assimilate the knowledge which comes from the study of books Love of home and domestic happiness follow as a natural consequence. In 1916, according to the report of the Commissioner of Indian Affairs, the birth rate among the Indians exceeded the death rate for the first time in half a century. The prime factors in bringing about this result are up-to-date hygiene and sanitation, modern methods of combating preventable diseases and the disappearance of the "medicine man." Better habitations are now provided and the infants of the race are safeguarded from birth according to the principles of modern science; hospitals of modern type are provided, displacing the medicine man and his incantations. In consequence of what is being done in educating the Indian to the importance of modern sanitation, tuberculosis, trachoma and other preventable diseases that formerly ravaged the tribes, are fast disappearing. In academic and vocational schools, equal to those of the most progressive white communities, the Indians are being taught the usual school subjects, the common trades, the principles of the government under which they live, good manners, proper living and the niceties of refined society. Consult Sells, C., '84th Annual Report of the Commissioner of Indian Affairs to the Secretary of the Interior' (Washington 1915). INDIAN ASBURY UNIVERSITY. See DE PAUW UNIVERSITY.

INDIAN BEAN, a catalpa (q.v.); specifically the large southern tree (*Catalpa catalpa*), now planted as a shade or ornamental tree all over the country on account of the beauty of its masses of spring flowers and the quaint appearances in autumn of its long, bean-pod-like fruit.

INDIAN BIBLE, the first Indian translation of the Bible in the New England colonies. This translation was made in 1663 by John Eliot, "The Apostle to the North American Indians." It was in the dialect of the Naticks, a Massachusetts tribe of the Algonquins. A second revised and corrected edition was printed in 1685, only 12 copies of which are known to exist. An edition with notes by P. S. Du Ponceau, and an introduction by J. Pickering, was published in Boston in 1822. When the original edition was issued, 20 copies were ordered to be sent to England. A copy of the edition of 1663, with the Epistle Dedicatory, was sold in 1882 for $2,900.

INDIAN BREAD-ROOT, a plant of the genus *Psoralea*; the "large" was *P. esculenta*; the "small" *P. hypogæa.* See BREAD-ROOT.

INDIAN CORN. See CORN, INDIAN.

INDIAN DAY. Indian Day was observed for the first time in the United States in 1916. It is a recognition of the Indian race and intended to be of benefit to them in numerous ways. The census of June 1915, showed that there were 333,010 Indians in the United States. Only seven States have an Indian population of 10,000 or over. They are Arizona, California, Minnesota, Montana, Oklahoma, South Dakota and Washington. Oklahoma leads with 118,358. The expenditures of the United States on account of the Indians in the fiscal year ended 30 June 1915, were $20,592,322.48. The government spent over $4,500,000 alone for the maintenance of Indian schools. Records show that 85 per cent of the total number of gainfully employed Indians are in seven occupation groups. The groups consist of agricultural laborers, farmers, stock raisers, lumbermen, raftsmen, woodchoppers, laborers in manufacturing and transportation, basket makers,

weavers, launderers and laundresses, servants and waiters.

INDIAN FIG. See PRICKLY PEAR.

INDIAN FIRE. See BENGAL LIGHT.

INDIAN FOLK TALES AND MYTHS. See FOLK TALES AND MYTHS OF THE AMERICAN INDIAN.

INDIAN HEAD, Canada, town in Saskatchewan, 40 miles east of Regina, on the Canadian Pacific Railroad. It has extensive grain-growing interests and numbers among its industrial establishments planing mills and lumber yards. The Dominion government maintains here an agricultural experiment station and a forestry school. Pop. 1,285.

INDIAN HEAD, (1) New Jersey, the highest point of the Palisades, 550 feet; so called because it resembles somewhat the head of an Indian. It is in Bergen County, on the Hudson River opposite Hastings, N. Y. (2) The name of a village in Fayette County, Pa. (3) A small town in Maryland, on the Potomac River, below Washington, the seat of a naval station.

INDIAN HEMP. Sometimes called Canada hemp. See APOCYANACEÆ.

INDIAN HIPPO, an American plant. See BOWMAN'S ROOT.

INDIAN HUMPED CATTLE, a species of East Indian oxen (*Bos indicus*), now known only in the domesticated state, distinguished by a high fatty hump on the withers, by the prevalent ashy gray color, large drooping ears, enormous dewlap and several structural peculiarities. They vary in size from those as large as a European ox to the smallness of a half-grown calf. They are the working cattle and draft animals all over India and eastward, more or less locally, to China. They are venerated by the more pious sects of Hindus, especially certain privileged bulls, called Brahma or Brahminy bulls, which wander about the bazaars of cities unharmed and unchecked in their depredations upon market produce.

Humped cattle are known in Madagascar and in Abyssinia, and it has been suggested that the species were originally African. The Abyssinian form is a large animal with huge horns called "galla ox" or sunga. These animals seem to thrive only in hot countries.

INDIAN MADDER. See CHAY-ROOT.

INDIAN MUSIC. Every public ceremony and every important act in an Indian's life was accompanied by song. For each ceremony there existed a special class or type of song and songs for individual celebrations were similarly classified. An Indian can determine at once the class of a strange song by the rhythm of the music. In structure, the Indian song follows the outline of the form which obtains in our own music — a short melodic phrase built on related tones which are denominate chord lines, repeated with more or less variation, grouped into clauses and correlated into periods. The compass of songs varies from one to three octaves. Some songs have no words, vocables being used instead and when once set to a melody they are never changed. Plural singing is generally in unison, on the plains and elsewhere, the women using a high, reedy falsetto tone an octave above the male singers. Men and women having clear resonant voices and good musical intonation compose the choirs which lead the singing in ceremonies. Songs are the property of tribes, societies and individuals. Societies are most careful not to change a word of a song. Indian songs show the development of music, and as such, a study of them is of great historic value. Moreover, they offer to the composer a wealth of melodic and rhythmic movements, and that peculiar inspiration which heretofore has been attained solely from the folk songs of Europe.

Drums vary in size and structure and certain ceremonies in some cases evolved a peculiar type. Whistles of bone, wood or pottery are employed in some ceremonies. Pipes are of recent introduction but are now favorites. The flageolet is widely distributed and is played by young men during courtship, it also accompanies the songs of certain ceremonies. Rattles were universal and of many types. Consult Baker, 'Ueber die Musik des Nordamerikanischen Wilden' (1882); Cringan, 'Iroquois Folk-Songs' (Toronto 1902); Burton, F. R., 'American Primitive Music' (New York 1909); Tiersot, T., 'La musique chez les peuples indigènes de l'Amérique du Nord' (Paris 1910).

INDIAN MUTINY. The British occupation of India had been largely aided by native troops called Sepoys, who were enrolled under British officers in the service of the East India Company. At the close of Lord Dalhousie's sway in 1856, when the whole of India seemed to have been either reduced directly under British rule, or if retaining its native princes to have placed itself under British protection, the Sepoy mutiny, a contingency for which the government ought not to have been altogether unprepared, occurred. Previous symptoms of disaffection had not been wanting. Mutiny had on several occasions broken out in the native army, in a way to indicate how easily, through causes which Europeans, from their defective sympathy with native thought and feeling, could not anticipate these troops might be alienated; but, on the other hand, the general fidelity of the Sepoys merited confidence, and this feeling prevailed over any grounds of suspicion which might have been formed from isolated occurrences. The Sepoys in Bengal were mostly either Mohammedans, or Hindus of the Brahmanical or military castes. The recent annexations had alarmed the native chiefs, while the fanatical Hindus had been deeply offended by reforms, including the successive abolition of various rites of their worship. Two European regiments had been drafted off for the Crimean War, and had not been replaced. Others had been sent to Burma, and in the beginning of 1857 fresh regiments were despatched to Persia, so that only eighteen regiments were left in all Northern India, of which nine were in the Punjab. In Oudh, where, from its recent annexation, disaffection was rife, there was only one British regiment, and Delhi and Allahabad, the two chief arsenals, were guarded by native troops. To add to these favorable circumstances a Hindu devotee had prophesied the termination of British rule at 100 years after the battle of Plassey. A slight incident sufficed

to give point and direction to a spirit of disaffection which so many circumstances tended to favor. At this time the Enfield rifle was introduced into the Bengal army. This rifle was loaded with a greased cartridge, the end of which required to be bitten off at the time of loading. By a natural inadvertence the authorities had neglected to consider how this seemingly trifling requirement might affect the easily excited sensitiveness of the Hindus in regard to caste, and this insignificant circumstance removed the last security, against a united movement of disloyalty among the native troops, by establishing a bond of sympathy between the Mohammedans and Hindus. A report got abroad that the cartridges were to be soaked in cow and pork fat. The prejudices of Hindus and Mohammendans were thus equally involved, and as this rumor rapidly spread, the excited imagination of the Sepoys conceived a conspiracy on the part of the government to convert them forcibly to Christianity, by compelling them to violate the laws of their own religion. When this grievance was explained it was at once removed, the manufacture of greased cartridges at Dumdum was stopped, and the men were instructed to grease them themselves with materials produced at the bazaars. Suspicion once aroused, however, was not to be allayed, and easily found a new object of contention. The paper of the new cartridges was glazed, and it was again alleged that grease was used in its manufacture. The spirit of disaffection became too deep-rooted for any measures of conciliation. Conferences among the disaffected gave rise to ambitious schemes and the original grievances became a pretext in the hands of unscrupulous leaders, whose excesses debarred them even from the plea of patriotism, to extirpate the British power in India. On 26 February the first overt act of mutiny took place at Berhampur, when a regiment refused to receive their cartridges. Another dangerous outbreak took place at Barrackpur on 29 March. The arrival of a British regiment from Burma and the disbandment of the disaffected regiments was thought to have ended the trouble, but it soon became evident that disaffection, which had only wanted an occasion, was spreading rapidly not only among the Sepoys, but among the Hindus generally. Another outbreak took place on 2 May, near Lucknow, when a regiment of cavalry were, by some oversight of the government's instructions, ordered to bite their cartridges. Sir Henry Lawrence succeeded by a show of force in disarming it. A more formidable outbreak occurred about the same time at Meerut, 35 miles northeast of Delhi, when the mutineers, with the assistance of the native inhabitants, indiscriminately massacred the Europeans and escaped to Delhi. The advance-guard of the mutineers reached Delhi on 11 May, and at once entered the city, where they were assisted by the king's servants in massacring the Europeans. The native troops cantoned outside the city in the meantime joined the main body of the mutineers, and assisted in massacring their European officers. About 50 Europeans sought refuge in the palace and placed themselves under the protection of the king, who had placed himself on the throne of the Moguls. These, after some days, were coolly murdered in an open court in presence of a general concourse of spectators, conspicuous among whom was Mirza Mogul, the king's eldest son, who had assumed the title of commander-in-chief. The magazine at Delhi had been blown up by its defenders; but the explosion was only partial, and most of its contents fell into the hands of the mutineers. European troops were now summoned from all quarters. Several regiments were detached from an expedition which was proceeding under Lord Elgin to China, and the Persian War having been concluded, the troops engaged there were immediately recalled. When intelligence of these events reached the Punjab, the mutinous spirit which prevailed among the large body of Hindustani troops there was promptly subdued by disarmament. The Sikhs, though the Punjab had been so recently annexed, continued faithful. But the revolt had spread rapidly elsewhere, and British authority was almost extinct, throughout the Bengal presidency. Everywhere the mutiny was attended with savage excesses — women were outraged, and Europeans, without distinction of age or sex, barbarously murdered. Sir Hugh Wheeler, at Cawnpore, was betrayed by Nana Sahib, maharajah of Bithur, who after offering aid, took the mutineers into his pay, and raising the Mahratta standard, besieged Cawnpore. The siege, or rather bombardment, lasted from 7–24 June, when a capitulation was agreed to, on a sworn promise of Nana Sahib to allow the garrison to retire to Allahabad. But as the embarkation was proceeding the boats were attacked by the Nana's troops and the men indiscriminately massacred. The women and children were for the meantime made prisoners. Sir Henry Lawrence was besieged in Lucknow, where he died on 4 July, from a wound received in a sortie.

Meanwhile mutineers had been converging on Delhi, and British reinforcements were hastening to the besieging camp on the ridge above the city. After protracted operations and repeated reinforcements on both sides, Delhi was taken by assault, 14–20 September. Sir Henry Havelock, who had been engaged in the Persian campaign, had arrived in Calcutta, and immediately set out for Allahabad, to commence operations for the relief of Lucknow and Cawnpore. While his force was victoriously advancing on Cawnpore, Nana Sahib on 15 July barbarously massacred his prisoners, consisting of 210 women and children. Havelock was succeeded in the command, at Lucknow, by Sir James Outram, who held it till relieved by Sir Colin Campbell, on 17 November. At first it was feared that the mutiny might extend to the Bombay and Madras presidencies, and from this cause and the occupation of the troops in Bengal, the mutineers had been left unchecked in Central India. At length columns organized in these presidencies entered Central India, and were united under Sir Hugh Rose. By the operations of these commanders the brave Rani of Jhansi, who died fighting at the head of her troops, was defeated, and Tantia Topi, whose military capacity had prolonged Nana Sahib's resistance, was captured and the mutiny was finally suppressed. The war was substantially closed by June 1858, although the complete pacification of Oudh was not effected till the end of the year. During the mutiny the Sikhs and Gurkhas remained loyal; and the bulk of the population was at least passively so. The suppression of the revolt was followed by a full amnesty to the rank and file who had not borne a hand in the massacre of Europeans, and by the transfer to the British government of the powers possessed by the East India Company. (See INDIA, EAST INDIA COMPANY). Consult the histories of the Mutiny, by Forrest (1904); Holmes, (1898); and Malleson (1878–80).

INDIAN OCEAN, that body of water which has Asia on the north, the East Indian Islands, Nicobar and the Andaman Islands, Australia and Tasmania on the east, Africa on the west, and the Antartic continent on the south. The Cape of Good Hope and the southern extremity of Tasmania may be considered its extreme limits from east to west. Its length from north to south somewhat exceeds 6,500 miles, its breadth varies from 6,000 to 4,000 miles. Its gulfs are the Red Sea, the Gulf of Aden, the Persian Gulf, the Gulf of Oman, the Arabian Sea, the Bay of Bengal and the Great Australian Bight. Its islands are Ceylon, Madagascar, the Laccadives, Maldives, Socotra, Andamans, Nicobar, Mauritius, Bourbon, Kerguelen's Land, etc. The Ganges, Brahmaputra, Irrawaddy, Indus and Euphrates, empty into the Indian Ocean from Asia, and the Zambezi and Limpopo from Africa. The southeast tradewind blows between the 10th and 28th parallels of south latitude from April to October, after which date its limits are contracted; south of these are the northwest winds which prevail almost in the same latitude, in the Atlantic and Pacific. The monsoons are mainly in the north, from the continent of Asia to about latitude 8° S., and from the Mozambique Channel on the west to the western shores of Australia and the Sea of China. They blow for six months, changing about the equinoxes. North of the equator the northeast monsoon prevails from October to April, the southwest from April to October; while south of that the northwest monsoon blows while the northeast is blowing on the north side; and the southeast prevails during the time of the southwest monsoon north of the equator. In the hot season, likewise, when the southeast trade-wind recedes south, the northwest monsoon blows between the equator and the 12th south parallel. The hurricanes of this ocean usually range between lat. 9° and 35° S., extending from Madagascar to the Island of Timor. They usually come from the northeast, and travel southwest and south, returning again east. Their season is from December to April.

According to the most recent soundings the mean depth of the Indian Ocean is 2,300 fathoms, or somewhat greater than that of the Atlantic. The greatest depths are in the eastern part to the south of the equator, where it is estimated that there are fully 50,000 square miles with a depth of over 3,000 fathoms. The deepest sounding has been recorded off the southeast coast of Java, 20,340 feet. Over 13,000,000 square miles lie between the depths of 2,000 and 3,000 fathoms.

The area of land draining into the Indian Ocean is estimated at 6,813,600 square miles, and the rainfall on this land amounts to 4.379 cubic miles of water annually. The rivers flowing from the Asiatic continent are by far the most important, and they carry a vast amount of detritus into the Bay of Bengal and Arabian Sea, these forming immense deposits of blue mud. Along the African coasts, in depths from 100 to 1,000 fathoms, there are glauconitic sands and muds, and on these as well as other coasts, coral muds and sands, and blue and green muds in the shallower depths. In the deeper parts of the ocean, far from land, there are deposits of red clay, radiolarian-ooze, and globigerina-ooze. Toward the Antarctic continent the ocean bed is covered with a diatom-ooze.

The temperature of the surface waters varies much in different parts of the ocean, at different seasons, and under the influence of different winds. In tropical regions the temperature usually varies from 70° to 80° F., and the yearly range is 7° or 8° F. Off the Cape of Good Hope and Cape Guardafui, the annual range may be from 20° to 30° F. Sudden changes of temperature are often noticed off Cape Guardafui when the wind blows off shore.

The cold and deep water is thus drawn up along the coast to take the place of the warm surface water which is driven east by the wind.

The temperature of the water at the bottom is very uniform and subject to little, if any, annual variation. In the Bay of Bengal and Arabian Sea temperatures of 33.7° F. and 34.2° F. have been recorded; these are only very slightly higher than those recorded by the Challenger in lat. 50° S. It is certain, therefore, that this deep cold water is slowly drawn into the Indian Ocean from the Antartic to supply the place of the warm surface currents that are driven south by the winds.

The currents of the Indian Ocean are less constant than in the other oceans, being largely controlled by the monsoons. Some characteristic coral atolls and islands are found toward the central part, such as the great Maldive group, the Chagos, Diego Carcia, and the Cocos Islands. The tropical shores are generally skirted by fringing and barrier reefs which render navigation dangerous. Christmas Island is coral formation, while Saint Paul's, Manuritius, Rodriguez and others are of volcanic origin, and Madagascar, Ceylon, and Socotra, continental islands.

The Indian Ocean was little known to the ancients. The first Europeans who explored it seem to have been the Phœnicians, who in the 7th century B.C., held the thalassocracy, or marine domination, of the Mediterranean. Necho, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phœnicians, into the Indian Ocean, then known as the Erythræan Sea, to circumnavigate Africa. This they did, starting from the Arabian Gulf and regaining Europe by the Columns of Hercules. In the 6th century B.C. this sea was traversed by Hanno, a Phœnician admiral of Carthage. There is still extant his account of the voyage which is translated into Greek under the title 'Hanno's Voyage of Circumnavigation.' The Greek historian Arrian has given us an account of the coasting voyage of Nearchus, one of Alexander's generals, from the Indus to the mouth of the Tigris and Euphrates.

Hippalus, an Egyptian navigator who flourished about the beginning of the Christian era, was the first to observe the regular monsoons of the Indian Ocean, and to profit by them. In the 9th century the Arabs made frequent

voyages across the Indian Ocean. In 1486 the Portuguese rounded the Cape of Good Hope, and in 1498 Vasco da Gama reached the coasts of India by the same route. In 1521 a ship of Magellan's squadron crossed the Indian Ocean in completing the first circumnavigation of the world, and has since been habitually traversed in a direct line between Arabia and Hindustan.

INDIAN OIL TREE. See BUTTER TREE.

INDIAN PAINT, the name of two American plants: (1) the golden seal (q.v.) or orangeroot, which furnishes a yellow color; and (2) the bloodroot. See SANGUINARIA.

INDIAN AND PERSIAN LACQUERWORK. See LACQUERS AND LACQUERWORK.

INDIAN PHYSIC, an American plant. See BOWMAN'S ROOT.

INDIAN PIPE, or **CORPSE-PLANT,** a smooth, waxy-looking, fleshy herb (*Monotropa uniflora*), of the family *Monotropaceæ*, widely distributed in dark, rich woods almost throughout North America and in eastern Asia. It is said to derive some of its food from the roots of other plants, but much is obtained from decaying vegetable matter. From a matted mass of fibrous rootlets the white scaly stems rise to a height of perhaps eight inches, and bear solitary, nodding, white, inodorous flowers during the summer, followed by erect many-seeded fruits.

INDIAN RED, an impure oxid of iron, used as a pigment by painters. It was originally imported from India, but is now chiefly prepared by roasting ferrous sulphate. The sulphuric acid is expelled by the heat, and the red oxid of iron remains behind. It is very permanent, and the color varies from purplish to a yellowish red.

INDIAN RESERVATIONS. When the settlers from Europe came to realize that the Indians had human rights, and ought not to be enslaved or exterminated, the rule was generally adopted of confining the tribes to reservations, both for their own protection from unprincipled whites, and for the security of the white population. New York, Massachusetts, Connecticut, Rhode Island and other States enforced this policy in the colonial period and after independence, and the United States government has carried it out from an early date. Southern tribes east of the Mississippi were removed to the Indian Territory, which since 16 Nov. 1907 has become a part of the State of Oklahoma. Designated by solemn pledge of the National government as a permanent home for their race, there some of the tribes achieved a high degree of civilization, gained considerable wealth and merged into American citizenship. They are largely intermarried with whites, and to some extent with negroes, whom they formerly held as slaves. Other tribes, chiefly from the southwest, were gathered into the Indian Territory, but large Indian reservations, mainly of Sioux, are still maintained in the northwest, and altogether the various tribal reservations in the different States and Territories number 115. The reservations are carefully guarded against intrusion by unscrupulous whites, and provision is made for the intellectual and physical welfare of the Indians, and for leading them to adopt civilized methods of self-support, instead of depending on the chase, which now offers only the most precarious returns, or on government aid, which, however, is not withdrawn under any circumstances while an Indian is in need of it. The sale of intoxicating liquor to Indians is severely punished when detected, but the law is frequently evaded. See CHEROKEE; CHICKASAW; CHOCTAW; CREEKS; INDIAN AFFAIRS; INDIANS, AMERICAN; SEMINOLE INDIANS.

INDIAN RIVER, a long lagoon in the eastern part of Florida, in Brevard and Volusia counties. It connects with the Halifax River at Titusville and extends 100 miles southeast to the ocean at Indian Inlet. Its width varies from 300 feet to 3 miles and it is navigable for vessels drawing five feet. The Indian River is famous for the excellent oranges grown along its banks.

INDIAN SCHOOLS, in the United States, are schools especially established either by private or denominational means or by the national government, for the education of children and youth of the Indian population of this country. For particulars concerning these schools see INDIAN AFFAIRS; INDIANS, EDUCATION OF THE.

INDIAN SHOT. See CANNA.

INDIAN SUMMER, the name given to a period of mild and pleasant weather which generally occurs toward the end of autumn. The term first made its appearance in the last decade of the 18th century. During the next decade the phrase was "second summer." This indicates that the spell of weather known by this name was not generally noticed much before 1800. The term Indian summer became established about 20 years after its first appearance, which was in western Pennsylvania, and spread to New England by 1798, to New York by 1799, to Canada by 1821, and to England by 1830. The term, is, then, not an Americanism; to write in praise of Indian summer is now a literary convention of three continents.

It is by no means easy to account for the origin of the term. The principal characteristics of the season which it describes are haziness, smokiness, and high temperature. Some explanations of the origin of the term are (1) that the Indians predicted such spells of weather; (2) that the smokiness was produced by Indian fires; (3) that this was the last season of Indian attacks on the settlements of the whites; (4) that the season partook of the Indian character of deceptiveness; (5) that the name was given because one of the seasons of East India was similar in character. Horace Walpole used the term in 1778, not in reference to America, but in relation to weather in the tropics. "Squaw winter" was a name for the spell of cold weather preceding the Indian summer, and perhaps the key to the nomenclature is to be sought in this latter term. Analogous terms in use in England and Germany are: "Saint Martin's Summer," "All Hallow Summer," "Saint Luke's Summer," "Old Woman's Summer." Consult *Monthly Weather Review* (Vol. XXX, pp. 19–29; 69–79, Washington 1902).

INDIAN TERRITORY. See OKLAHOMA.

INDIAN TURNIP, a plant, *Arisæma triphyllum*, of the Arum family, known also as Jack-in-the-pulpit. It is one of the best known spring flowers of eastern North America, blossoming in April or May. The leaves are compound, each composed of three large entire leaflets; the "flower" really consists of a club-shaped spike of small greenish flowers surrounded by a large, hooded, corolla-like spathe, usually green striped with purple. In summer a spike of bright red berries is produced. The root is bulblike and contains a very acrid juice.

INDIAN or **WILD TOBACCO,** one of the North American lobelias (*Lobelia inflata*), also called asthma-weed and gag-plant; compare KINNIKINICK.

INDIAN YELLOW, known in commerce as PUREE, a pigment of unknown origin which is exported from India, China and probably Arabia.

INDIANA ("The Hoosier State"), a north-central State of the United States (No. 19 in order of admission) bounded north by Michigan, south by Kentucky, east by Ohio, west by Illinois; extreme length 276 miles, extreme breadth 177 miles; area (No. 34 in United States) 36,350 square miles, 440 water; pop. 1920, according to the official returns of the United States Census Bureau, was 2,930,390. The State boundary in Lake Michigan is an east and west line 10 miles north of the extreme southern point of the lake. The Ohio River runs along the southern boundary, but, by a provision of the Virginia cession of Northwest Territory, Indiana extends only to low-water mark on the north bank of the Ohio. In consequence all islands in the Ohio belong to Kentucky, the Supreme Court having recently held this as Green River Island (Indiana *v.* Kentucky, 136 U. S.) which, although an island at the time of the cession, became connected with Indiana shore by alluvial deposits, and had been governed and taxed as part of Indiana for many years.

Topography.— The surface of the State is comparatively level, the highest point, in Randolph County, in the centre of the eastern tier of counties, being estimated at 1,285 feet above sea-level, and the lowest, at the southwest corner of the State, being 313 feet above sea-level. The Ohio at the southeast corner of the State is 436 feet above sea-level, and Lake Michigan at the northwest corner is 585 feet above sea-level. From the table-land of the east central part of the State, and western Ohio, radiate low water-sheds separating the drainage basins of Indiana. The northern part of the State is quite flat, the central part slightly rolling, and the southern part rather hilly on account of the valleys cut out by water. There are no mountains, and no large lakes, but there are hundreds of small lakes, chiefly in the northern part of the State.

River Systems.— The southern parts of the State are drained to the Ohio River by the Whitewater and smaller tributaries. The central part of the State — about four-fifths of its area — is drained by the Wabash and its tributaries, the most important of which are the White, Tippecanoe, Eel, Salamonie and Mississinewa Rivers, and Wild Cat Creek. The northeastern corner of the State is drained by the Saint Joseph's and Saint Mary's Rivers; these unite at Ft. Wayne to form the Maumee, which flows into Lake Erie. The extreme northern part of the State is drained by another Saint Joseph's, the Calumet and smaller streams, into Lake Michigan. A part of the northwestern section is drained by the Kankakee and its tributaries to the Illinois River. The Wabash is navigated to a limited extent, by small boats, as high as Terre Haute, and also the lower part of White River. The remaining streams are not navigated.

Climate.— The climate of Indiana is mild, ranging from an average of 31° F. in the winter months to an average of 76° in summer. The mean temperature is 53°. The average annual rainfall is 43 inches, that in the southern part of the State being slightly in excess of that in the northern part. Serious droughts and destructive storms are rare. In earlier years parts of the State were malarial, but with the clearing of the forests and the drainage of lands this condition has almost wholly disappeared.

Geology.— The earliest geological formation that outcrops in Indiana is the Hudson and Trenton limestone, of the Silurian Age, which appears in the southeastern corner of the State, throughout the Whitewater Valley and the adjacent region. West of this is a belt of Niagara limestone, which broadens at the north and extends entirely across the State, covering all of a dozen counties and large parts of as many more. On the west of this, and also extending to the State line on the north, are belts of Hamilton limestone and sandstone of the Devonian Age. The remainder of the State — the southwestern corner and a broad belt to the north reaching beyond the Wabash — is of the subcarboniferous and carboniferous formations. The northern and central parts of the State are covered by glacial drift, which in some regions is of a depth of 400 feet.

Soils, Agriculture and Forests.— The soil of the State varies in character, but for the most part is fertile. Originally the southern part of the State, and as far north as the Wabash, was covered with a very heavy growth of forest, mostly of hardwood trees. North of this were low prairies interspersed with sand ridges and dotted with hundreds of small lakes. This region is now found very productive of cucumbers, melons and small fruits in the sandy parts. The richest lands are the alluvial valleys of the streams and the drained prairies. The forests have so far disappeared that the State is now encouraging tree planting. Agriculture is the chief industry of the State, although statistical returns show the products of manufactures greater than those of agriculture. This is partly due to the fact that the profits of manufactures are greater, partly to the fact that new material which is largely agricultural product enters into the value of manufactured products, and partly to the fact that statistics of agricultural products do not include the large amount that goes into the "living" of agricultural labor. According to the last Federal Census, the number of farms in the State on 1 Jan. 1920 was 205,126 as compared with 215,485 in 1910. In 1920 all farm property was valued at $3,042,311,247 against $1,809,135,238 in 1910. Land and buildings were valued at $2,653,643,973 in 1920 as against $1,594,275,596 in 1910. Farm products in 1919 were valued at $497,229,719 as compared with $196,869,691 in 1909. The chief agricultural products in 1919 were: Corn, 262,354,380 bushels; oats, 158,603,938 bushels; wheat, 52,529,723 bushels; potatoes, 2,477,034 bushels; hay, and forage, 5,133,742 tons.

Minerals and Mining.—According to the Federal Census of 1920, Indiana ranked 14th among the States of the Union in 1919 in the value of mineral products. The State ranked ninth in the total number of persons engaged in the mining industries and in the average number of wage-earners employed. The gross value of the products of all mines, quarries and wells in 1919 was $52,840,252. Deducting from this amount a duplication of $50,546 in the value of natural gas which was sold by some producers and resold by others, leaves $52,789,706 as the net value of products. This was an increase of 150.9 per cent over the corresponding figures for 1909. The mining and quarrying industries reported for 1919, ranked according to value of products, were bituminous coal, limestone, petroleum and natural gas, clay and sandstone. The principal mineral industries—bituminous coal, limestone and petroleum and natural gas, accounted for 99.8 per cent of the total value of the mineral products in 1919. Coal mining was the leading industry, reporting products valued at $45,492,726, which was 86.1 per cent of the gross value of all mineral products. Indiana ranked sixth among the States in the value of products of coal mines in the year referred to. The coal-producing area of the State is part of the Eastern Interior Coal Field, which extends into Illinois and Kentucky and covers approximately 7,500 square miles in 22 counties in the southwestern part of Indiana, 18 of which reported production in 1919. The limestone industry was second in importance in value of products in Indiana, and the State, with an output valued at $4,619,801, ranked third in the United States in 1919 as a producer of limestone. The State owes its rank in this industry to the importance of the limestone enterprises in the Bedford-Bloomington district in Lawrence and Monroe counties. The petroleum and natural gas industry was third in importance with an output valued at $2,604,395. The industry is located in two fields—the Lima-Indiana field in east central Indiana, which extends into Ohio; and the southwestern Indiana field, which is continuous with the Illinois field. In the former field 22 counties in Indiana reported production in 1919; in the latter field, 7 counties. The number of petroleum and natural gas wells in the State in 1919 was 2,456 as compared with 10,373 in 1909. Capital invested in the mining industry in 1919 amounted to $63,198,281 as compared with $59.764,947 in 1909. Persons engaged in the industry numbered 28,738 in 1919 compared with 27,669 in 1909.

Manufactories.—The manufactures of Indiana are chiefly a development of the past 50 years. In the earlier period manufacturing was confined almost wholly to supplies for domestic consumption, and was chiefly conducted at the homes of the people. In 1919 there were reported 7,916 manufacturing establishments in the State, employing 277,580 wage-earners, and producing goods of the value of $1,898,753,387. The nine leading industries, ranked according to value of products in 1919, were: (1) iron and steel works, product $199,274,000; (2) slaughtering and meat packing, product $134,029,000; (3) automobiles, product $107,348,000; (4) steam railroad cars, product $86,021,000; (5) foundry and machine shops, product $85,360,000; (6) flour and grist mills, product $75,111,000; (7) automobile bodies and parts, product $71,717,000; (8) cars and general shop construction and repairs by steam railroad companies, product $61,232,000; (9) furniture, product $52,350,000.

The value of flour and grist mill products almost doubled between 1914 and 1919 while the value of slaughtering and packing more than doubled in the five-year period. Notable increases, also, have been shown in iron and steel work, machinery, and automobiles. The central position of Indiana gives facilities for distribution which will presumably cause a continued advance in manufacturing industries.

Commerce and Navigation.—About one-tenth of the people of Indiana (in occupations) are engaged in commerce and transportation. The navigation of the State is limited, being confined to the Ohio River on the south, with the lower Wabash and a small part of the White River, and Lake Michigan on the northwest. The canals of the State are practically abandoned except for water-power. The railroads furnish the chief means of transportation. Commerce is chiefly domestic, but both exportation and importation are steadily increasing.

Fisheries.—Indiana has no fisheries of commercial importance, though it has waters that might be made valuable. Recently laws have been passed for the protection of fish, and some interest is being shown in their propagation.

Railroads and Street Railways.—The railroad mileage of Indiana, in 1919, was 7,337.56 miles, exclusive of second main and side tracks. In 1850 it was 228 miles; in 1880, 4,373. Railroad lines extend through all but three counties in the State. The chief railroad centre is Indianapolis, from which 14 lines radiate. These are connected outside of the city by a belt railway. Taxes and assessments on railroads in 1919 totaled $7,642,958, or $1,079 per mile. There are street railways in all of the cities and larger towns, the total aggregating 195 miles. In 1899 there began an extraordinary development of electric interurban lines. By the close of 1902 about 400 miles of these were in operation, and 500 miles were under construction, while new lines aggregating over 1,000 miles were projected. The total mileage in 1921 was 2,452.71 miles, operated by 28 companies. These lines have made a material change in the transportation of both passengers and freight, and will apparently furnish large competition with the steam railroads. One of these lines operating between Indianapolis and Columbus, Ohio, has added sleeping-cars to its equipment.

State Finances.—On 1 Oct. 1921 the balance in the State treasury of Indiana amounted to $3,075,653.38. The gross receipts during the fiscal year 1921–22 aggregated $33,161,748.98. Advance payments, refunds and transfers, totaling $8,048,727.31 reduced this sum to net receipts amounting to $25,113,021.67. Disbursements during the same fiscal year amounted to $32,060,462.83. Advance payments, refunds and transfers, amounting to $8,048,727.31, made the net disbursements for the fiscal year $24,011,735.52, leaving on hand on 1 Oct. 1922 a balance of $4,439,998.31. The estimated receipts for the fiscal year 1922–23 were $25,968,021.67, while the authorized expenditures for the same period were placed at $24,866,735.52. The assessed value of the real property in the State in 1922 was $3,600,145,119; of personal property, $1,381,051,076. On 30 June 1922 there were reported in Indiana 1,094 national, State (com-

mercial), savings and private banks and trust and loan companies with resources aggregating $922,486,000. The paid-in capital of these banks totaled $75,362,000; their surplus amounted to $34,468,000; their undivided profits to $16,892,000; and their individual deposits to $653,000,000. National banks numbered 251 with assets totaling $384,596,000; State banks numbered 508 and their resources aggregated $228,878,000; loan and trust companies numbered 173 and these had resources aggregating $264,888,000; mutual savings banks numbered five with resources totaling $18,640,000; private banks numbered 157 with resources aggregating $30,829,000.

Education.— Indiana has always given much attention to education and especially since the adoption of the present school law in 1852. At that time there was created a public school fund, the interest on which was to be distributed to the various school districts. The principal factor in this was the profits which the State had derived from the State Bank of Indiana, amounting to about $3,500,000, to which was added $573,000 of the surplus revenue distributed by Congress in 1836, and several smaller funds. To this additions have been made by fines and other public receipts, until in 1914 the common school fund amounted to $11,677,456.65, in which was included the Congressional township fund, derived from the sale of school lands donated by the national government, amounting to $2,479,467.72. This total fund of $11,677,456.65 is held by the several counties, and the interest on it is applied to the support of the public schools.

Under the existing law school attendance during the full term is compulsory for all children between the ages of 7 and 14 years and also for children between 14 and 16 unless they are employed. In 1922 there were 5,636 public elementary schools in the State with 15,456 teachers and 494,760 pupils enrolled. The public high schools numbered 795. These had 5,738 teachers and 96,930 pupils. The total number of children of school age (5 to 20 years) in the State in the census year of 1920 was 861,375. The number reported as attending school that year was 563,523 or 65.4 per cent. The daily average attendance was 457,113 and the average duration of schools was 156 days. Salaries paid teachers in 1920 totaled $19,330,624 and the total expenditure for school purposes in that year was $42,764,748. School expenditures in 1922 were reported as totaling $61,072,874. For the training of teachers there were in the State in 1920 five teachers' colleges (three of them private institutions) with 163 teachers and 5,686 students. There were also two city normal schools in Indiana with 43 teachers and 126 students in 1920.

In 1921 the Indiana Legislature passed a law which provides for a State school levy of seven cents on $100 of taxable property, of which 30 per cent is used to extend to eight months the school term of school corporations unable without aid to provide more than three or four months of school per year. This money may be used also for school supplies, transfers and transportation. There are also a large number of private schools, notably those maintained by the Roman Catholics and Lutherans for children of all ages, and a number of academies, seminaries, institutes, boarding-schools, military institutions, colleges, normal schools, etc., for intermediate education.

In addition both Indiana University at Bloomington and Purdue University at Lafayette receive aid from the State. Indiana University has an income derived from a State tax levy and the interest on an endowment fund raised by State taxation. Purdue also has an income derived from State tax levy and interest on endowments, as well as payments made to it annually by the United States government as an agricultural school.

Among the private institutions for higher education the more important are Wabash College (Presbyterian), University of Notre Dame and Saint Meinrad's College (Roman Catholic), DePauw University (Methodist), Earlham College (Society of Friends), Franklin College (Baptist), Hanover College (Presbyterian), Northern Indiana Normal (non-sectarian), and the University of Indianapolis. The last named was formed by the union of Butler College (Christian) with the Medical College of Indiana, the Indiana Dental College, and the Indiana Law School, all of which are located at Indianapolis.

An important branch of educational work in Indiana is the development of libraries. A feature of the school system adopted in 1852 was the establishment of a free public library in each township in the State. The State expended $273,000 for books, and the system was received with great public favor, but no provision was made for maintaining or increasing the libraries, and in the pressure of the war times they were allowed very generally to fall into ruin. To some extent these have been replaced as school adjuncts by the libraries of the Young People's Reading Circle, which are found at many of the schoolhouses of the State. These libraries contain about 500,000 volumes. There has also been a notable development of town and city libraries, 138 towns having accepted donations from Andrew Carnegie, aggregating $2,097,000, agreeing to maintain libraries in the buildings thus provided. There are 33 others that are maintaining libraries in buildings provided by themselves. The general supervision of library work is lodged in the Public Library Commission, which has charge of a system of traveling libraries furnished by the State. It also maintains a school for the training of librarians engaged in the work in Indiana.

Churches.— The principal religious denominations of Indiana in the order of their strength are the Methodists, Roman Catholics, Disciples or Christians, Baptists, Presbyterians, United Brethren and Lutherans.

Charitable and Penal Institutions.— The State maintains 10 charitable and six penal institutions, at an annual cost of over $1,500,000. Of the former five are hospitals for the insane located respectively at Indianapolis, Logansport, Richmond, Evansville and North Madison. These contain in varying numbers about 5,000 inmates. The annual cost of maintenance is about $1,025,000, or $205 per capita. The other charitable institutions are the School for the Blind, Indianapolis, inmates 121, per capita cost $358.96; School for the Deaf, Indianapolis, inmates 298, per capita cost $314; Soldiers' and Sailors' Orphans' Home, Knightstown, inmates 448, per capita cost $251; Soldiers Home, Lafayette, inmates 909, per capita cost $216;

School for Feeble-Minded, Fort Wayne, inmates 1,263, per capita cost $148; Village for Epileptics, New Castle, inmates 218, per capita cost $263.69; Tuberculosis Hospital, Rockville, inmates 119, per capita cost $468. The correctional institutions are the State Prison, Michigan City, inmates 1,158, per capita cost, $152, earnings, $67,438; Indiana Reformatory, Jeffersonville, inmates 1,004, per capita cost $208, earnings $82,568; Women's Prison, inmates 116, per capita cost $257, earnings $4,795; Girls' School, Clermont, inmates 288, per capita cost $278, earnings $119; Boys' School, Plainfield, inmates 552, per capita cost $215, earnings $939.

The legislature of 1913 made provision for a State farm, for male offenders not felons, and a tract of 1,584 acres was purchased near Putnamville, in Putnam County. In September 1915, there were 604 prisoners at the farm and the institution was recognized as on a successful footing. The Robert W. Long Hospital at Indianapolis, established under a bequest to the State by Doctor Long, was opened 15 June 1914. It has a State appropriation of $50,000 a year, in addition to receipts from pay patients. The State has the convict-contract-labor system, but the legislature of 1909 provided for its abolition in 1920. The convict labor is all done within the prisons. The State has the indeterminate sentence system with commutation of time for good behavior. In addition to the State institutions each county maintains a poor asylum. In these, and the Marion County asylum for the incurable insane, there is an annual population of about 3,500 inmates, of whom about two-thirds are men and one-third women. Of these inmates some are classed as insane and others feeble-minded. There are in the State 33 orphans' homes, in which there are annually about 1,800 inmates, of whom 1,300 are boys and 500 girls. At the same time the Board of State Charities reports 2,989 orphan children maintained in private homes, without public expense.

State Government.— The elective State offices are held for periods of two years, with eligibility restricted to four years in any period of six years, except as to the governor, lieutenant-governor and geologist, whose terms are four years. No one is eligible to the office of governor or lieutenant-governor for more than four years in any period of eight years. The governor's salary is $8,000, with an allowance of $1,800 for house rent. The governor's veto power extends to all laws passed by the legislature, but the veto may be overthrown by a majority vote in both houses. The legislature meets once in two years and may be called in special session by the governor; regular sessions are limited to 60 days and special sessions to 40 days. The Senate is composed of 50 members elected for four years each, and the house of 100 members elected for two years each. The members receive $6 a day while in session, and $5 for each 25 miles traveled in reaching the capital and returning home. The State is required to be redistricted for legislative purposes every six years. The present Constitution was adopted in 1851, and is very generally considered unsatisfactory, especially as to legislative representation and the location of the appointing power. It can be amended only by the majority vote of both houses of two consecutive legislatures, followed by a majority vote of the electors of the State.

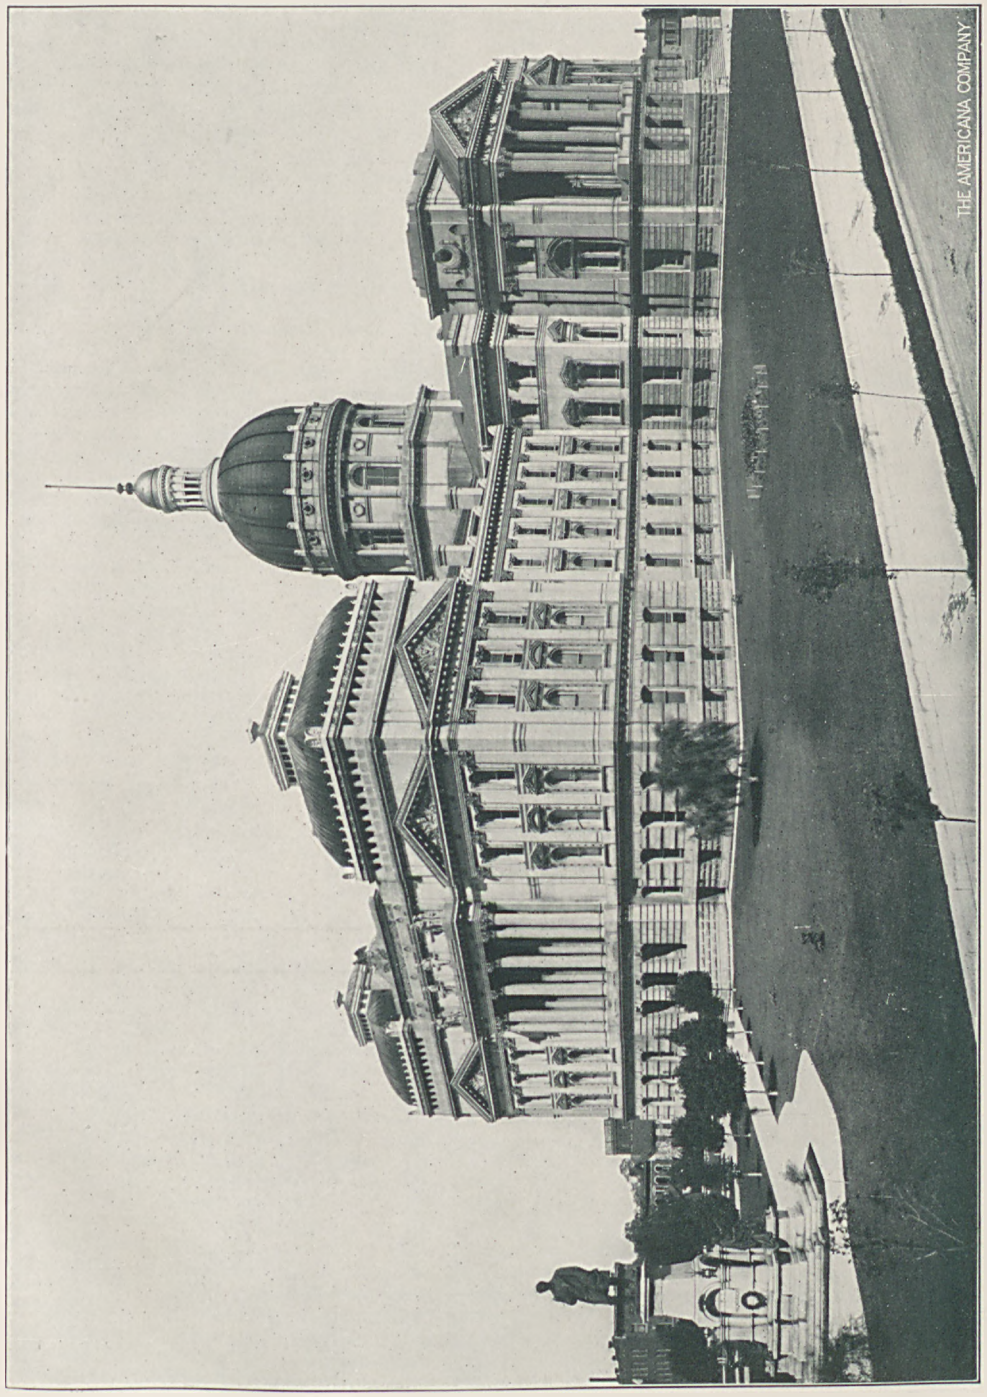
Congressional Representation.— The State has 13 representatives in Congress.

Population and Divisions.— The population of Indiana territory in 1800 was 5,641, but only about 2,500 of this was within the boundaries of the State. In 1810 the population of the territory, with practically the same boundaries as the State, was 24,520. A territorial census taken in 1815 showed 63,897 inhabitants. After the admission of the State the census returns were as follows: 1820, 147,178; 1830, 343,031; 1840, 685,866; 1850, 988,416; 1860, 1,350,428; 1870, 1,680,637; 1880, 1,978,301; 1890, 2,192,404; 1900, 2,516 462; 1910, 2,700,876; 1920, 2,930,390. Of the population in 1920, 150,868 were foreign born and 80,810 were negroes. The tendency of the negroes is to gather in the cities, more than one-fourth of the entire number being found at Indianapolis, and a 14th at Evansville.

The State has 92 counties, whose names and county-seats are as follows:

Adams, Decatur.	Lawrence, Bedford.
Allen, Ft. Wayne.	Madison, Anderson.
Bartholomew, Columbus.	Marion, Indianapolis.
Benton, Fowler.	Marshall, Plymouth.
Blackford, Hartford City.	Martin, Shoals.
Boone, Lebanon.	Miami, Peru.
Brown, Nashville.	Monroe, Bloomington.
Carroll, Delphi.	Montgomery, Crawfordsville.
Cass, Logansport.	Morgan, Martinsville.
Clark, Jeffersonville.	Newton, Kentland.
Clay, Brazil.	Noble, Albion.
Clinton, Frankfort.	Ohio, Rising Sun.
Crawford, English.	Orange, Paoli.
Daviess, Washington.	Owen, Spencer.
Dearborn, Lawrenceburg.	Parke, Rockville.
Decatur, Greensburg.	Perry, Cannelton.
Dekalb, Auburn.	Pike, Petersburg.
Delaware, Muncie.	Porter, Valparaiso.
Dubois, Jasper.	Posey, Mt. Vernon.
Elkhart, Goshen.	Pulaski, Winamac.
Fayette, Connersville.	Putnam, Greencastle.
Floyd, New Albany.	Randolph, Winchester.
Fountain, Covington.	Ripley, Versailles.
Franklin, Brookville.	Rush, Rushville.
Fulton, Rochester.	Scott, Scottsburg.
Gibson, Princeton.	Shelby, Shelbyville.
Grant, Marion.	Spencer, Rockport.
Greene, Bloomfield.	Starke, Knox.
Hamilton, Noblesville.	Steuben, Angola.
Hancock, Greenfield.	St. Joseph, South Bend.
Harrison, Corydon.	Sullivan, Sullivan.
Hendricks, Danville.	Switzerland, Vevay.
Henry, Newcastle.	Tippecanoe, Lafayette.
Howard, Kokomo.	Tipton, Tipton.
Huntington, Huntington.	Union, Liberty.
Jackson, Brownstown.	Vanderburg, Evansville.
Jasper, Rensselaer.	Vermilion, Newport.
Jay, Portland.	Vigo, Terre Haute.
Jefferson, Madison.	Wabash, Wabash.
Jennings, Vernon.	Warren, Williamsport.
Johnson, Franklin.	Warrick, Boonville.
Knox, Vincennes.	Washington, Salem.
Kosciusko, Warsaw.	Wayne, Richmond.
Lagrange, Lagrange.	Wells, Bluffton.
Lake, Crown Point.	White, Monticello.
Laporte, Laporte.	Whitley, Columbia City.

Chief Cities.— The largest city in Indiana is the capital, Indianapolis, with a population (1920) 314,194. Next in size are Evansville (85,264), Fort Wayne (86,594), Terre Haute (66,083), and South Bend (70,983). Each of these cities has a charter specially made for it, though under guise of a general law. These charters are of recent creation — the oldest made in 1891 — and establish advanced forms of city government. Of cities of secondary importance may be named Muncie (36,524), New Albany (22,992), Anderson (29,767), Richmond (26,765), Lafayette (22,486), Marion (23,747), Logansport, (21,626), Elkhart (24,277), Gary (55,378), East Chicago (35,967), Hammond (36,004), and Kokomo (30,067).



State Capitol at Indianapolis

History.— The first-known visits of white men to Indiana were those of Sieur de la Salle, who followed the Ohio River along its southern boundary in 1669–70, and crossed its northwestern corner by way of the Saint Josephs-Kanakakee portage in 1671. There were no Indians living below the Wabash at that time and probably not many in the northern part of the State, but those there were LaSalle induced to join his confederacy against the Iroquois, and they all removed to the Illinois River, leaving Indiana practically uninhabited. After some years they began moving to the East, reaching Detroit by 1712, and shortly afterward located at points along the Maumee and Wabash rivers. The Delawares, who afterward lived in the central part of the State, on White River, came there about 1750. It is probable that the French first placed representatives at the Indian villages near the site of Fort Wayne, and next, about 1720, at Ouiatanon — on the north side of the Wabash just below Lafayette — and that there were stockade forts at these places, but there is nothing to indicate a permanent settlement at either place. The post at Vincennes was established in 1731, largely under the influence of Father De Beaubois, a Jesuit who had been stationed at Kaskaskia. Families located there soon afterward, and it remained a permanent settlement, though there is but one land grant recorded of date prior to 1736. The French posts were small and unimportant, and the history of the region under French and British rule presents no very striking features. In 1778 Vincennes was surrendered to representatives of Gen. George Roger Clark, and the Wabash country was brought under American control. A recapture by the British was followed by a second taking by Clark in 1779. The region was ceded to the United States by the treaty of 1783, and was included in the territory northwest of the Ohio River, by the ordinance of 1787. It was thus governed until 1800, when Indiana Territory was formed, including all of the Northwest Territory except Ohio. From Indiana Territory, Michigan Territory was cut off in 1805, and Illinois Territory in 1809, leaving it with practically the present State boundaries. By act of Congress of 19 April 1816, Indiana was authorized to form a State government, and the State was formally admitted by Act of 11 Dec. 1816. In the meantime a State Constitution had been adopted on 29 June; State officials had been elected, and the State government had been actually inaugurated on 7 November.

There was almost continuous Indian troubles in the Ohio Valley from 1788 to 1795, when, after General Wayne's successful expedition, peace was made at Fort Greenville. After that date the American immigration began and there was no material trouble with Indians until the formation of Tecumseh's confederacy in 1811. The Indians were overwhelmed at the battle of Tippecanoe (q.v.) on 7 November of that year, by the troops under General Harrison, and sued for peace, but when the war with England came on there were Indian hostilities of minor importance continuing until the close of the war in 1815. After that year there was a gradual extinction of Indian titles, the Indians being concentrated in the northern part of the State and finally removed west of the Mississippi. The last removals occurred in 1836 and 1838.

The sobriquet "Hoosier," commonly used to designate the State and its people, was first applied to them about 1830. It was not coined for that purpose, as is commonly supposed, but was a slang word signifying an uncouth rustic, which was in common use in the South at the time, and is still commonly used there in that sense.

The history of the State after its admission was chiefly that of peaceful development — clearing lands, opening roads, building towns and cities and establishing industries. The most notable feature was the disastrous internal improvement enterprise on which the State entered in 1836. It contemplated transportation routes on seven main lines, involving the construction of 1,289 miles of railroads and canals. That the routes were fairly well chosen is shown by the fact that they are now practically all occupied by successful railroad lines. The chief defect was that the improvements were mostly high-line canals, and the breaks in these before completion caused such great damage that the estimated cost was enormously increased. The financial panic of 1837 added to the difficulties, and the effects of this were aggravated by the general entering of the States on such enterprises on borrowed capital. The total debts of the several States swelled from about $13,000,000 in 1830 to $207,894,613 in 1842. In 1839 Indiana was unable to realize on the sales of her bonds, and was forced to default interest on those already issued. The canals and roads being unfinished, did not furnish the revenues anticipated. Compromises were effected by which the work done was turned over to creditors, but the State was left with a debt of about $10,000,000 without any property to represent it. In all, Indiana built 453 miles of canals, at a cost of $7,725,262, all of which are now abandoned so far as transportation is concerned. But under private management, and more favorable conditions, the transportation lines developed rapidly, and in 1849 the one railroad originally contemplated was paying 8½ per cent dividends on its stock. In 1860 there were 2,126 miles of railroads in successful operation in the State.

In the war with Mexico, Indiana furnished troops to the number of 4,470. Of these there were killed and wounded 183, and died of other causes 218. When the Civil War began the State occupied an important position, and its resources were utilized to the uttermost by its war governor, Oliver P. Morton. The State furnished 196,363 men for the war, and 784 paid for exemption, or in other words supplied 74.3 per cent of her total population capable of bearing arms, by the census of 1860. Only one State in the Union surpassed or equaled this record, Delaware being credited with 74.8 per cent of her military population. But of the supply credited to Delaware nearly one-tenth was in money commutation for exemption, and nearly one-tenth of the men in actual service was colored. On the basis of white troops furnished for three years or more of service, Indiana supplied 57 per cent of her military population of 1860, and on this basis was surpassed only by Kansas, which is credited with 59.4 per cent. Of the troops sent by Indiana 7,243 were killed or mortally wounded in battle, and 19,429 died of other causes, making a total death loss of over 13 per cent of all troops furnished. One feature of the war period in Indiana, and some

adjoining States, was the formation of secret treasonable societies known as Knights of the Golden Circle, and later Sons of Liberty. These attracted much attention at the time, and much comment later, but in reality they were neither extensive nor dangerous. They were organized with a system of "circles within circles," with mysterious rites and blood-curdling oaths, but the masses of the members understood that they were merely for mutual protection, and the treasonable designs were affairs of the inner circles. Among their members there were a number of government detectives who kept the authorities informed as to every movement, and at the final exposure the chief witness for the government was Felix Stidgers, a detective who had become so prominent in the order that he was made "Grand Secretary for Kentucky," and knew all of the secrets of the order. As is aptly stated by Governor Morton's biographer, "No one can read the history of the secret organizations in Indiana and not feel that, widespread as they were, there was not an instant in which they were not securely within the grasp of the war governor." After the war, Indiana became peculiarly a political battleground. In 1868 the Republicans elected Conrad Baker governor by less than 1,000 plurality, and in 1872 the Democrats elected Thomas A. Hendricks to that office by the narrow plurality of 1,148, although General Grant received the vote of the State for President. After 1872 neither party carried the State at two consecutive Presidential elections until after 1896, and neither carried it by a majority of all the votes cast, or by a plurality of as much as 20,000. One result of this close balance has been an improvement in State legislation, the Democrats leading in the legislature of 1889 which they held although they had lost the State offices and the Presidential vote of the State in the preceding year. Indiana in that year adopted the Australian ballot system, being the second State in the Union to do so, with some improvements that have been extensively copied. Other notable reform laws are a school-book law that has made a large reduction in the cost of books used in the common schools; a Board of State Charities law that has greatly improved the charitable and penal institutions of the State; a fee and salary law putting officials on salaries and requiring the payment of all fees into the public treasuries; a compulsory education law; laws for the encouragement of public libraries; laws for the incorporation of cities which provide the most modern modes of city government; laws for the reform of county and township government providing supervisory boards to which local legislation is entrusted, and a tax law that has been largely effective in equalizing taxation and has been copied elsewhere. Another feature of Indiana's development that has attracted notice in later years is its production of native writers of poetry and fiction. Among the former may be named Joaquin Miller, John Hay, William Vaughan Moody, John James Piatt and James Whitcomb Riley; among the latter Gen. Lew Wallace, Maurice Thompson, Edward Eggleston, Charles Major, Meredith Nicholson, Booth Tarkington, Elizabeth Miller (Hack) and Annie Fellows Johnston. There have also been many native writers in other lines of no mean ability.

The list of governors of Indiana is as follows:

Territorial		
William H. Harrison		1800–11
John Gibson		1811–13
Thomas Posey		1813–16
State		
Jonathan Jennings	Democrat-Republican	1816–22
Ratliffe Boone (acting)	" "	1822
William Hendricks	" "	1822–25
James B. Ray	" "	1825–31
Noah Noble	" "	1831–37
David Wallace	Whig	1837–40
Samuel Bigger	"	1840–43
James Whitcomb	Democrat	1843–48
Paris C. Dunning (acting)	"	1848–49
Joseph A. Wright	"	1449–57
Ashbel P. Willard	"	1857–60
Abram A. Hammond (acting)	"	1860–61
Henry S. Lane	Republican	1861
Oliver P. Morton	"	1861–67
Conrad Baker	"	1867–73
Thomas A. Hendricks	Democrat	1873–77
James D. Williams	"	1877–80
Isaac P. Gray (acting)	"	1880–81
Albert G. Porter	Republican	1881–85
Isaac P. Gray	Democrat	1885–89
Alvin P. Hovey	Republican	1889–91
Ira J. Chase	"	1891–93
Claude Matthews	Democrat	1893–97
James A. Mount	Republican	1897–1901
Winfield T. Durbin	"	1901–05
J. Frank Hanly	"	1905–09
Thomas R. Marshall	Democrat	1909–13
Samuel M. Ralston	"	1913–17
James P. Goodrich	Republican	1917–21
W. T. McCray	"	1921–25

JACOB PIATT DUNN,
Secretary of the Indiana Historical Society.

INDIANA UNIVERSITY, the State university located at Bloomington. In accordance with a provision of the State constitution, the legislature passed an act in 1820 providing for the establishment of a State seminary, which was opened in 1824 under the name of Indiana Seminary; in 1827, it was raised to the dignity of a college, and in 1838 the name was changed to Indiana University. In 1867 the university was opened to women, and has since been coeducational in all its departments. The university is the head of the public school system of Indiana, and no tuition fee is charged; the government is by a board of trustees which reports biennially to the governor. Courses are offered in languages, science and history, graduates receiving the degree of A.B. or B.S. The degrees of Ph.D. and A.M. are given for graduate work; there are also a school of law and a school of medicine connected with the university. There is a biological experiment station on Winona Lake, under university control, and a summer session is maintained. In 1922–23 the university reported: faculty, 240; students, 3,256.

INDIANAPOLIS, Ind. capital of the State, county-seat of Marion County, the largest city in the State and the 21st in the United States; situated on the west fork of White River. It is 60 miles from the centre of population of the United States. It is the centre for 16 radiating railroads, which connect it with Chicago, 184 miles northwest, Cleveland, 283 miles northeast, Saint Louis, 240 miles southwest, Louisville, 110 miles south, Cincinnati, 111 miles southeast, Columbus, 181 miles east, New York, 819 miles east, and other termini in Ohio, Michigan, Illinois and Indiana. Its area is 39.45 square miles.

The site was selected in 1820 as the location of the capital by a legislative commission and

INDIANAPOLIS, IND.

Soldiers' Monument

its name was adopted by the legislature in session at Corydon, 6 Jan. 1821. The first plat included a square mile, which was laid out with broad rectangular streets and avenues radiating from a central circle. The character of the plan was undoubtedly influenced by l'Enfant, the designer of the city of Washington, D. C., for one of the surveyors who made the town plat had aided in the work at the national capital. While the additions to the city have not been developed upon the same broad lines, most of them have been treated liberally and the city is noted for its wide streets, well paved and beautifully shaded. The city is very level, nearly all of its area being 700 to 800 ft. above sea-level. There are 550.6 miles of platted streets, of which 255 miles are paved, 133 miles with asphalt, 80 miles with brick, 23 miles with wooden blocks and 12 miles with macadam. The chief business streets are Washington street, which is a section of the old National road projected and partly completed to run from Baltimore to Saint Louis; Market, Maryland and Georgia streets, all running east and west; Meridian, Pennsylvania, Delaware and Illinois streets, running north and south, and Massachusetts, Indiana, Virginia and Kentucky avenues, which are diagonals, radiating from the circular Monument Place. This central circle contains the State's monument to its soldiers and sailors, perhaps the most successful of the innumerable monuments erected by towns, cities, societies and states in commemoration of the nation's defenders, and generally regarded as one of the greatest in the world from an artistic point of view. The finest residence streets are Delaware, Meridian, Washington Boulevard, Maple Road and Pennsylvania. Several other residence districts are particularly well designed and cared for, such as Woodruff Place—a residence park, with esplanades, fountains, statues, etc.,—which has a town government of its own, though completely surrounded by the city; Morton Place, Meridian Heights and Irvington.

Public Service.—The first water supply and the first sewer system were constructed in 1870 to 1875 and but little else was done in the way of comprehensive public improvements until after the adoption of the present efficient charter in 1891. Prior to that year the city government had been by mayor and council. Public-spirited citizens who recognized the impossibility of securing comprehensive public improvements, through the Commercial Club agitated the adoption of the new charter, which separated the legislative and administrative functions of the city government, making the mayor and his appointees fully responsible for the latter. The first Board of Public Works devised a broad system of improvement, including sewerage, paving and street cleaning, which was supplemented in 1895 by a Park Commission. Under these two boards the progress in the establishment of municipal public works adding to the beauty and convenience of the city has been rapid. As a step preliminary to the era of improvement which began in 1890 a paving exposition was held for the purpose of educating the people of the city regarding paving materials and methods. It was the first ever held in America and attracted attention throughout the country. Official delegations were sent to it from about 500 cities. Prior to 1890 less than two miles of pavements had been laid. The amounts expended after the adoption of the new charter in 1891 to the year 1902, inclusive, were as follows: for pavements of asphalt, $2,726,668.01; brick, $1,011,214.39; wooden block, $969,652.82; macadam, $154,522.91; gravel, $757,112.50; for alley improvements, $46,655.26; for cement walks, $879,610.21; for brick walks, $65,995.41; making a total for paving of $6,611,431.51. The amounts expended up until 1 Jan. 1916, were as follows: for 133.13 miles of asphalt pavements, $5,217,493; for 80 miles of brick pavements, $2,550,409; for 23 miles of wood block pavements, $1,385,409; for 16.76 miles of bituminous concrete pavements, $583,039; for 8.58 miles of macadam pavements, $321,803; for 139 miles of gravel roadway, $1,593,311; for 467 miles of cement sidewalks, $2,267,990, and for 25 miles of brick sidewalks, $65,995, making a total of $13,985,000. The city has 377.78 miles of sewers which were constructed at a cost of $6,003,-446.15. The grand total of expenditures for permanently improved highways, walks and sewers up until 1 Jan. 1916 was in excess of $20,000,000. The waterworks owned by the Indianapolis Water Company have been developed with the city. The system of pumping by direct pressure is used and a system of filter beds to purify the water taken from White River is operated in conjunction with the system of pumping from driven wells. The company maintains four pumping stations with a daily capacity of 110,000,000 gallons. The daily average pumpage for 1916 was 23,000,000 gallons. For fire service the company increases its pressure from 100 to 110 pounds. The company maintains 3,400 fire hydrants for the city at an annual rental of $45 each, or at a total cost of $153,000 a year. Electric lights are in general use, the household rates being 6½ cents per kilowatt hour. Open flame arcs of 500 candle power are used almost exclusively for street lighting, although the city maintains 700 gas lights of the boulevard type at an annual cost of $15 each. The total appropriation for street lighting for 1916 was $160,000 for which the city was rendered lighting service under contract as follows: 2,800 arcs at $41.98 a year each; 2,100 underground-wired pedestal boulevard incandescents at $27.71 a year each; 100 overhead incandescents at $17.83 a year each and 700 gas boulevard lights, maintained by the city, at a cost of $15 a year each. The police department contains 435 men and is maintained at a cost of $511,771.47 a year. The police court, city clerk, detective and police departments are housed in a handsome building and the city and county maintain a workhouse where prisoners are sentenced for short terms. Four police substations are maintained. The fire department contains 360 men and costs for maintenance $478,407.68 a year. Thirty stations are maintained in addition to the new central fire station. The department has 76 pieces of apparatus as follows: 13 horse-drawn steamers; four combination motor pumps; eight motor hose wagons; 23 horse-drawn hose wagons; three horse-drawn chemical wagons; two motor squad wagons; five motor chiefs' cars; one tractor aerial truck; one tractor water tower; four motor service trucks; eight horse-drawn service trucks and two motor telegram repair wagons. The Indianapolis Salvage

Corps, financed by insurance companies, maintains two motor salvage squads that are operated in conjunction with the fire department. There are 75 miles of underground conduits used by the telephone, telegraph and electric light companies and 170 miles of street car lines owned by the Indianapolis Street Railway Company and operated under lease by the Indianapolis Traction and Terminal Company. The city is the most prominent interurban centre in the world. It has six interurban systems, made up of 13 lines, which in 1914 carried 7,912,763 passengers to and from the city, an average of 19,213 a day, 712 passenger cars being handled each day in the largest and most pretentious interurban station in the United States. Freight cars to the number of 23,500 are handled out of this station, owned by the Indianapolis Traction and Terminal Company, each year.

During the two-year period dating from 1914 to 1916 notable public improvements were either completed or under the process of construction. To eliminate such disasters as befell the city during the flood of 1913 a concrete flood prevention levee was constructed for more than a mile along the west bank of White River. The levee is 40 feet high and on the river side is faced with a concrete apron. On its crest is a 60-foot roadway, which makes a valuable addition to the city's boulevard system. This levee, which was financed under a special act of the Indiana General Assembly providing for the issuing of long term bonds, cost $1,350,000, and was completed in 1916. A movement to elevate the railroad tracks throughout the city was started by the Commercial Club Elevated Track Commission in 1894, and after 10 years of contention in courts and legislatures the work was begun. In 1914, at a cost of $1,000,000, the city made an immense sewer out of Pogues Run, a small stream running through the business district, that the tracks might be elevated successfully. Plans have been completed for track elevation and the work which will cost approximately $7,000,000 was well underway in 1916. It is expected that it will be completed in 1920.

Parks and Cemeteries.— The public park system includes 16 parks of 1,735.13 acres in area. Riverside Park, purchased in 1898, contains 934.6 acres and is valued at $1,277,000. Other parks, their area and estimated values follow: Fall Creek Parkway, 207.93 acres, $523,570; Garfield Park, 128.52 acres, $304,723; Brookside Park, 93.05 acres, $180,000; Pleasant Run Parkway, 93.48 acres, $180,000; White River Parkway, 45.55 acres, $82,000; Woollen's Garden, 44 acres, $50,000; Ellenberger Woods, 40.95 acres, $40,000; Brookside Parkway, 34.16 acres, $64,500; Rhodius Park, 33 acres, $47,000; Military Park, 17.3 acres, owned by the State of Indiana; Willard Park, 14.71 acres, $100,000; Burdsal Parkway, 11.49 acres, $43,000; Spades Place, 10.4 acres, $24,000; Greenlawn, eight acres, $60,000; University Square, four acres, owned by the State of Indiana; Highland Square, 3.98 acres, $25,000 and Saint Clair Square, three acres, owned by the State of Indiana. The total value of park land owned by the city is estimated at $2,981,293. The city street railway company owns two parks of unusual beauty a short distance from the city. Since the park commission was established in 1895 the city has expended $4,419,395.31 on park property, the sum of $1,299,435.82 having been expended in park maintenance; $1,586,863.39 for improvements and $1,533,096.10 for the acquisition of additional park property. The first cemetery of the the city, Greenlawn, has not been used as such for many years and is kept in park form by the board of park commissioners. Crown Hill cemetery, one of the notable cemeteries of the country, embraces over 540 acres. There are also Roman Catholic, Lutheran and Jewish cemeteries.

Notable Features of City.— It is in population, transportation facilities and volume of business transacted the largest inland city, not on a navigable body of water, in the United States. It has three direct steam roads to coal fields of Indiana. It has two direct roads to the Bedford or oolitic stone fields of Indiana; in the output of automobiles it is the second city of America and the Indianapolis Motor Speedway, a 2½-mile oval track paved with brick, is the greatest and first speed course of its kind in the world. The city has 200 wholesale and jobbing houses, representing all lines of trade. The Citizens' Gas Company, operating 550 miles of mains, provides the householder with fuel at 55 cents a thousand feet, the scale decreasing to 40 cents for large consumers. It has 25 modern office buildings and 63 hotels. A total of $60,000,000 worth of live stock is handled at the Indianapolis Stock Yards annually. The city is the centre for the manufacture of quartered oak veneer. An automatic telephone system was installed for the entire city in 1916.

Buildings.— The Indiana State House, costing $2,000,000, and built of Indiana oolite stone, is perhaps the most notable building. With its grounds it occupies two large blocks. The county building was completed in 1878 at a cost approximating $1,750,000. The Federal building, containing the post office, custom-house and United States courts cost $2,400,000. Other municipal buildings of note are the city hall, which cost $500,000, and the police building, the public library and some of the new public school buildings. Tomlinson Hall, a bequest by Dr. J. M. Tomlinson, is a public building, its lower story being used as a market. The Indianapolis Art Association owns an art museum and school. Notable among the city's business buildings are the Indiana National Bank, Fletcher Savings and Trust, the Merchants Bank, the Law building, the Lemcke, the Lemcke Annex, the Hume-Mansur, the Newton-Claypool, the Indiana Pythian building, the Odd Fellows building, the Meridian Life building, the State Life building, the Kahn building, the News building, the Occidental building, the Claypool, Severin and Washington Hotels, the Majestic building, the Indianapolis Board of Trade and the Indianapolis Chamber of Commerce buildings, the Murat Temple, containing the Murat Theatre, the Masonic Temple and the buildings occupied by the department stores of the William H. Block Company and L. S. Ayres & Company. During the five or six years prior to 1916, the city enjoyed an unprecedented building growth. Other buildings of large proportions are under process of construction. The Columbia Club building is an important feature of one quadrant of Monument Place, which surrounds the Indiana State Soldiers and Sailors' monument. This massive shaft is the central and most notable decorative feature of the city. It is 285 feet high, including the bronze statue, and its base is ornamented with symbolic groups of statuary and reliefs in stone and bronze. It was designed by Bruno Schmitz and cost over $500,000. Four epochs in the history of the State are commemorated by the statues of George Rogers Clark, William Henry Harrison, James Whitcomb Riley and Oliver P. Morton, which are grouped about its base. The width of Washington street, 120 feet, and of the streets of the original plat, 80 and 90 feet, give space for the best possible display of architectural features. Plans were completed in 1918 by H. Van Buren Magonigle, architect, of New York, for an extensive educational centre on the former United States arsenal grounds of 76 acres, comprising 18 buildings, to include a stadium seating 29,000, an auditorium seating 9,000, high schools, industrial shops, etc., estimated to cost approximately $9,000,000.

Transportation.— Indianapolis is the centre of trade for the State. With the completion of the Indianapolis Southern Railway every county in the State except three, which are on the Ohio River, could be reached by railroad in less than one day's travel. Consolidations have placed most of the railroads in two systems. One of these, the Pennsylvania lines west of Pittsburgh, now operates the Madison and Jeffersonville lines, which reached the city in 1847, and the Vincennes line, completed in 1868; the Indiana Central to Columbus and the East, completed in 1853, and the Terre Haute and Richmond, later the Vandalia, completed in 1852, and now reaching Saint Louis; also a line to Chicago, partly over the Lake Erie and Western. The other, the Big Four system, operates the Bellefontaine road to Cleveland, completed in 1852; the Indianapolis and Cincinnati, which reached the city in 1850; the Indianapolis and Lafayette, of 1852, now reaching Chicago; the Indianapolis, Bloomington and Western to Peoria, finished in 1870, its eastern extension to Springfield, Ohio, completed about 15 years later; the Indianapolis and Saint Louis, completed in 1876. Through trains are also run to Benton Harbor, Mich., and to Louisville, over branches of these lines. The Cincinnati, Hamilton and Dayton Railroad Company operates the Cincinnati and Indianapolis Junction road, completed in 1868, and the Indianapolis, Decatur and Springfield road to Springfield, Ill. The Indianapolis, Cincinnati and Louisville operates a line to Chicago, which was completed about 1880. The Lake Erie and Western Railroad Company operates the old Peru and Indianapolis road, completed in 1854, and reaches Michigan City Toledo and Peoria.

These roads, which offer unusual facilities for handling both freight and passenger traffic, now are operated under 12 systems as follows: The Belt Railroad and Stock Yards Company; the Central Railroad of Indianapolis; the Chicago, Indianapolis and Louisville Railway Company; the Cincinnati, Hamilton & Dayton Railway Company; the Cincinnati, Indianapolis and Western Railway; the Cleveland, Cincinnati, Chicago and Saint Louis Railway; the Illinois Central Railroad; the Indianapolis Union Railway Company, which operates the "belt" or city switching system; the Lake Erie and Western; the Pennsylvania and Vandalia Lines; the Pittsburgh, Cincinnati, Chicago and Saint Louis Railway and the Vandalia Railroad Company.

The construction of the system of interurban roads began about 1890 with the Broad Ripple line, now a suburban line owned by the Union Traction Company of Indiana. The next to be constructed was the Indianapolis and Columbus line in 1900, now reaching Columbus. This line now is known as the Indianapolis, Columbus and Southern, has been extended to Louisville, Ky., and is operated by the lessees, the Interstate Public Service Company. It was followed quickly by the Indianapolis and Eastern, which now connects with Columbus, Ohio, and other eastern points. This line was extended to Terre Haute, and now is known as the Terre Haute, Indianapolis and Eastern. The Union Traction Company of Indiana entered the city from its centre in Anderson in 1901 and in 1903 completed a line north to Logansport, Tipton, and Kokomo, and other northern points. Lines entering the city in 1903 were the Indianapolis and Martinsville, the Indianapolis and Plainfield and the Indianapolis and Northern, extending to Crawfordsville and Lafayette. The Indianapolis and Cincinnati Traction line was completed east to Rushville in 1905 and since that time the line has been extended to Connersville. The right-of-way has been purchased to extend this line through to Cincinnati. This company also operates another line extending from Indianapolis to Shelbyville and Greensburg. The steam railroads are served within the city by the Union Railway Company owning the Union passenger station and the belt railway for facilitating the transfer of freight. The interurban electric roads are in like manner served by the Indianapolis Terminal and Traction Company owning a large terminal station and belt lines for passenger and freight business.

Manufactures.— During the brief natural gas era in Indiana, Indianapolis benefited largely by the cheap fuel. Since the failure of the gas supply the superior shipping facilities of the city and cheap coal fuel have attracted many more manufactories, and more than 160 industries are carried on in about 2,000 establishments. According to United States statistics covering business conditions in the city during 1916 the capital invested in 887 manufacturing establishments was $87,724,000, or an average capital of $99,000. The cost of the material used in all of the establishments during the year was $91,432,000, or an average cost of $98,000. The value of products manufactured in the city during 1916 was $140,346,000 or an average per establishment of $158,000. The number of employees was given as 37,956; the number of proprietors and firm members, 554, and the number of horsepower in operation, 65,266. Among the most important industries are slaughtering and meat packing; pharmaceutical and biological products; iron work; automobiles and accessories; carriages and wagons and material therefor; iron work of all kinds; furniture; malt liquors; printing and bookbinding; clothing; veneers; saws and lumber and lumber mill products.

Finances and Banking.— The assessed valuation of the city in 1870 was $24,656,460. In 1891 at the beginning of the era of public improvements it was $93,595,930, and in 1915 it

had increased to $244,217,280. The tax rate for State, county, township, city and school purposes was $2.53 in 1915. The net public debt was $4,602,500. The city's expenses for 1915, including money spent for track elevation and flood prevention, were $4,390,484.29. The postal receipts for 1915 were $1,631,795.52. The value of imports for 1915 was $535,821 and the total customs receipts were $262,603.57. The city has a total of 27 national banks, State banks and trust companies with total resources amounting to $111,823,921.44. It has six national banks with capital and surplus amounting to $9,700,000; 12 State banks with capital and surplus amounting to $606,900, and 9 trust companies with a capital and surplus of $6,000,000, the total capital and surplus of these institutions being $16,403,554. The deposits in the national and State banks aggregated in 1918 $50,000,000, while the savings deposited with trust companies amount to $22,904,453.60. There are about 90 building, loan and savings associations in various stages of progress and liquidation.

Churches.— Indianapolis is the seat of a Roman Catholic bishop, with an auxiliary bishop, and of an Episcopal bishop. Including missions there are 17 Roman Catholic churches in the city, 52 Methodist, 20 Presbyterian, 7 Episcopal, 54 Baptist, 5 Congregational, 9 Lutheran, 20 Christian, 4 German Evangelical, 3 Evangelical Association, 3 Friends, 3 United Presbyterian, 5 German Reformed and 71 of other denominations. There are 7 Hebrew congregations.

Charities.— In the city there are 15 hospitals, State, county, college, church, charitable and private, 4 homes for the aged, 10 industrial schools and orphan asylums, 4 homes for women and girls, more than 60 organized charitable and relief societies, and such institutions as the Red Cross, Y. M. C. A., Y. W. C. A., Friendly Inn, Humane Society, Day Nursery. The township trustee is a source of official relief. The charities of the city are efficiently administered, as a result of co-operation between organizations largely brought about through the efforts of Rev. Oscar C. McCulloch. In 1894 a plan of relief for the unemployed, whereby over 5,000 people were provided with the necessaries of life throughout winter without pauperizing influences resulting, became widely known as the "Indianapolis Plan of Relief." The plan was devised and carried out on behalf of the people of the city by a Commercial Club committee composed of Hugh H. Hanna, Col. Eli Lilly and William Fortune. In 1918 a fund of approximately $3,000,000 was raised by voluntary contributions for purposes of war relief and local charities, to be disbursed under the authority of the War Chest Board of Indianapolis. This board in 1918 undertook with the assistance of experts to reorganize the philanthropic work of the community under plans for centralized direction.

Education.— There are 80 public school buildings, including 3 high schools, one giving manual training, in which about 1,000 teachers are employed, with a total enrolment of about 45,000 pupils; 28 Catholic schools, 2 Lutheran schools, 25 private schools and academies, besides the schools in connection with institutions. The city is the home of several institutions of importance, Butler College, supported by the Christian Church, and the Indian University School of Medicine being among these. Other important schools are the Benjamin Harrison Law School, the Indiana Law School, the Indiana Dental College, and a large number of business, music and art schools. In addition there are several girls' schools supported by private funds or by religious denominations. Free kindergartens are operated under the Free Kindergarten Association, and 51 kindergartens and a normal school are maintained largely from public funds, besides a number of private kindergartens. The Art Association of Indianapolis maintains the John Herron Art Institute, including art gallery, school and museum. The Propylæum is a building erected by an association composed exclusively of women.

Libraries.—The most notable libraries are the public library with about 200,000 volumes, under the control of the board of school commissioners, and the State library with about 75,000 volumes. The State law library with 50,000 volumes, and agricultural and horticultural libraries in the State House, and the county library and bar association's library in the court-house may be noted. There are 12 branches of the public library and many small special libraries of schools and associations.

Newspapers and Literature.— Indianapolis has 7 daily papers, 23 weeklies, 38 monthlies, a total of 72 publications of all classes. The list of trade and class papers published in the city is particularly notable. Indianapolis is the home of many writers whose names are familiar to the public, notable among whom are James Whitcomb Riley, Booth Tarkington and Meredith Nicholson. In recent years Indianapolis has become an important western book-publishing centre.

Organizations.— The development of the city has been markedly influenced by organized work in various directions. There are a great number of literary, art and musical societies, and largely as a result of this activity there is a high standard of cultivation in such matters. This has had a notable influence in establishing in the social life of the city a standard of merit rather than determining the standing of the individual on questions of lineage or wealth. There are many social clubs, among the most notable being the University, Country, Woodstock, Dramatic, Contemporary and Woodruff Clubs, the Athæneum and the Männerchor, while the Columbia, Marion and Indiana Democratic Clubs are political organizations, established in comfortable homes. The Columbia Club building, located on the Circle, is one of the finest club-houses in the United States. The Commercial Club, now the Chamber of Commerce, with a membership of over 2,500, which owns as its home an eight-story office building, was a dominant force in the new era of progress and development which started in 1890, and devotes itself to the welfare of the city. The Board of Trade, an older organization with a membership of about 700, has also been active in this direction. The Red Cross has a membership of over 100,000 in Indianapolis, and expended more than $1,000,000 in 1917–18. Organizations of various kinds, commercial, trade, fraternal, social, literary, art, musical and miscellaneous, number over 1,000.

Government.—All city elective or appointive officers hold a four-year term of office. The administrative department is in the hands of the mayor and the boards and officials appointed by him. The city council consists of nine members, one being elected from each of the six councilmanic districts, and three at large. The council is composed of six members representing the party in power and three members of the next largest political party. The city clerk and police judge also are elected for four-year terms. The mayor's appointees are the corporation counsel, the city controller, the chief of police, the fire chief, three members of the board of public works, the three members of the board of public safety, the four members of the board of park commissioners, and four members of the city board of health. Other city officials, serving in departments subsidiary to those set forth above, are appointed by the mayor through the boards having the supervision of these departments. The board of school commissioners consists of five members elected by popular vote. The board is non-partisan, women being eligible to membership. The affairs of the school city are separate from those of the municipality proper, the board having control over its finances, which are provided by special tax levies under State law. Notable improvements in methods of municipal administration are in progress, as a result of a survey and recommendations of the New York Bureau of Municipal Research, made under the direction of the Chamber of Commerce in 1917 and the establishment by the Chamber of a Municipal Bureau in 1918.

Population.— Beginning with two or three families in 1819 or 1820, Indianapolis has shown a steady and rapid growth, having a population of 1,085 in 1830; 2,698 in 1840; 8,091 in 1850; 18,611 in 1860; 48,244 in 1870; 75,056 in 1880; 105,436 in 1890; and 169,164 in 1900. Since 1900 the increase in population has been still more rapid, the census of 1910 showing a population of 233,650, making an increase of 38.1 per cent over the figures given in the last official enumeration. The population in 1916 was estimated as 285,000; in 1918 at more than 300,000. In 1890 Indianapolis was 26th in population, and in 1920 it was 21st in the United States with a population of 314,194.

History.— The first settler, George Pogue, arrived in March of 1819 or 1820. The legislature of Indiana, meeting at Corydon, by committee selected, in 1820, the site for a State capital, and named it Indianapolis, 6 Jan. 1821. Another committee laid out the plat. Lots were slowly sold for several years, and the government was actually removed to the new capital in 1824, the first session of the legislature being held there in 1825. The first State House, modeled after the Parthenon, was completed in 1835. A town government was instituted in 1832 under three trustees, a town council was established in 1838, and a city government under mayor and council in 1847. The present metropolitan form of government, with the mayor as the responsible administrative officer and the council as the legislative branch, was adopted in 1891. A volunteer fire department was formed in 1826, which had much help from the State when the capitol building was completed. The first fire chief was appointed in 1853, and the department was changed to a corps of paid men in 1859. The police department was first established in 1854. The new town began to support a newspaper in January 1822, and a church in 1823. The first railroad reached the city in 1847, and several others were completed in the next four years. Their effect upon the town is seen in the large increase in population. The State capital was the centre of great activity during the War, and there was great expansion in business and manufactures as well as increase in population, most of which was retained. The city did its full share in raising regiments for the War, and is said to have expended a million dollars in contributions, bounties, and war expenses. Camp Morton, on its outskirts, was first a camp for training soldiers, and later for prisoners of war. The free school system now cited as a model by educational experts, was begun in 1853 with the accumulations of several years of special taxation spent in buildings and grounds. The Citizens' Street Railway charter was granted 18 Jan. 1864. The slaughtering and packing business, now so large a factor in the city's trade, began its great expansion in the same year. Public improvements were but few in number until the adoption of the new charter in 1891.

Indianapolis has numbered among her prominent citizens Benjamin Harrison, Thomas A. Hendricks, Charles W. Fairbanks, Thomas R. Marshall and others high in the affairs of the government.

WILLIAM FORTUNE,
President Indianapolis Chamber of Commerce.

INDIANOLA, Iowa, city and county-seat of Warren County, 18 miles south of Des Moines, on the Chicago, Burlington and Quincy and the Chicago, Rock Island and Pacific railroads. A large and increasing trade in grain, butter, eggs, fruit, live stock and garden products is carried on. The Simpson Methodist Episcopal College was established here in 1867. The electric light plant and waterworks are owned by the city. Pop. (1920) 3,628.

INDIANS, American. Columbus, when he discovered America, believed he had reached a part of Asia or of India, and in a letter of February 1493 wrote of "the *Indians* (in Spanish, *Indios*) I have with me." Thus the aborigines of the New World came to be called "Indians" (French *Indiens,* German *Indianer,* etc.), or, to avoid confusion with the natives of India, "American Indians," for which rather cumbrous term the word "Amerinds," susceptible of many modifications by means of prefix and suffix, and easily adaptable to the exigencies of modern European and other civilized languages, has been suggested by an eminent American lexicographer and is used more or less by a number of anthropologists and other writers. The word "American," originally applied to the Indians, is still somewhat in use, and Dr. D. G. Brinton styled his comprehensive sketch published in 1891, 'The American Race'; but its employment to designate the white population of the continent seems to bar its ethnological application to the aborigines without some qualifying term. By some writers the Indians are called the "Red Race," and, more popularly, "Redskins" (in French *Peaux-Rouges,* in German *Rothäute*), or "Redmen," terms of no exact somatic significance. A few American

and many European ethnologists continue to separate the peoples who created the civilizations of Mexico, Central America, Peru, etc., from the Indians, while others, exclude the Eskimo, and others, again, the "Mound-Builders." But somatic, cultural and linguistic evidence justifies the conclusions of Powell and Brinton in using the term "American Indians" to include not only the aborigines now existing, or known to have existed since the discovery, but also all the pre-Columbian peoples of America concerning whom we have little data — the most divergent are no more than sub-varieties of American man. This unity is the great ethnic phenomenon of American aboriginal history. The study of Indian languages, archæological remains, arts and industries, games, social and religious institutions, mythology and folk-lore indicates a general psychic unity, while the somatic diversities do not transcend those observable in the other great races of mankind. Whether one investigates, as McGee has so admirably done, the Seri of the Gulf of California, who represent about the lowest type of savage culture on the North American continent, or the Mayas of Yucatan, whose approach to a phonetic system of writing touches the high-water mark of Amerindian achievement, one receives the same impression: that it is a question not of very recent civilized or semi-barbaric intruders from Asia or from Europe, but of a race (whatever their remoter origins may be) who have dwelt for ages in an American environment, which has shaped them into the peoples met with by the whites at the time of Columbus' discovery. The limited effect of the "discovery" of the Norsemen may be held to discount any "discoveries" by Europeans before them; while, on the other hand, the American-Asiatic contact revealed by the investigations of the Jesup North Pacific expedition is as much American as Asiatic, and the "Bering Sea" culture is a local phenomenon no more fundamentally indigenous to the Old World than to the New. The arguments in favor of a trans-Pacific Malayo-Polynesian influence upon primitive America are no stronger than those that can be adduced to support the contrary opinion. The culture of the "Mound-Builders" does not in any way transcend the possibilities of what the American Indian was and is yet capable of, nor is it necessary to assume the presence of foreign culture-elements to explain the civilization of Mexico, Yucatan, Colombia and Peru. Since very primitive times America has been essentially the "ethnic island" of Brinton, Keane and other investigators. The impress of America has been upon the aborigines so long that physically, socially, linguistically they have been "Americanized" in so marked a fashion that their right to be considered one of the "races" of mankind is not to be dismissed without cause. To group them merely as a branch of the Mongolian, or, again, of the Malay "race," is to obscure many points of great importance in the prehistory of America or to ignore them altogether. The American Indian is in too many respects a modified (and anciently so) variety of mankind to be thought of as expressing in any serious degree the type of the Mongolian or the Malay.

Language and Culture.— The ethnic isolation of the American race has already been noticed. The apparent independence of the culture-centres of North and South America is another interesting fact. With the exception of a few possible traces of the presence of tribes of Arawak lineage in ancient Florida and the spread of art-*motifs* of the Caribbean type over a portion of the adjacent Gulf region, no direct evidence of the influence of South America upon North American culture is forthcoming. The independent origin of Mexican and Peruvian civilizations seems certain, and convincing proofs of the community of origin of Peruvian and Chibchan and even of Mexican and Mayan are lacking. The possibility of inter-cultural relations having once existed is, however, not to be denied. The Pacific coast, from the Gulf of California to the Argentine and Chile, has been a nursery of culture just as the Mediterranean area was for the Eurafrican peoples. There has been a Mexico and a "greater Mexico," a Peru and a "greater Peru," while the Mayas and the Chibchas have also had their extensive spheres of influence. To the Pueblo culture north of Mexico corresponds the Calchaqui culture south of Peru. On the northern borders of Mexico still lie the savage Seri and Yaqui, and the culture areas of Colombia and Peru have also their primitive frontages — and this was so in the time of the ancient Montezumas and the Incas. This juxtaposition of civilization and savagery is one of the characteristic facts of American ethnology, as it was once likewise of the history of the Mediterranean area in the Old World. In both areas we meet with a large number of peoples who rose above savagery, but, for some reason or other, failed to develop high stages of culture. That the more material evidences of civilization should be so confined to the Pacific coast is, to some writers, a significant fact suggestive of Asiatic relations; but the intellectual power of such Atlantic peoples as the Iroquois and some of the Muskhogean tribes of North America, and the moderate but distinct progress made by a few of the Brazilian tribes of the Atlantic area relieve us from any such theory, environment and historical incident in America quite sufficing to account for the phenomena involved. (See ETHNOLOGY). Certain other resemblances and contrasts in the various aspects of aboriginal culture in America merit attention here. At the extreme north of the continent, one stock, the Eskimo, with closely related forms of speech, kindred mythology and folk-lore, similar customs and social institutions, etc., extends in a narrow line from east to west, even overflowing into Asia, while at the extreme south (much less extensive) the Fuegians, numbering altogether less than 10,000, are divided into three distinct linguistic stocks (Yahgans, Onas, Alikulufs). Eastern and northern North America and the corresponding regions in South America are areas of wide distributions of single stock. The Pacific Coast of America, as compared with the Atlantic, is a place where, in diverse spots, languages seem to pullulate. This region (including the narrow limits of Mexico and Central America) contained probably more independent tongues than all the rest of the continent. Indeed, within the present bounds of the State of California alone 22 such tongues are found, with several others in Nevada, and in Prof. Cyrus Thomas' list of the stocks of Mexico and Central America, made in 1902, nearly 30 are recognized.

The multiplicity of languages in primitive America has called forth explanatory theories of various sorts, among them Horatio Hale's suggestion of the origin of linguistic diversity through the spontaneous language activity of the child. As Gatschet has noted, the very existence of such a multitude of tongues all over America is proof that neither in ancient nor in later times has this continent been the scene, on a vast scale, of the suppression and extermination of peoples one by the other, which have been characteristic features of Old World history. In spite of the common belief to the contrary, mutual destruction was probably never so rife as when the coming of the white man introduced new means of warfare, and, crowding the natives for subsistence, led them to attack each other more effectively. The recent studies of Dixon and Kroeber in California have strengthened the view of a certain parallelism of language and culture.

That some culture-elements, however, have spread from tribe to tribe is shown by the distribution of certain inventions discussed by Mason, the northward movement of such plants as maize, the use of tobacco, the transmission of many themes and incidents of myths and legends (as demonstrated by Boas), the modes of occurrence of certain art-forms, etc. Interminglings of culture of a more or less local, though often of an extensive, character, have taken place in the Bering Sea area, in the Columbia River region, in the habitat of the Pueblo Indians of New Mexico and Arizona, in the southeastern part of the United States, in the Isthmian region of Central America, in Ecuador, in the Pampean country of the Argentine, etc.— larger and more significant intermixtures have, perhaps, taken place in earlier times in Mexico, the Mayan country, Colombia and Peru. A number of the borrowed culture-elements may be explained as the result of trade and commerce, by means of which useful or artistic objects, food, plants, etc., were easily conveyed long distances under primitive conditions. The widespread custom of adoption would also account for not a few instances of alien culture-grafts. So, too, with the exogamic marriage, when the women are culture-bearers. Where language-mixture has taken place it is more or less easily detectable in most American Indian stocks and tongues. When families of the same stock possess, in the one case (Algonkian), dialects which differ as much as Micmac and Blackfoot, in the other (Iroquoian), as much as Cherokee and Mohawk, we are justified in looking for culture-differences as well in such widely separated peoples. Doubtless the results of careful somatological, sociological and other investigations of the various tribes of American aborigines will furnish us ultimately with diverse ways of classifying them. At present, however, the most serviceable classification is a linguistic one, the result of the labors of Major J. W. Powell and the Bureau of American Ethnology, supplemented by the work of Dr. D. G. Brinton.

Linguistic Stocks.— The Bureau of American Ethnology has issued the Powell map showing the extent of the 58 linguistic stocks north of the Mexican boundary line; that is, of families or forms of speech, so independent of one another as to be catalogued as distinct stocks; apparently no more closely related than the Aryan and the Semitic families of the Old World. For South America no such authoritative map is extant. The exact number of such linguistic stocks in America has not yet been determined with certainty, but the following list probably represents the best view of the matter to-day:

1. Adaizan (Louisiana)
2. Algonkian (northeast North America)
3. Alikulufan (Tierra del Fuego)
4. Andaquian (Colombia)
5. Arauan (northwest Brazil)
6. Araucanian or Aucan (Chile)
7. Arawakan (Central and N. E. South America)
8. Atacameñan (S. Bolivia)
9. Athapascan (N. W. Canada, etc.)
10. Attacapan (Louisiana)
11. Aymaran (S. Peru, N. Bolivia)
12. Barbacoan (S. Colombia)
13. Beothukan (Newfoundland)
14. Betoyan (Colombia-Venezuela)
15. Caddoan (Texas)
16. Calchaquian or Catamarcñan (N. Bolivia)
17. Canichanan or Canisianan (N. Bolivia)
18. Carajan (S. Brazil)
19. Cariban (N. E. South America)
20. Cayubaban (N. Bolivia)
21. Charruan (N. E. Argentine)
22. Chetimachan (Louisiana)
23. Chiapanecan (Central America)
24. Chibchan (Colombia and Isthmian region)
25. Chimakuan (Washington)
26. Chimarikan (California)
27. Chinantecan (Oaxaca, Mexico)
28. Chinookan (Washington)
29. Chiquitan (N. Bolivia)
30. Chocoan (N. W. Colombia and Isthmus)
31. Chumashan (California)
32. Churoyan (Colombia-Venezuela)
33. Coahuiltecan (Mexico-Texas, mouth of Rio Grande)
34. Coconucan (S. Colombia)
35. Copehan (California)
36. Costanoan (California)
37. Cunan (Isthmus of Panama)
38. Doraskean or Changuinan (Panama and Nicaragua)
39. Eskimoan (Northern fringe of North America)
40. Esselenian (California)
41. Guaniban (Venezuela)
42. Guaraunian (Venezuela)
43. Guaycuruan (Gran Chaco, Paraguay-Bolivia)
44. Huavean (Isthmus of Tehuantepec)
45. Iroquoian (Ontario-Erie region, with offshoot in S. E. United States)
46. Itonaman (Bolivia)
47. Jivaroan (Peru, Ecuador)
48. Kalapooian (Oregon)
49. Karankawan (Texas)
50. Kechuan or Quechuan (Peru)
51. Keresan (New Mexico, Pueblos)
52. Kiowan (Nebraska-Wyoming)
53. Kitunahan (S. E. British Columbia, N. Idaho)
54. Koloschan (Alaska)
55. Kulanapan (California)
56. Kusan (Oregon
57. Laman (Peru)
58. Lencan (Central America)
59. Lulean (Gran Chaco)
60. Lutuamian (Oregon)
61. Mainan (Ecuador, N. W. Brazil)
62. Mariposan (California)
63. Matacoan (Gran Chaco)
64. Matagalpan (Nicaragua)
65. Mayan (Yucatan, Chiapas, Guatemala, etc.)
66. Mocoan (Colombia)
67. Moquelumnian (California)
68. Mosateñan (Bolivia)
69. Moviman (Bolivia)
70. Muskhogean (S. E. United States)
71. Natchezan (Louisiana)
72. Onan (Tierra del Fuego)
73. Otomian (Central Mexico)
74. Otomacan (Venezuela-Colombia)
75. Palaihnihan (California)
76. Paniquitan (Colombia)
77. Panoan (Peru)
78. Payaguan (Gran Chaco)
79. Payan (Honduras)
80. Peban (Peru)
81. Piman (S. Arizona, N. W. Mexico)
82. Piaroan (Colombia-Venezuela)
83. Puinavan (Colombia-Venezuela)
84. Pujunan (California)
85. Puquinan (Peru)
86. Quoratean (California)
87. Salivan (Colombia-Venezuela)
88. Salinan (California)
89. Salishan (British Columbia, etc., to the south)
90. Samucuan (S. Bolivia)
91. Sastean (California)
92. Serian (N. W. Mexico)
93. Shahaptian (Oregon-Idaho)
94. Shoshonean or Uto-Aztecan
95. Siouan (Carolinas and Missouri Valley)
96. Skittagetan (Q. Charlotte Is.)
97. Subtiaban (Nicaragua)
98. Tacanan (Bolivia)
99. Takilman (Oregon)

100. Tañoan (New Mexico, Pueblos)
101. Tapuyan (S. Central Brazil)
102. Tarascan (Michoacan, Mexico)
103. Tequistlatecan (Oaxaca, Mexico)
104. Ticunan (N. W. Brazil)
105. Timotean (Venezuela)
106. Timuquanan (Florida)
107. Tonikan (Louisiana-Mississippi)
108. Tonkawan (N. W. Texas)
109. Totonacan (Vera Cruz, Mexico)
110. Tsimshian (British Columbia)
111. Tsonekan (Patagonia)
112. Tupian (E. Central Brazil)
113. Uchean (Georgia)
114. Ulvan (Nicaragua)
115. Waiilatpuan (Oregon)
116. Wakashan or Kwakiutl-Nootka (British Columbia)
117. Washoan (Nevada-California)
118. Weitspekan (California)
119. Wishoskan (California)
120. Xicaquean (Honduras)
121. Xincan (Guatemala)
122. Yahganan (Tierra del Fuego)
123. Yakonan (Oregon)
124. Yanan (California)
125. Yaruran (Venezuela)
126. Yukian (California)
127. Yuman (Lower California, Arizona)
128. Yucan (Peru)
129. Yurucarean (Bolivia)
130. Zaparoan (N. W. Brazil)
131. Zapotecan (S. E. Mexico)
132. Zoquean (S. E. Mexico)
133. Zunian (New Mexico)

Of the stocks enumerated, 51 belong to South America and 56 to North America north of Mexico. The status of investigation is such that the number assigned to South America is approximate only, and may ultimately be considerably increased or reduced. Some stocks, like the Adaizan, Beothukan (exterminated by whites), Chetimachan, and a few of the minor stocks in South America, are extinct or nearly so. A goodly number — including, for example, many of the stocks on the northwest Pacific Coast, the Texas-Louisiana country, parts of Central America and the Pacific region of South America — were or are of limited area; others, like the Eskimoan, Athapascan, Algonkian, Siouan, Shoshonean, Arawakan, Cariban, Tupian, etc., are noteworthy by reason of the extent of their domain. Some, like the Kootenay, consist of practically a single language, while others, like the Algonkian, Siouan, Athapascan, Salishan, Aztecan, Mayan, Arawakan, Tupian, Cariban, etc., have developed numerous dialects, sometimes only remotely resembling the mother tongue. Doubtless, with the perfection of linguistic research, some changes will be made in the list of stocks or perhaps a method of groups may be devised in which stocks showing certain resemblances other than those of a lexical nature may be classed together. The studies of Dixon and Kroeber indicate the possibility of this for the numerous Californian stocks, and a similar result may be predicted for certain other regions of the continent. As said, all the American Indian stocks are far from being of the same significance, many of them having hardly any historical importance. A few words about some of the most typical and most important must suffice here.

North American Stocks.— The Eskimoan stock is noteworthy by reason of being the first of all the aboriginal peoples of America to be visited by representatives of European culture — the Norsemen in the 10th century, etc. It is also the only primitive people who, unaided by civilized races, occupy a portion of both hemispheres, for the Eskimo stretch from Labrador to a considerable distance within the borders of northeastern Asia. They illustrate the victory of man over a difficult environment, for they are a merry and sociable people in spite of the inclement and depressing character of their Arctic surroundings. They have also a marked sense of humor, as the institution of nith-song, or settlement of disputes by public judgment of the comparative merits of the two parties in competitive singing would indicate — the themes of the singing being the dispute and sarcasm at the expense of the opponent. The Eskimo are also very skilful carvers and engravers of ivory, their spirited drawings of animals, etc., resembling in marked fashion the similar art-products of prehistoric man of the French river-drift, a likeness which has induced some authorities (Dawkins, De Mortillet) to assume a racial connection between these two peoples.' Mason has recently suggested that these drawings owe a good deal to the contact with Europeans (introduction of iron tools, etc.), but Boas considers that their close resemblance to the bark and rock pictographs of the Indians forbids the conclusion that these drawings are of other than native origin. The unity of language and (to a considerable degree) of custom, mythology, etc., among the various Eskimo tribes is remarkable when one remembers the extent of their distribution. The use of the Eskimo dog with the sledge, the kayak, the harpoon, the snow-house (iglu) and the invention of many mechanical devices, show them to be gifted with native intelligence.

The Athapascan stock is notable for the contrasts in culture and diversities of culture-capacity presented by its members. Some of the Athapascan peoples of northwestern Canada and Alaska are among the lowest types of American man, and a few of them have hardly yet come to knowledge of the white man, the advent of the fur-trader being, according to J. M. Bell, a matter of the last few years in part of their domain. To this stock belong also the Apaches, once the terror of the civilization of the Southwest, whose depredations, in earlier times, disturbed the peace of the native civilization of Old Mexico. It is fair to say, however, of them that individual Apaches (Dr. Montezuma, for example) show good capacity for adopting the chief elements of white American culture. Several small tribes of Athapascans are scattered through Washington, Oregon and California, the most noteworthy being the Hupa, on Trinity River, the "Romans of California," as they have been called. The Navaho, who have assimilated to a considerable extent the culture of the whites, were good agriculturists before the coming of the Spaniards, from whom they adopted the sheep, a fact which modified their environment and their response to it. The contrast between the rude tribes of the "Barren Grounds" of Canada and the Navaho of New Mexico and Arizona is, as Horatio Hale pointed out, one of the most remarkable instances of culture-change by process of environmental variation on record. The recent loan-word *Klondike* comes from an Athapascan dialect.

The Algonkian stock, members of which were found from Labrador to South Carolina, and from the confluence of the Ohio and Mississippi northwesterly to the foot of the Rocky Mountains and the borders of the domain of the Athapascans, is of interest for many reasons. The great area over which it is spread has brought members of this stock into contact with many other Indian peoples,— the Naskopi, Crees, and northern Ojibwa with the Eskimo; the Micmacs with the Eskimo and

1. Labrador Eskimo Woman. 2. Mexican of the coast. 3. Mexican of the highlands. 4. Yucatan Indian Woman. 5. Ecuador Indian. 6. Peruvian Indian. 7. Brazilian Indian (Ipurina). 8. Dakota (Sioux) Indian. 9, 10. Apache. 11. Bellacoola (N. W. Coast). 12, 13. Pueblo Indians (New Mexico). 14, 15. Indians of Zapoteca, Mexico. 16. Bororó. 17. Caraja. 18. Botocudo. 19. Umaua or Omagua (16-19 of Brazil). 20. Araucanian (Chile). 21, 22. Indians of Tierra del Fuego, with a child. 23. Patagonian.

100. Tañoan (New Mexico, Pueblos)
101. Tapuyan (S. Central Brazil)
102. Tarascan (Michoacan, Mexico)
103. Tequistlatecan (Oaxaca, Mexico)
104. Ticunan (N. W. Brazil)
105. Timotean (Venezuela)
106. Timuquanan (Florida)
107. Tonikan (Louisiana-Mississippi)
108. Tonkawan (N. W. Texas)
109. Totonacan (Vera Cruz, Mexico)
110. Tsimshian (British Columbia)
111. Tsonekan (Patagonia)
112. Tupian (E. Central Brazil)
113. Uchean (Georgia)
114. Ulvan (Nicaragua)
115. Waiilatpuan (Oregon)
116. Wakashan or Kwakiutl-Nootka (British Columbia)
117. Washoan (Nevada-California)
118. Weitspekan (California)
119. Wishoskan (California)
120. Xicaquean (Honduras)
121. Xincan (Guatemala)
122. Yahganan (Tierra del Fuego)
123. Yakonan (Oregon)
124. Yanan (California)
125. Yaruran (Venezuela)
126. Yukian (California)
127. Yuman (Lower California, Arizona)
128. Yucan (Peru)
129. Yuracarean (Bolivia)
130. Zaparoan (N. W. Brazil)
131. Zapotecan (S. E. Mexico)
132. Zoquean (S. E. Mexico)
133. Zuñian (New Mexico)

Of the stocks enumerated, 51 belong to South America and 56 to North America north of Mexico. The status of investigation is such that the number assigned to South America is approximate only, and may ultimately be considerably increased or reduced. Some stocks, like the Adaizan, Beothukan (exterminated by whites), Chetimachan, and a few of the minor stocks in South America, are extinct or nearly so. A goodly number — including, for example, many of the stocks on the northwest Pacific Coast, the Texas-Louisiana country, parts of Central America and the Pacific region of South America — were or are of limited area; others, like the Eskimoan, Athapascan, Algonkian, Siouan, Shoshonean, Arawakan, Cariban, Tupian, etc., are noteworthy by reason of the extent of their domain. [illegible]

[illegible] Arctic surroundings. They have also a marked sense of humor, as the institution of nith-song, or settlement of disputes by public judgment of the comparative merits of the two parties in competitive singing would indicate — the themes of the singing being the dispute and sarcasm at the expense of the opponent. The Eskimo are also very skilful carvers and engravers of ivory, their spirited drawings of animals, etc., resembling in marked fashion the similar art-products of prehistoric man of the French river-drift, a likeness which has induced some authorities (Dawkins, De Mortillet) to assume a racial connection between these two peoples. Mason has recently suggested that these drawings owe a good deal to the contact with Europeans (introduction of iron tools, etc.), but Boas considers that their close resemblance to the bark and rock pictographs of the Indians forbids the conclusion that these drawings are of other than native origin. The unity of language and (to a considerable degree) of custom, mythology, etc., among the various Eskimo tribes is remarkable when one remembers the extent of their distribution. The use of the Eskimo dog with the sledge, the kayak, the harpoon, the snow-house (iglu) and the invention of many mechanical devices, show them to be gifted with native intelligence.

The Athapascan stock is notable for the contrasts in culture and diversities of culture-capacity presented by its members. Some of the Athapascan peoples of northwestern Canada and Alaska are among the lowest types of American man, and a few of them have hardly yet come to knowledge of the white man, the advent of the fur-trader being, according to J. M. Bell, a matter of the last few years in part of their domain. To this stock belong also the Apaches, once the terror of the civilization of the Southwest, whose depredations in earlier times, disturbed the peace of the native civilization of old Mexico. It is fair to say, however, of them that individual Apaches (Dr. Montezuma, for example) show good capacity for adopting the chief elements of white American culture. The contrast between the rude tribes of the "Barren Grounds" of Canada and the Navaho of New Mexico and Arizona is, as Horatio Hale pointed out, one of the most remarkable instances of culture-change by process of environmental variation on record. The recent loan-word Klondike comes from an Athapascan dialect.

The Algonkian stock, members of which were found from Labrador to South Carolina, and from the confluence of the Ohio and Mississippi northwesterly to the foot of the Rocky Mountains and the borders of the domain of the Athapascans, is of interest for many reasons. The great area over which it is spread has brought members of this stock into contact with many other Indian peoples, — the Naskopi, Crees, and northern Ojibwa with the Eskimo; the Micmacs with the Eskimo and

1. Labrador Eskimo Woman. 2. Mexican of the coast. 3. Mexican of the highlands. 4. Yucatan Indian Woman. 5. Ecuador Indian. 6. Peruvian Indian. 7. Brazilian Indian (Ipurina). 8. Dakota (Sioux) Indian. 9, 10. Apache. 11. Bellacoola (N. W. Coast). 12, 13. Pueblo Indians (New Mexico). 14, 15. Indians of Zapoteca, Mexico. 16. Bororó. 17. Caraja. 18. Botocudo. 19. Umaua or Omagua (16-19 of Brazil). 20. Araucanian (Chile). 21, 22. Indians of Tierra del Fuego, with a child. 23. Patagonian.

Beothuk; the Ojibwa and related tribes of New England, New York and Pennsylvania, the Lenâpé of New Jersey, the Nanticokes, Powhatans, etc., of Maryland, Virginia and the Carolinas with the Iroquois (who, both north and south, form an *enclave* in the Algonkian territory); the western Ojibwa, etc., with the Siouan tribes in the upper Mississippi region, and in the southern Mississippi country the Illinois and kindred peoples with the Caddoan and other stocks; the Blackfoot in the extreme northwest of the Algonkian area with the Athapascan Sarcees and the Kootenay. The aberrant Cheyennes and Arapaho (recently studied by Kroeber) belong to the Algonkian stock. Another evidence of the importance of this stock is the fact that many other stocks and tribes are known to us by names of Algonkian origin: *Eskimo, Athapascan, Siouan,* and possibly also *Iroquoian* and *Muskhogean; Chipwyan, Assiniboin, Mohawk,* etc. Of all the Indian stocks of North America none have made a greater impression upon the whites (French and English) than the Algonkian. This is seen when we remember that Powhatan and Pocahontas, King Philip, Pontiac, Tecumseh, Black Hawk, etc., the Indians who have appealed most to our historians, novelists and dramatists, have all been of Algonkian lineage. This stock has also contributed to the vocabulary of spoken and written American-English some 140 words, of which many are hardly felt to be of Indian origin: *Carcajou, Caribou, Caucus, Chipmunk, Hickory, Hominy, Manito, Maskinonge, Menhaden, Moccasin, Moose, Mugwump, Opossum, Pappoose, Pemmican, Persimmon, Powwow, Pung, Raccoon, Sachem, Skunk, Squash, Squaw, Tammany, Terrapin, Toboggan, Tomahawk, Totem, Tump, Tuxedo,* etc. A people who have contributed to such a cosmopolitan tongue as English important words like *Caucus, Mugwump, Tammany* and *Totem,* deserve more than passing mention. Our civilization owes to them also more material things than these,—tobogganing and lacrosse, canoeing (in large measure) and numerous devices of agricultural and domestic industry adopted by the early colonists from the aborigines. From the Algonkian Indians the whites also learned how to make maple sugar and maple syrup.

The Iroquoian stocks are famous through the confederacy of the "Five (afterward Six) Nations" and the great "League of the Iroquois" (so sympathetically studied by Morgan). Their physical characteristics at the time of the war of 1861–65 were such that they exceeded the recruits of all other races (white included) in points of excellences demanded by military requirements. The high position occupied by woman among the Iroquois lifts them above many of their Amerindian kindred. The story of the Iroquoian statesman of the 16th century, Hiawatha, and his founding of the league that was to end all war and unite all the nations in one lasting bond of peace is a historical fact, which Longfellow's confusion of the Iroquoian patriot with the Algonkian demi-god Manabozho cannot altogether obscure. In political and social organization the Iroquoian tribes attained a position that was largely *sui generis.* The tale of their long struggle to preserve their independence against the whites will be found in Morgan and Parkman, while the 'Jesuit Relations' contain their reaction to the efforts of the missionaries to convert them to the Christian faith, as well as the account of the fratricidal strife resulting in the extermination of the Hurons. The fame of the Iroquoian tribes (for example, Mohawks) as fierce warriors has caused the general public to neglect them in other respects. Through the researches of Horatio Hale and others it has been shown that the Cherokee of the Carolinas (recently so well investigated by Mooney) belong to the Iroquoian stock, together with several minor tribes in the south Atlantic region. This stock has produced a number of eminent men: Hiawatha, Red Jacket, Joseph Brant and Dr. Oronhyatekha (qq.v.), of the Independent Order of Foresters; J. N. B. Hewitt, of the Bureau of American Ethnology at Washington, is also of Iroquoian blood. Sequoia, the half-blood Cherokee, who invented the alphabet now in use by his people, deserves mention here likewise. As compared with the prominent part played by them in the French-English and colonial wars, and in the Revolutionary War, War of 1812, etc., the Iroquoian people left little impression upon the culture and the speech of the English in America,—the words from their language which have crept into our own have been originally place-names: *Chautauqua, Conestoga* (horse), *Saratoga* (trunk), etc. To the French of Canada they have given a few more words. In the place-names of the region about Lakes Ontario and Erie (Ontario, Niagara, Erie, Cataraqui, Oswego, Cayuga, Seneca, Onondaga, Tuscarora, Oneida, Ticonderoga, Tonawanda, Genesee, Ohio, etc.), the Iroquoian peoples are generously remembered, while their Cherokee kinsmen in the south have likewise left their impress upon the topographical nomenclature of the country. In both New York and Ontario, where considerable numbers of Iroquois still live, with no immediate danger of dying out, but particularly in the latter province on the Grand River Reserve, the pagan and Christianized Iroquois have existed side by side in the same community for so long a time as to make this phenomenon, the details of which have been pointed out by David Boyle, of great value to sociologists. See INDIANS, CANADIAN.

The Muskhogean stock (Choctaws, Chickasaws, Creeks, Seminoles, etc.), as their subsequent career in the "Civilized Nations" of the Indian Territory with the Cherokee has shown, are among the most gifted intellectually of the aborigines of America. Gatschet notes as characteristic of this stock: Their color-symbolism for peace and war, their totemic system, the use of the "black drink," the doctrine of the "Master of Life," sun-worship, mound-building (some regard this stock as having been one of the so-called "Mound-Builders"), the ceremony of the *busk,* etc. This stock has had many intertribal wars, and the Creeks and particularly the Seminoles of Florida are famous for their contests with the whites.

The Siouan stock (Crows, Mandans, Assiniboins, Hidatsa, Sioux, Winnebagos, Omaha, Tutelos, Catawbas, Biloxi, etc.), are noteworthy by reason of their migration from the Atlantic slope in the region of the Carolinas to the trans-Mississippian and Missouri country, where their culture was conditioned by the presence of the buffalo and the adoption (from the whites)

of the horse. Their wars with the surrounding tribes, particularly the Algonkian, and their subsequent numerous collisions with the whites (Minnesota massacre of 1862, the troubles in which Sitting Bull figured, etc.), are matter of history. The use of buffalo-skins made it possible for some of the Sioux tribes to develop pictography to a high degree. The researches of J. Owen Dorsey and Miss Alice Fletcher have shown the Omaha in particular to be gifted with a religio-social consciousness of a marked character, reflected in their name-giving and the ceremonies associated with the passage from childhood to manhood, in which individuality is much emphasized. That their capacity for producing men of ability is not confined to those of the primitive type (Sitting Bull) is indicated by the way in which individual members of this stock (Dr. Eastman, La Flesche, the collaborator of Dorsey, etc.), have responded to the stimuli of modern culture. The Dakotan federation is well remembered by the names of the twin States of the Northwest; Minnesota, Nebraska, etc., are terms of Siouan origin; while the minor place-nomenclature of the Northwestern States contains a multitude of names from the same source.

The Shahaptian stock is noteworthy on account of the Nez Percés and the famous chief Joseph, one of the most remarkable Indians of any age, whose "retreat" in 1877 has been compared to the celebrated march of the Ten Thousand of old.

The "Pueblo" Indians, as they are called from their village life, have risen in New Mexico and Arizona above the stage of savagery into a state of semi-civilization, representing the triumph of man over the adverse conditions of the desert and the inroads of fierce enemies of the lowest culture. Their relations to the so-called "Cliff-Dwellers" has been the subject of ethnological speculation. (See PUEBLO INDIANS). Diversity of culture among the Pueblos is not as great as that of speech. Besides the Moqui or Hopi, who belong to the Shoshonean stock, there are found in the Pueblos group three other distinct linguistic stocks, — Keresan, Tañoan and Zuñian. The Pueblos culture has apparently been developed independently in several local centres, and the studies of Bandelier, Hodge, Fewkes, Cushing, etc., have thrown much light on the origins and interrelations of stages of culture largely the reflex of environment.

The Shoshonean or Uto-Aztecan stock offers the most wonderful contrasts in its members of any Amerindian stock. Linguistic and other evidence appears to justify the conclusion that not only certain peoples of the Sonoran country (Cahitas, Coras, Tepehuanas, etc.), some of whom achieved a sort of half-civilization in contact with their more cultured neighbors, but the Bannacks, Shoshones and Utes (even the wretched "Root-diggers") are kith and kin with the ancient Aztecs upon whose civilization Cortes intruded, and the tribes of Nahuatl lineage who carried that culture more or less from central Mexico to beyond Lake Nicaragua. The change from the low type represented by the Utes to the high type of the old Mexicans may have been due in large measure to environment. Intermediate stages are represented by some of the Sonoran tribes. The Mexican or Aztec branch of this stock has furnished to English and other civilized languages a number of interesting and valuable words: *Axolotl, chocolate, coyote, cacao, tamato, ocelot, chilli, copal, chinampa, jalay,* etc. The Moqui group of the Pueblos Indians belong also to the Shoshonean stock.

The Mayan stock (Cakchiquels, Huastecs, Tzotzils, Kekchis, Quiché, Tzendals, Mayas, etc.), creators of the civilization destroyed by the Spaniards in Central America, left, besides graven monuments in large numbers, other evidences of their having invented a system of "writing," which is the nearest approach by any of the aboriginal peoples of America to a phonetic method of record,— the solution of the Mayan hieroglyphics is perhaps *the* question of American archæology. Their calendar-system, nagualism in religion, and the important rôle of women in religious and social functions, deserve especial notice. The explorations of the Peabody Museum (Cambridge) resulted in many new discoveries.

Central and South American Stocks.— The Chibchan stock, whose culture varied from that of the savage Aroacos of the mountains of Santa Marta to the civilization of the country about Bogota, represents a rise from barbarism independent of that to the south in Peru, etc. There is some reason to believe that the "gold-culture" of the Chiriqui country and allied remains in the same region to the borders of Nicaragua may be due to the Chibchan stock,— the Talamanca, Guaymi, and a few other dialects of Costa Rica, etc., show affinities with Chibchan tongues. Their use and working of gold were of a high order, but neither in architecture nor in pictography could they compare with the Peruvians, the Mexicans and the Mayas. They had a characteristic hero-legend of Bochica, and a tale of the great flood. The shrine of Lake Guatavita was a famous religious resort. Some of the famous "El Dorados" were in their territory. The Quechuan stock, which is best known through the civilization of the Incas, superimposed upon an older, wide-spread culture, represents but one phase of higher human activity in the Peruvian area. The extension of Quechuan language especially von Tschudi and Brinton agree in attributing not to the military achievements of this people, which antedated the coming of the Spaniards by only a few centuries, but to intellectual and culture influences millenniums old. The marks of their language can be traced from near the equator on the north to the Pampean tribes on the south. Common in the Peruvian area seem to have been a highly developed agriculture (stimulated, as in the southwestern United States, by the necessity for irrigation and artificial treatment of the soil),— maize, tobacco, potatoes, cotton, etc., the breeding of the llama and the paco, the making of pottery (useful and artistic), metal-working of a fine and ingenious sort, stone architecture more massive and imposing than artistically beautiful, or of the highest order as regards decorative art. The Inca form of government was never probably so far removed from the system common to most of the American stocks as some writers have believed. The Incasic conquest has caused the Peruvians to be styled the "Romans of America," but the analogy is misleading. Beyond the use of picture-writing and the employment of the quipu (knotted colored strings) for purposes of record, the Peruvians had not advanced, and the semi-phonetic system, like that of the Mayas, was not developed by them. Ancestor-worship and sun-worship (state religion) were professed by the Peruvians, but the most far-sighted of their thinkers touched almost upon monotheism. The hero-god of the Peruvians was the sea-born Viracocha, about whom centred a rich and imaginative mythology. The mixture of races in the production of ancient Peruvian culture is indicated by the diversity of cranial type among the skulls from the old burial grounds and mummy-caves. North of the Quechuas, on the coast about Trujillo, were the Yunca-Chimus, etc., whose civilization is represented by the ruins of Gran Chimu and other remains in the valley of Trujillo, which preceded the period of Inca domination. Southeast of the Quechuan culture was that of the Aymaras on the Andean table-lands. To them are usually assigned the ruins of Tiahuanaco, near Lake Titicaca, which in their completeness were probably the most imposing structures raised by the hand of aboriginal man in America,— in architecture they differ in several notable ways from the buildings of Inca origin. Dr. Uhle has very recently sought to show the "succession of cultures" at Pachacamac, Trujillo, and their relations to that of Tiahuanaco. The Peruvian tongues have furnished modern English, etc., many words: *guano, condor, alpaca, pampa, paco, llama, coca, quinine, jerked* (beef), *vicuña* etc.

In the northern part of the Argentine Republic (province of Jujuy, etc.) the architectural and archæological remains brought to light by recent investigators (Ambrosetti in particular) indicate the presence of a "civilization," — village life in a desert environment, offering striking analogies with the culture of the Pueblo Indians of Arizona and New Mexico. This Calchaqui culture is evidently much more than the mere reflex of Quechuan-Aymaran conquest which it was formerly considered to be. Its origin and growth, however, remain to be clearly demonstraed.

The Araucanian stock, whose language has been studied by Lenz, are famous for their long resistance to the Spanish arms (the story of the "conquest" has been written by Guevara), part of which gave rise to De Ercilla's epic of 'La Araucana' (q.v.). To the Araucanian stock belong tribes on both sides of the Chilean Andes and a number of the nomadic peoples of the Pampas, where they seem to be intruders rather than aborigines. Chilean Spanish has borrowed many expressive terms from Araucanian.

The Patagonians, Tzoneк, or Tehuelche, have been famous since the time of Pigafetta as "giants" (many of them exceed six feet and some are said to reach seven). To them belongs the "Setebos" of Shakespeare's 'Tempest.'

The Tapuyan stock of Brazil is looked upon by some authorities as the oldest people of the continent — some would affiliate with them the Fuegians, in this respect — representing a race once inhabiting a great part of South America. The man of the caves of Lagoa Santa and the man of the remarkable *sambaquis* or shell-heaps of the Brazilian coast are by many authorities considered to have been related to the Tapuyans. Characteristic modern Tapuyans are the Botocudos, so called from the labret they wear in the lower lip. According to Ehrenreich, some of these ancient men of Brazil show affinities with prehistoric man of eastern Europe.

The Tupian stock (or Tupi-Guaranis, as they are also called), whose language was much used by the missionaries for general intercourse with the natives and is the basis of the *ligoa geral,* or "common language" of the region of the Amazons, was perhaps the highest in culture of the Brazilian tribes, having the elements of agriculture, village life, pottery (well developed and rather artistic), urn-burial, etc., but nothing beyond the Stone Age. Intermixture with both whites and negroes has taken place in the Tupi area, and the rich and imaginative tales of animals, etc., belonging to Tupi mythology have thus been given a wider extension, while negro and white influences have made themselves felt, both on the language and the literature of these people. According to Hartt, the Tupi language has influenced the Portuguese of Brazil quite as much as has the latter the former. Tupi-Guarani speech has furnished to the various European tongues a considerable number of words—to English, *ipecacuanha, jaguar, tapioca, tapir, toucan,* etc.

The Cariban stock were long famous for their cannibalism (the word *cannibal* is a corruption of one of their ethnic names), real and attributive, and their skill in making and using canoes. The shaman, or medicine-man, had great power among them, and they practised the curious and remarkable custom of the *couvade.* Rock-inscriptions and pile-dwellings are found in their territory. Some of them have been reduced to sad straits by the contact of the whites, but some of the Venezuelan tribes of this stock are still good, typical representatives of the American Indian.

The Arawakan stock, through its representatives (the Bahamian Lucayans, the natives of Haiti, Porto Rico, Cuba, etc.), was the first of the aboriginal peoples of the New World (exclusive of Greenland and Labrador) to come into contact with the white race, and likewise the first to come under its devastating influence. Many of the tribes of this stock were of a mild and gentle disposition, good agriculturalists, pottery-makers, workers in stone, wood and gold, and excellent canoe-men (the word canoe comes from an Arawak dialect). They were users of cotton, and to them we owe the first Indian invention adopted by the whites (*hammock,* both name and thing are Arawak). From the Arawaks, too, the Spaniards first learned the use of tobacco. Like the Caribs they practised the *couvade.* The name of the stock is said to mean "flour-eaters," on account of their use of cassava, which has also passed over to the white. The Arawak and Carib stocks have furnished to English and to the other civilized languages of Europe a large number of important words, the exact ethnic distribution of which is not easy to determine with exactness: *Agouti, anotto* (and French *roucouyenne*), *barbecue, cacique, caiman, cannibal, canoe, cassava, colibri, hammock, hurricane, iguana, macaw, maize, manati, potato, tobacco,* etc. And with these names has gone the use of many of the things indicated and made known for the first time to Europeans. The debt of the Spanish and Portuguese settlers of South America and the West Indies is in these respects very great, for, nat-

urally new fruits, plants, trees, etc., and many of their products came to be known by their aboriginal names or by corruptions of them. Thus a number of "balms" and "balsams" and other medicinal products retain in the pharmacopœia names of American Indian origin — *copaiba, tolu,* etc. Timber-trees, ornamental and dye-woods, have also largely kept their native appellations throughout Central and South America — the list would run into the hundreds. Large also is the catalogue of birds and other animals bearing Indian names.

Original Habitats.— The question of the original habitats of the important aboriginal stocks is one of the most interesting in American ethnology and archæology. The researches of Rink and Boas in particular seem to have demonstrated that the primitive home of the Eskimo was in the region west of Hudson Bay, whence they spread northward and westward to Alaska, etc., and eastward (north and south) to the Arctic islands, Greenland and Labrador. See ESKIMOS.

The earliest habitat of the Athapascans was in northwestern Canada, to the westward of the home of the Eskimo. From there they migrated over the lake country, across the Rockies to the southward, leaving colonies along the Pacific to northern California, and sending out, through Arizona and New Mexico to the borders of the Nahuatl territory, the important branches of the Apaches and Navaho — the raids of the Apaches often reaching far into Mexico.

The original habitat of the Algonkian stock was, as Brinton and Hale have assumed, "somewhere north of the Saint Lawrence and east of Lake Ontario," while that of the Iroquoian lay "between the lower Saint Lawrence and Hudson Bay." The final result of the migrations and wars of these two stocks was to leave the Iroquois of the Ontario-Erie country entirely surrounded by Algonkian tribes. From their primitive home the Algonkian sent out numerous branches west, south, southwest, etc., making the extent of territory covered by them very large, and bringing them into immediate contact with many other Indian tribes and with the white settlers over a vast area. The Iroquois (in the Cherokee and the kindred tribes of the south) had branches, which were so separated from their northern kin as to be long taken for non-Iroquoian peoples.

The Muskhogean stock, according to Gatschet, have been from time immemorial inhabitants of the country between the Appalachian Mountains, the Atlantic, the Gulf of Mexico and the Mississippi. The scene of their earliest development was in the neighborhood of the Mississippi, or possibly even beyond it.

The chief migrations of the Caddoan (Pawnee) peoples have taken place in historical times northward and southward from the Platte River, from which region they expelled in part the Siouan tribes, etc. If their own traditions are reliable, their primitive home lay farther to the south, on the Red River of Louisiana.

The primitive home of the Siouan stock (characteristic Plains Indians since the introduction of the horse) was eastward in the region of the Carolinas. This fact has been revealed by the study of the Tutelo and Catawba languages belonging to this eastern area, and by inspection of the traditions of the various Siouan tribes. The main bodies of Siouan migrants followed the Ohio and the Missouri far to the north and west; the Mandans, Assiniboins, etc., reaching to within the borders of Canada. Other minor bodies traveled to the southwest, their representatives still existing in the Biloxi, etc., of southeastern Mississippi. The Siouan tribes seem to have followed the buffalo in its retreat westward, and their migration from the Carolinas is of considerable sociological interest. At one time their trans-Mississippian habitat included practically all the territory between the Arkansas and the Saskatchewan from the great river to mid-Montana, with the Winnebagoes jutting out on Lake Michigan. Their forays and trade-excursions led some of them from time to time across the Rocky Mountains.

The original habitat of the Shoshonean or Uto-Aztecan stock, which embraces the Ute, the Sonoran and the Aztecan (Nahuatl) peoples, and has representatives from the north of Idaho to the Isthmus of Panama, was probably somewhere in the northwestern section of the United States. The primitive home of the Shoshonean section was "somewhere between the Rocky Mountains and the Great Lakes," and the traditions of the other two branches bring them from the far north, as compared with their present southern abode.

The Mayan stock, creators of the civilization of Central America, according to their own traditions, came from somewhere to the north — the position of the Huastecan branch of this stock north of Vera Cruz suggests that the Mayan emigrants from the home-land skirted along the Gulf of Mexico from some region considerably to the north.

The Arawakan stock (including the natives of the Bahamas and the Antilles, except the intrusive Caribs) had an extension in South America comparable only to that of the Algonkians and Athapascans in the northern half of the continent — from the high Paraguay to the Goajiran Peninsula in Venezuela, and in its greatest expansion from the Xingù to the Amazon and Orinoco. Its primitive habitat was in some part of the Brazilian interior, probably between the Xingù and the Paraguay, the general trend of their migrations having been northward. The Cariban stock, another very extensive people, who at the time of Columbus' discovery were to be found in the smaller West Indian islands, and the northern part of the continent from the Essiquibo in Guiana to about the Isthmus of Panama, came originally, as the presence of the Carib Bakairi on the Xingù indicates, from the high interior of Brazil, at the sources of the Xingù and Tapajos.

The Tupian stock was widely extended at the time of the discovery along the Atlantic Coast region from La Plata to the Amazon, with branches scattered along the Paraguay and the Madeira to the foot of the Andes. Their primitive home, Brinton, with reason, assumes to have been in the central highland country to the east of Bolivia. The general direction of the earliest migrations of this stock was therefore southward (down the Paraguay to the Atlantic), after which the Tupi branch followed the coast to the Amazon. The Tapuyan stock, who once occupied the region between the Xingù and the Atlantic Coast (from the latter they have been driven by the Tupis), are probably the oldest human residents of part of this

area, their tenure of the seacoast reaching far back into prehistoric times.

The Chibchan stock, to which was due the civilization of the Bogota region of Colombia, had their original habitat in the Andean highlands of central or southern Colombia, whence they wandered northwest into the Isthmus of Panama and northeastward up the Magdalena.

The Quechuan stock, authors of the most remarkable of South American civilizations, according to their own traditions spread from very small beginnings in the country about Lake Titicaca; but von Tschudi and Brinton, for linguistic reasons chiefly, find the primitive home of this people to have been in the extreme northwest of their characteristic area. The Aymara stock, which some authorities consider to have been a branch of, or perhaps an old member of the Quechuan, had its original habitat to the southeast of the latter. The relation of the Aymaran stock to that which produced the Calchaqui civilization of the northern Argentine is not clear.

Language and Writing.—Although the languages of the American aborigines constitute so many independent families of speech, the vocabularies of which are entirely divergent one from another, nearly all (if not all) of them possess certain general grammatical characteristics which justify us in classing them together as one great group of human tongues. Brinton enumerates as points of resemblance: Development of pronominal forms, fondness for generic particles and for verbs over nouns, and incorporation — the inclusion of subject or object (or both) in the verb, etc. Most American Indian tongues may be called "holophrastic," from the practice of compressing a whole "sentence" into a "word," the length of which is sometimes very remarkable. As an example may be cited the Micmac (Algonkian) *yăleoolemăktâwepokwŏse,* "I am walking about carrying a beautiful black umbrella over my head." This word, according to Rand, is derived from *pokwŏsŏn,* "an umbrella"; *măktāwāe,* "I am black"; *wolāe,* "I am beautiful"; *yălcā,* "I walk about." From the Kootenay language may be cited: *Nātltlămkinē,* "he carries the head in his hand" (*n,* verbal particle; *ātl,* "to carry"; *tlām,* composition form of *āaktlām,* "head"; *kin,* "to do anything with the hand"; *inē,* verbal); *hinūpqanāpinē,* "thou seest me" (*hin,* "thou," subject pronoun; *ūpqa,* "to see"; *āp,* "me," objective pronoun; *inē,* verbal). As typical incorporative languages the Iroquoian and Eskimo may serve. All the incorporative forms of speech in America do not, however, proceed upon identical lines; and some that do incorporate, like Kootenay and Eskimo, often have one or more cases. According to Dixon and Kroeber many Californian languages do not possess the feature of incorporation at all (such are, for example, Maidu, Pomo, Yuki, etc.). As types of incorporating languages less complete than Iroquoian we have Kootenay, Siouan, Aztecan. Some of the Central and South American tongues seem also to have little incorporation. Otomi and Maya appear to be evolving in somewhat the same direction as modern English, away from incorporation and grammatical plethora. Many of the Amerindian tongues are both prefix and suffix languages; others prefer prefixes, others, again, suffixes. Some possess, and some do not, a plural form for nouns; a dual; gender-distinction in pronouns; a high development of demonstratives; reduplication; syntactical cases, etc. A few possess grammatical gender and some exhibit differences in the words used by men and women. In the matter of phonetics the languages of the American aborigines are remarkably divergent, some being extremely harsh, guttural and consonantic, others equally smooth, soft and vocalic. The absence of certain consonant sounds and the equivalence of certain vowels and consonants characterize some forms of American speech. Euphonic changes are of major or minor importance. Sentence-construction differs greatly in various tongues. The position of the adjective is not always the same. The Haida language has even a distinction like that between our *shall* and *will.* Careful investigation of the many Indian languages, as yet studied imperfectly, if at all, may reveal other interesting linguistic phenomena. How much has been written about and in some of the languages of primitive America may be seen from the bibliographies of Pilling! Our knowledge of them varies from a brief vocabulary of the Esselenian to the exhaustive dictionary of Yahgan compiled by Bridges. The native literature runs from the unrecorded tales of the northernmost Athapascans to the poetry of the ancient Mexicans and Peruvians, some of which has been handed down from pre-Columbian times. The only actually phonetic (syllabic) alphabet now in use among the Indians (except the syllabaries introduced by missionaries among the Athapascans, Crees, etc.) is post-Columbian — the invention of a half-blood Cherokee. A sort of alphabet has, however, sprung up more recently among the Winnebagos. The development of picture-writing varied very much among the numerous tribes, as may be seen from Mallery's classic study of the subject. Sometimes, as is the case with the Kootenays, ability to draw does not seem to have been accompanied by exuberant pictography. The Walum Olum of the Delawares, the "calendars" of the Kiowa, Sioux, Pima, etc., are special developments of primitive records, the highest form of which is seen in the manuscripts ("books") of the Aztecs and Mayas of a religio-historical character. The pictographic records of the Ojibwa "medicine men" have been studied by Hoffman, and the rite-literature of the Cherokee by James Mooney. The native literature of primitive America has been the subject of special monographs by Dr. D. G. Brinton. The Spanish-American countries have furnished several writers and investigators of Indian descent.

There might be mentioned here also the "Chinook Jargon" of the Columbia River region, the "Ligoa Geral" of Brazil, and the minor jargons and trade languages of other sections of the continent, which prove how the Indian has compelled the white man, more or less, to use his language in some form or other for the purposes of friendly or commercial intercourse.

Religion.— The mythology and religion of the American Indians have received particular treatment at the hands of Müller, Brinton, Powell, etc. Perhaps the most general myth of importance is that of the divine hero, teacher and civilizer, who, after accomplishing his labors, leaves the earth, promising to return

at some future time. This myth is found in Mexico (Quetzalcoatl), Yucatan (Kukulkan), Colombia (Bochica), northeast North America (Manabozho, Gluskap, etc.). Somewhat analogous is the myth of the twin reformers of the primitive world among the Pueblo Indians, Navahos, etc. The Iroquoian stock have the myth of the contest of the good and bad mind. The Algonkians have a myth-circle of the rabbit, the tribes of the northwest Pacific coast one of the raven and thunder-bird, the Rocky Mountain peoples one of the coyote, the Brazilian Indians one of the jaguar, etc. Some of the tribes are very rich in animal myths and, as Mr. Mooney asserts, the characteristic tales of "an 'Uncle Remus' nature" found among the Cherokee and other peoples have not, as many suppose, been borrowed from the negroes of the South. Even the famous "tar-baby" tales have their independent Amerindian analogues. Flood-legends are widespread in America and vary from the simple, locally colored stories of rude Athapascans to the elaborate conceptions of the civilized peoples of Mexico, Central America, etc. The cardinal points and the number four have developed with many tribes a rich symbolism, with which the chief colors are often connected.

The "medicine men" of the Ojibwa, the Cherokee, the Apache, have been investigated by Hoffman, Mooney and Bourke, and a large amount of accurate and authentic information concerning shamanism among the Amerindian peoples has been accumulated. The power of the "medicine man" varies much from tribe to tribe,— with some he is a personage of little or no importance; with others he is the controlling influence in secular as well as in religious affairs. The acme of such influence is found among some of the tribes of Guiana and Brazil. These "medicine men" had often their secret societies and "lodges" into which chosen neophytes were admitted with appropriate ceremonies. They had also, with many tribes, the control of the rites to which the youth were subjected at the time of puberty, with others they performed such marriage ceremony as existed. Besides these shamans, there were "prophets" and religious reformers, especially since contact with the whites. The widespread "Ghost Dance," in its more recent outbreaks, has been studied in detail by Mooney. Worthy of note is also the "new religion" of the Iroquois, and the "Shaker" religion of the Indians of Puget Sound. The investigations among the Pawnee by Miss Fletcher and G. A. Dorsey have demonstrated the existence of a relatively high form of primitive religion in a rather unexpected quarter,— their worship of the morning star in connection with agriculture was, however, at one time accompanied by human sacrifice. The mortuary rites of the American Indians, corresponding to diverse ideas of the soul and its future in the other world, varied from simple neglect of the corpse to what is represented in material form by some of the mounds of the Mississippi Valley and the stone tombs of Peru. The mortuary customs of the aborigines of North America have been made the subject of a special monograph by Dr. Yarrow, and the doctrine of "animism" among the South American peoples has been treated at length by Koch. The contemplation of the *totem* (properly Ojibwa *ododema*),— tribal or family mark,— of certain Algonkian tribes has given rise to theories of "totemism," concerning which there is much dispute in the world of science. "Fetishism," as exemplified in the Zuñis, has been investigated with some detail by Cushing. Cannibalism (the word *cannibal* is the corrupted form of a South American tribal name) has been rarer in America than is generally believed. Outside of its occurrence through necessity in ways known to civilized peoples, it was chiefly partial and ceremonial. Epicurean cannibalism flourished along the coast of South America and on some of the Caribbean islands; ritual cannibalism among certain tribes of the northwest Pacific coast, in ancient Mexico, etc. The almost extinct Tonkaways of Texas have the reputation of being the "last of the cannibals," while the Attacapas owe their name to this practice attributed to them by their neighbors. In the legends of the Cree and Ojibwa tribes of the Algonkian stock, a cannibal giant (wendigo) figures, and a horror of human flesh eating is expressed at the present time, whatever may have been the case in the past. From the condition of human bones and other remains in the shell-heaps of various parts of the coast, some authorities have come to the conclusion that cannibalism did exist in prehistoric ages among some of the Indian tribes. Religious ideas approximating to monotheism are attributed by some chroniclers and investigators to some of the more enlightened aboriginal rulers of Mexico and Peru. In these regions of the continent, as also in Central America, architecture and the arts of commemoration and record were at the service of religion. See AMERICAN MYTHOLOGY; FOLK-TALES AND MYTHS OF AMERICAN INDIANS.

Amusements.— The games of the American aborigines, some of which, like lacrosse, have passed over to their conquerors, are of sociological and religious significance in many instances. Stewart Culin has made a special study of the games of the North American Indians, and rejects the theory favored by Tylor and others, that many of them (for example, Mexican *patolli*), are imports from Asia. The games of the civilized Aztecs seem to be but "higher developments of those of the wilder tribes," and those of the Eskimo are modifications of games found among other aboriginal peoples of America. Among characteristic Amerindian games may be mentioned the gambling game with sticks, the hoop-and-pole game, the ball-race of the southwestern United States, the ball-games of eastern North America, the woman's game of double ball, foot-races, the snow-snake, etc. Culin holds that back of every game lurks "a ceremony in which the game was once a significant part." The variations in games do not follow linguistic lines. One centre whence games have radiated and where some of their oldest forms are still to be found is in the southwestern United States, from which their migrations can be traced north, northeast, east and south. Interesting modifications arise from conditions of environment.

Arts and Inventions.— The arts and inventions of the American Indians correspond to the extent and variety of their environment. The mass of the inhabitants of the continent at the time of its discovery were hunters and fishers, or agriculturalists of the Stone Age, most of whom had some knowledge of pottery-making. The house followed the lines of climate and culture, from the snow *iglu* of the Eskimo and the rude *wickiup* of the Utes to communal houses of the Mohegans, the Iroquoian "long-house," phalansteries of the Pueblan and Central American areas, and the stone dwellings of a more or less pretentious sort of the civilized peoples of Mexico, Central America and Peru. The cavate lodges and cliff-dwellings of Arizona and New Mexico, the wooden (sometimes underground) houses of the northwest Pacific coast, the skin-tents of the plains tribes and the wigwams of the Algonkians, the earth-lodges of the Mandans, etc., correspond to environmental stimuli. A like variation may be seen in the cradles of the American aborigines, studied by Mason, and in their means of transport on the water,— kayaks, "bull-boats," woodskins and balsas, dug-outs, canoes of pine and birch bark, large and small, and of all varieties of design and finish. In North America the Algonkians and Iroquois, and in South America the Indians of the great Brazilian water-ways, have made themselves celebrated for their skill in navigation. So too has the Eskimo with his kayak and the Peruvian with his balsa. The Algonkian Etchemins are literally "the canoe-men." The seagoing canoes of the fishing tribes of the coast of Alaska and British Columbia also deserve mention. On land some of the American Indian tribes have used the dog (Eskimo in particular) and the sled (the Algonkian toboggan, adopted by the whites for amusement purposes, is a special form), while in Peru the llama has been employed for ages for "packing," but not for draft purposes. The use of the horse and the modifications of primitive culture thereby induced in the Indians of the plains of the Missouri-Mississippi Valley, the llanos of Venezuela, the pampas of the Argentine, etc., are, of course, post-Columbian. So, too, the influence of sheep culture upon the Navaho and their primitive industries, and of the cow among certain South American tribes. The only animals domesticated by the Indians whose use amounted to a considerable factor in their social and religious life were the dog and the llama, the latter in Peru and Bolivia only. The other half-domesticated animals and birds are of little importance as culture elements. The domesticated dogs of pre-Columbian America represent several diverse species of *Canidæ*. The absence of such domesticated animals as the cow, the horse, the sheep, etc., in pre-Columbian America accounts for certain limitations of its culture as compared with that of the Old World. Pets, however, bird and beast, were very common, especially in Brazil and Guiana. The disappearance of the wild buffalo and other animals of the chase, since the coming of the whites, has been fateful for some tribes,— the contact with the latter as represented by the various "fur companies," etc., has caused many changes in the life of the aborigines, seldom for the better.

As Mason has pointed out, the Amerindian traps and other devices for the capture of wild animals indicate intellectual skill and marvelous adaptation to the habits and actions of these creatures. The Eskimo harpoon and its appurtenances, the simple and composite bow, the arrow-poisons of some North American and many South American peoples, the manufactures of obsidian and jade in ancient Mexico, cotton weaving and dyeing in the more southern regions, maguey-paper making in Mexico and Central America, stone carving (from Mexico to the Argentine), feather-work (in the southern United States, Mexico, Central America and parts of South America), gold working (in the Isthmian region, Colombia, etc.), the hammocks of the Venezuelan tribes, the fish-poisoning devices of many peoples of South America in particular, the fine pottery of many regions of the continent, the *quipus* or knotted record-strings of the ancient Peruvians, the primitive drum-telephone of certain Brazilian Indians, the blow-gun (southeast United States and South America), cassava preparation (northern South America), the bolas of the Pampean tribes, etc., represent the diversity of invention and manufacturing skill among the American aborigines. The lamp of the Eskimo and some of the Indian tribes of northwestern North America is *sui generis* (its importance has been emphasized by Hough). Methods of computing time, season, etc., vary from the slanting stick of the Algonkian Naskopi to the elaborate calendar systems of Mexico and Central America. Of musical instruments, the drum, the flute, the pan-pipe, and the "musical bow" were known to the American Indians. Songs and dances to the accompaniment of these were in vogue. Practically all stages of primitive culture were to be found in pre-Columbian America, if we may judge from the tribes now surviving, from the savage Seris to the ancient Mexicans, Mayas and Peruvians. Moreover, within the bounds of the same linguistic stock, as noted above, there may be found tribes representing a high and a low stage of development; as for example, the Aztecs and the Utes of the Shoshonean stock, the Dogribs and the Navahos of the Athapascan, etc. Some tribes were pre-eminently fishers, others hunters. Many excelled in both, like the Eskimo and some of the peoples of the northwest Pacific Coast. Some sort of agriculture was widespread in America — the cultivation of corn, beans, varieties of pumpkin and squash, etc., was known all over eastern North America, and the regions of the southwest, etc.; and typical tropical and semi-tropical and other plants and fruits (potato, tomato, maize, pineapple, tobacco, varieties of cotton, manioc, sweet-potato, cacao, coca, etc.) were cultivated in the more southern regions of Mexico, Central and South America. The spread of tobacco and maize in North America and of certain other plants in Central and South America indicates agricultural receptiveness on the part of the many tribes concerned. The capacity of the American Indians generally for agriculture has been underrated probably, as both the desert-born cultivation of the Pueblo Indians and the tropically stimulated cultivation of the Indians of South America indicate. The arid regions of the Peruvian coast offer another example of considerably developed agriculture. In America utilization of the gifts of the earth varied from the seed picking and root digging of the Utes to the market gardens and chinampas of ancient Mexico. How the necessities of agriculture can shape a religious system may be seen from the rites and ceremonies of the Pueblo Indians, the cult of "mother corn," etc. With

some tribes tobacco was more or less of a sacred plant, also the mescal.

Position of Woman.— The relation of women to agriculture gave them a higher standing with certain tribes than would otherwise have been the case. With the Iroquois the position of women was very high and to them was allotted a considerable share in the government, peace negotiations, etc., and female chiefs were by no means unknown — women were the "mothers of the nation." Among the Mayan peoples of Central America woman's position was also high. Many of the priests were women, and they were also commonly the leaders of their tribes in rebellion against the Spaniards — the most famous was Maria Candelaria, "the American Joan of Arc," who led the insurgent Tzendals in the 18th century. In ancient Mexico and Peru the position of woman was perhaps not quite so high. Among some tribes the position of woman was very low, and her sexual peculiarities added to the disesteem in which she was held, as for example, among the Tacanan Araunas of Bolivia. The Athapascan tribes vary much in their treatment of woman — with some she is little better than a slave or servant, while with at least one Alaskan people of this stock female chiefs existed at times. The "purification" of women at the period of their menses, and the segregation of girls at the time of puberty, were accompanied with many rites and ceremonies among various tribes from the rude Athapascans to the civilized Aztecs. The curious custom of the *couvade* (imitative child-bed on the part of the husband) prevailed among many Venezuelan, Guianian and Brazilian peoples. The relations between environment and the share of the sexes in culture has been investigated by Mason; according to whom the zenith of virile Amerindian art is reached in Peru, while in Colombia we find woman as farmer, weaver and potter. In the Oregon-California region one art, basket-making, reaches its acme of development in the hands of woman. A large female influence in religion is noticeable among the Pueblo Indians. Among some tribes, for example, the Hurons, the weregild for killing a woman was greater than that for a man. Some sort of matriarchal system, with maternal descent, prevailed very commonly in pre-Columbian America; among certain of the Koloschan Indians, for example, a man was considered to be in no sense related to his father, his sole parent being the mother. Besides this extreme form, numerous other varieties occur among the tribes now existing, the system in vogue among the Iroquois, etc., being more complicated and adapted to social needs. The systems of marriage known to the American Indian varied from the absence of any particular rite or ceremony to selection of the wife by the old women of the tribe, as among the Hurons, or the uniting of the couple by the "medicine men." Some of the tribes of the Brazilian forests, ranking very low in culture, are strictly monogamous; while peoples of higher civilization, like the Chibchans, Mexicans, Peruvians, etc., were polygamous or concubinative, or both. Marriage by purchase was found over a large area of America; but here as in other parts of the globe, the "money" received was often rather a compensation to the parents for the loss of their daughter than a real sale of her to a suitor. Divorce, in many forms, is known to the primitive Americans, both by mere word of the husband and according to set forms and rites. Consanguineous marriages were strictly avoided by many tribes; but among a few, such as some of the lowest Athapascans, incest was not condemned. In the matter of the sex-relations, as in many other fields, the American Indians exhibit almost all possible phases from the monogamic chastity of some of the lowest peoples to the unnatural indulgences of the Peruvians. Runaway matches and marriages for love, in spite of the contrary opinion entertained by some authorities, have been by no means uncommon throughout the continent. Suicide on account of unsuccessful wooing by both sexes is also not at all rare. Some peoples, too, have developed love-songs of a romantic order, for example, the *yaraveys* of the Quechuas.

Government.— The systems of government of the American Indians and their tribal organizations range from the simple democracy of the Kootenays and some of the Brazilian Indians to the elaborate state institutions of the ancient Mexicans and Peruvians, which in several respects resembled the corresponding institutions of Mediæval Europe or the ancient classic world. The power of the chief, however, seems everywhere to have had limitations, and some tribes distinguished the permanent peace chief and the temporary war chief. Chiefs were generally elected, either from the body of the tribe or from certain specified families. "Totemism" and secret societies are not found to any extent, if at all, among certain tribes (the Kootenay, for example); while with many of the peoples of the northwest Pacific Coast they are perhaps the chief feature of aboriginal society, as Boas has recently shown. Property rights are represented in many stages, from the semi-anarchic Eskimo to the Aztecs of Old Mexico and other peoples of Central and South America. Slavery existed among many tribes, and on the northwest Pacific Coast a sort of traffic in human chattels had arisen. See SLAVERY.

Trade and Commerce.— Within the spheres of the culture-centres of Mexico, Central America, Peru, etc., trade and commerce were well developed. The Columbia River region was the scene of a less developed trade; while the southeastern United States, the region of the Great Lakes and country west and south of them, had also their important distributing points. The region of Bering Strait was likewise an Asiatic-American commercial centre.

Education.— With the lower tribes generally, such education as was imparted to the children was given by the father to the boys and by the mother to the girls. People like the Iroquois, the Siouan Omahas, etc., used the instruction of tales, legends and proverbs. The ancient Aztecs and some of the other semi-civilized peoples of Mexico and Central America had schools for boys and others for girls, in which the duties proper to each sex were taught under the supervision of the priests.

Physical Characteristics.— The physical characteristics of the aborigines of America mingle uniformity with diversity. The skin color, popularly styled "red" or "copper," is

Government.— The systems of government of the American Indians and their tribal organizations range from the simple democracy of the Kootenays and some of the Brazilian Indians to the elaborate state institutions of the ancient Mexicans and Peruvians, which in several respects resembled the corresponding institutions of Mediæval Europe or the ancient classic world. The power of the chief, however, seems everywhere to have had limitations, and some tribes distinguished the permanent peace chief and the temporary war chief. Chiefs were generally elected, either from the body of the tribe or from certain specified families. "Totemism" and secret societies are not found to any extent, if at all, among certain tribes (the Kootenay, for example); while with many of the peoples of the northwest Pacific Coast they are perhaps the chief feature of aboriginal society, as Boas has recently shown. Property rights are represented in many stages, from the semi-anarchic Eskimo to the Aztecs of Old Mexico and other peoples of Central and South America. Slavery existed among many tribes, and on the northwest Pacific Coast a sort of traffic in human chattels had arisen. See SLAVERY.

Trade and Commerce.— Within the spheres of the culture-centres of Mexico, Central America, Peru, etc., trade and commerce were well developed. The Columbia River region was the scene of a less developed trade; while the southeastern United States, the region of the Great Lakes and country west and south of them, had also their important distributing points. The region of Bering Strait was likewise an Asiatic-American commercial centre.

Education.— With the lower tribes generally, such education as was imparted to the children was given by the father to the boys and by the mother to the girls. People like the Iroquois, the Siouan Omahas, etc., used the instruction of tales, legends and proverbs. The ancient Aztecs and some of the other semi-civilized peoples of Mexico and Central America had schools for boys and others for girls, in which the duties proper to each sex were taught under the supervision of the priests.

Physical Characteristics.— The physical characteristics of the aborigines of America mingle uniformity with diversity. The skin color, popularly styled "red" or "copper," is

PICTURE WRITING OF THE OJIBWAY INDIANS

designated by Mantegazza, "burnt coffee," and by Brinton, "brown of various shades, with an undertone of red." This but varies from rather dark to rather light. Among the lighter tribes have been reckoned the Koloschan Tlinkit, the Bolivian Yurucari, etc., and among the darker the Charmas of the Gran Chaco, the Bolivian Canisianas and a few other tribes of South and Central America. The hair is generally termed "black," but, as Brinton notes, there is in it "a faint under-color of red," which shows up more in childhood and seems much more prominent with certain tribes than with others. Red hair is known among American Indians, but in some cases (certain South American tribes, for example), its occurrence may be due to infusion of white blood. The eyes of the Indians are, with rare exceptions, dark brown. The stature varies from rather low to rather high, represented on the one hand by some of the shorter Brazilian tribes and on the other by the Patagonian "giants." Among the peoples presenting many individuals of tall stature may be mentioned the Yumas and Pimas, some of the Muskhogean tribes, some of the Crees, Ojibwa and eastern Algonkians, Pawnees, Iroquois, Siouans, Huaveans, Ramas, some of the Cariban tribes, Yurucari, Cayubabas, Guaycuruans, Patagonians, etc. So far as is known no dwarfish people comparable to the dwarf races of the Old World existed in America, although the skeletons from certain Peruvian tombs prove the existence of a dwarfish element in the general population; and the stature of many individuals among certain Brazilian tribes is so low as to induce some authorities, with Kollmann, to predicate the former existence of a dwarf race. In the relations of trunk and limbs and in the relation of one limb to another many variations occur among the Indians, due to occupation (canoeing, etc.— and, since the advent of the whites, horse-riding). In primitive America all the chief forms of skull (often with artificial flattening, etc.) are found. Among the dolichocephalic (long-headed) peoples are the Eskimo and Iroquois generally, some of the Muskhogean tribes, Otomis, Aymaras (partly), Tapuyas and Tupis (largely), etc. Of the brachycephalic (broad-headed) may be mentioned the Araucanians, Caribs, Arawaks, Patagonians, Mayas, many of the tribes of the Pacific Coast region of North America, etc. The civilized peoples of Mexico, Central America and Peru appear to have been of stature below the average and of varied skull form tending to brachycephalic, indicating mixtures of types. In the Columbia River region type-mingling is indicated also by both stature and skull-form. The Peruvian region is another centre of race-mixture, as evidenced by skull-form. The oldest skulls discovered in prehistoric burial-places or in geological *situ* are not distinct from the American types — the latest found, the "Lansing skull," is quite Indian. The skull capacity of the Indian is below that of the white in general, but many exceptions occur. The brains of the less cultured Indian peoples (Fuegians, Eskimo), show no decided anatomical inferiority to those of civilized Europeans. Great varieties of build and set of body are found among the American Indians, from the half-starved Fuegians to the well-fed and corpulent Iroquois. Small feet and hands are very common. Among many tribes in various parts of the continent handsome men and women of considerable beauty are to be found. In the case of women, an admixture of white blood often enhances their beauty.

Race-Fusion.— The intermingling of the American Indians with the intruding white race has been much greater than is generally believed. The extent of this fusion of races varies from certain parts of North America with their classic Pocahontas examples to Uruguay, in South America, where 90 per cent of the population are said to be of mixed blood. The Eskimo of Greenland have intermarried with the whites (Danish fathers, native mothers), so that except in the parts remote from settlements no pure-blood Eskimo exists; and the same is true of a good deal of Labrador, where the contact has been with fishermen of English descent. The Micmac, Abnaki and related Algonkian tribes of Maine, New Brunswick, etc., have a large admixture of white blood (French fathers, native mothers), and all over Canada and the northwestern United States in the early days of colonization and exploration the French traders, trappers, *voyageurs* and *coureurs des bois* mingled freely with the native women, particularly those of the various Algonkian peoples of the Great Lakes and the West. The Hudson's Bay Company, by introducing employees of English and Scotch descent into the Canadian Northwest, made possible other *métis,* of which those of Scotch descent on the father's side are said to be healthy and sturdy specimens of humanity with more than ordinary capacities. As indicated by the present condition of the Iroquois on the reservations in Quebec, Ontario and New York, some infusion of white blood has taken place from very early times. Here the combination of white mother (often an adopted captive) and native father is more common than is usual in race-mixture. The Cherokee had an admixture of white blood in ante-Revolutionary days, to which Mooney attributes much of their culture-achievements since that time. In Mexico, Central America and South America generally, as Talcott Williams has very recently noted, the half-breed element is very large indeed, for the native population was never exterminated by the whites as some histories still teach. Of the 40,000,000 inhabitants of South America it has been estimated that less than 10,000,000 can lay any claim to pure white blood. There is reason to believe that the future of some of the South American countries will be as much in the hands of the Indians as in those of the whites. In Mexico, parts of Central America, Colombia, Peru and Chile, the strain of Indian blood represents able and intellectual aboriginal peoples. In certain parts of South America, and, sporadically in northeastern North America, intermingling of Indians and negroes has occurred, giving rise to the so-called Cafusos, etc., of Brazil, and a few other small groups. The mixture of white-Indian-negro is also found here and there. In some of the Spanish-American countries there is a special vocabulary to designate the numerous degrees of *métissage.* In the Canadian Northwest the half-breeds have taken a prominent part in the development of the country (one noted *métis,*

Norquay, was premier of the province of Manitoba), and they are likewise noteworthy in the annals of the northwestern United States. In Mexico and Central America, not alone the *mêtis* but the Indians themselves have produced celebrated men. Juarez, the liberator of Mexico, a really great man, was a full-blood Zapotec and President Barrios of Guatemala a Cakchiquel (Mayan stock).

Treatment by Whites.— The ill treatment of the American Indian by the whites has often been such as to stamp with eternal dishonor the conquering race. Massacres, broken treaties, land-robbing, commercial swindles, etc., mark the path of advancing "civilization." English, Dutch, French, Portuguese and Spanish have all been guilty at some time or other. The English in Newfoundland, the Americans in the West, the Castilians in northern Mexico and Yucatan, have exterminated or sought to exterminate whole tribes. We must, however, believe that the accounts of the early chroniclers concerning the "millions" of Indians slaughtered by the Spaniards were the customary exaggerations of those who sing the victor's deeds. Peru and Mexico, for example, would not contain so many Indians to-day were those stories literally true. Against the centuries of dishonor in the treatment of the Indians by the whites we may place the efforts of missionaries of all faiths, from the good Las Casas in New Spain to Duncan of Metlakahtla. The Jesuits among the Iroquois and Algonkians in North America, the Moravians among the Eskimo and some of the Algonkians and Iroquois, have all done good work, which only the incapacity or worse of governmental authorities has made null. The missions in California and the "reductions" in various parts of South America (Paraguay in particular) might have succeeded in keeping the Indians gentle and loyal sons of the Church had the good fathers been forever in charge, but the oncome of the more strenuous life of the whites doomed them to helplessness. The story of the Paraguayan experiment is one of the most interesting in the annals of mankind, but also one of the most disheartening. Against such failures a few bright spots may be set,— the Fuegian mission for example. A better treatment of the Indians still within the borders of the United States has been in progress for several years. See INDIAN AFFAIRS.

Influence on Civilization.— The contributions of the aborigines of America to the world's stock of civilizing factors and influences are much more numerous and of greater importance than is generally thought. Besides the innumerable place-names in all parts of America of Indian origin, the Algonkian, Peruvian, Brazilian, West Indian, Guianian, Venezuelan and Mexican words in English, French, Spanish and Portuguese (whence many of them have spread into all the civilized languages of the world) are able remembrancers of the conquered race. The literature of the Spanish-American countries and of Brazil has been more or less affected by the stimuli of native theme and treatment. Many of the old dances and folk-customs still survive even where Christianity has been at least outwardly accepted and have sometimes been adopted by the descendants of the European colonists. The 'Hiawatha' of Longfellow and the tales and dramas based upon the deeds, adventures and romantic episodes in the lives of King Philip, Pocahontas, Pontiac, Tecumseh, etc., to say nothing of the novels of Cooper and his successors, indicate that the Aryan mind of the Anglo-Saxon order has found treasure in the Amerindian soil. In Mexico and other parts of Spanish America the cathedrals and other religious edifices, by intention or by happy chance often occupy sites sacred to pagan deities ages before Columbus' discovery — so the new religion gathers strength from the old, and the dislocation of faith so common in Protestant countries is avoided to a very large extent. Of more material things, we owe largely to the Indian the paths over which our highways and our railroads run, while many of our cities and towns have only sprung up on the old camp-sites of our predecessors. The great importance of some of these "Indian ways" in the history of the United States has been pointed out by Hulbert. The Indians' knowledge of the great water-ways of the country, of portages and trails through forest and over mountain, has made possible colonization and settlement otherwise utterly out of the question. Indian hunters and fishers, scouts, guides, canoe-men, carriers and packers, in all sections of the American continent, have been indispensable to the progress of white civilization. Nor have Indian slaves and servants been few or without social significance in some quarters; while French, Spanish and English have at times availed themselves of the services of Indian warriors,— the Iroquois enlisted for the North and some of the Cherokee for the South in the Civil War, and then the government has sometimes set one tribe off against another. In Canada and part of the northwest of the United States, where commingling of the races has taken place, the civilization of the land owes even more to the half-breed, *voyageur, coureur des bois,* etc, than to the Indian himself. See CANADA — POPULATION; RACIAL DISTRIBUTION AND IMMIGRATION.

Throughout the continent — more especially, however, in parts of South America — devices for hunting and fishing and appliances in woodcraft, primitive agriculture, etc., were transferred to the European colonists during the period of settlement, and many of them are still in active use. Fish-poisoning by narcotics, the use of the blow-gun for killing birds and small animals without damaging the skin, methods of stalking beasts of the chase, certain traps and snares, etc., belong here. In connection with agriculture we have menhaden-manure, guano, etc., the planting of corn and beans or pumpkins together, the burning over of land before tillage, etc. But it is upon the food-supply of the world that the American Indian has exerted the greatest influence. Potatoes (common and sweet, both), maize and the tomato, now in use by all the civilized world, were first cultivated by him and taken over by the whites after the discovery. Cacao, vanilla, jalap, the kidney bean, several varieties of squash and pumpkin, manioc, Jerusalem artichoke, coca, agave, quinoa, persimmon, and perhaps also the peanut, came to us from the Indians. Maple-sugar and maple-syrup, pemmican, jerked beef, etc., are from a like source. Tobacco, the great narcotic, was one of the first gifts of America to the Old World. Of drinks the American Indian has given us Paraguayan *maté,* "Labrador tea" and several other like concoctions, chocolate, Mexican *pulque* and a considerable number of other intoxicating beverages from South America.

Many medicines and medicinal plants were made known to the whites by the Indians, and in the era of settlement and colonization the "Indian doctor" (male and female) was not unimportant — New England, for example, had its "Joe Pye," after whom the "Joe Pye weed" (*Eupatorium purpureum*) is named. The Californian Indians have furnished perhaps the three most important contributions of recent years to the American pharmacopœia. South America, besides numerous locally known remedies, etc., has furnished the world-famous *quinine,* and *ipecacuanha,* while the drugs *cocaine* and *curari* must ultimately be credited to the aborigines of America. Many dye-stuffs and dye-woods were first given to the civilized world by the Indians, both for domestic use and for employment in the larger world of æsthetic manufacture. These dyes range from the poke of northeast North America for dyeing basketry to the famous roucou or anotto of Venezuela, used, among other purposes, for staining cheese. Pottery and other household utensils of Indian manufacture are used throughout Spanish America. The hammock of the Arawak Indians belongs now to all civilized peoples. All that india rubber means, civilization owes to the Indian. Both in small things and in great the American aborigines, through their gifts to the white race, will long be remembered, even if, as some authorities (upon imperfect evidence) believe, they are rapidly passing away. On this point one may cite the remark of Deniker that Humboldt in 1825 estimated the total population of America at 13,000,000 whites, 6,000,000 half-breeds, 6,000,000 negroes and 9,000,000 Indians, while a comparative computation made in 1916 reckoned 120,000,000 whites, 42,100,000 half-breeds, 12,006,000 negroes and 12,000,000 Indians; total, 186,106,000. See AMERICA: POLITICAL DIVISIONS.

Antiquity of Man in America.— The question of the antiquity of the American Indian culture is difficult to settle satisfactorily. Time must be allowed for the divergence of the original stock into numerous (more numerous in pre-Columbian eras) tribes and peoples inhabiting America at the time of its discovery,— time for the production of the Eskimo and the Iroquois, the Carib and the Patagonian. Time, again, must be allowed for the development of the Aztec from the primitive Shoshonean, the Mayan from the rude stock of that people, the Chibchan from the savage Bolivian, the Peruvian from the ancient barbarian of equatorial America. Then the civilizations of Mexico, Central America and South America as such probably took ages to rise and flourish. Town and village life, with all its social and religious implications, the differing architectural monuments of the various centres of American civilization, etc., did not spring up in a day, any more than did the culture of mediæval Europe. The domestication of the dog, the llama, etc., the change of maize, tobacco, the squash, the tomato, the potato, the pineapple, etc., from wild to cultivated plants, require a long lapse of time. Moreover, it is now known that American Indian languages do not now change and have not in the past changed at the fast rate once assigned to them by philologists. So, while one may not believe that America was the original habitat of the human race, he may be certain that very many millenniums have elapsed since the "Red Man" began his career as the autochthone of the New World. There seems every reason to believe that at the close of the Glacial Age man had spread over a considerable portion of both North and South America and was contemporary with European man of an early epoch. To calculate man's residence in the American environment by years is impossible on present evidence. Dr. Stoll assures us that the linguistic phenomena met with in the Mayan dialects alone require thousands of years for their evolution, and some of the results deduced from the Mayan hieroglyphs by certain investigators imply the existence of civilization of the Central American order for very many millenniums. Perhaps it is fair to say that man has been in America at least 25,000 years and not more than 200,000, and that the civilizations of Mexico, Central America and South America were probably as long-lived as those of Rome, Greece, etc. They were also in many respects just as typical of human attempt and achievement, for the American Indian was a man as we are men.

Editorial Staff of The Americana.

INDIANS, Canadian. There is no figure in history so picturesque as that of the North American Indian. The stormy life of the various nations or tribes, the concentrated cruelty of individual character combined with loyalty and honor in tribal relations; the almost constant and bloody struggles between the tribal units, and the prolonged conflict with the white invaders of the continent; the complexity of the savage temperament in its mingled simplicity and guile, its courage and endurance, its treachery toward foes and cruelty in war, its pride and prudence alternating with periods of insane recklessness and a humility akin to that of a beggar, its self-restraint and moments of unbridled rage, its strange conjunction of greatness and littleness; stamp the American aborigine as a most extraordinary human product. See INDIANS.

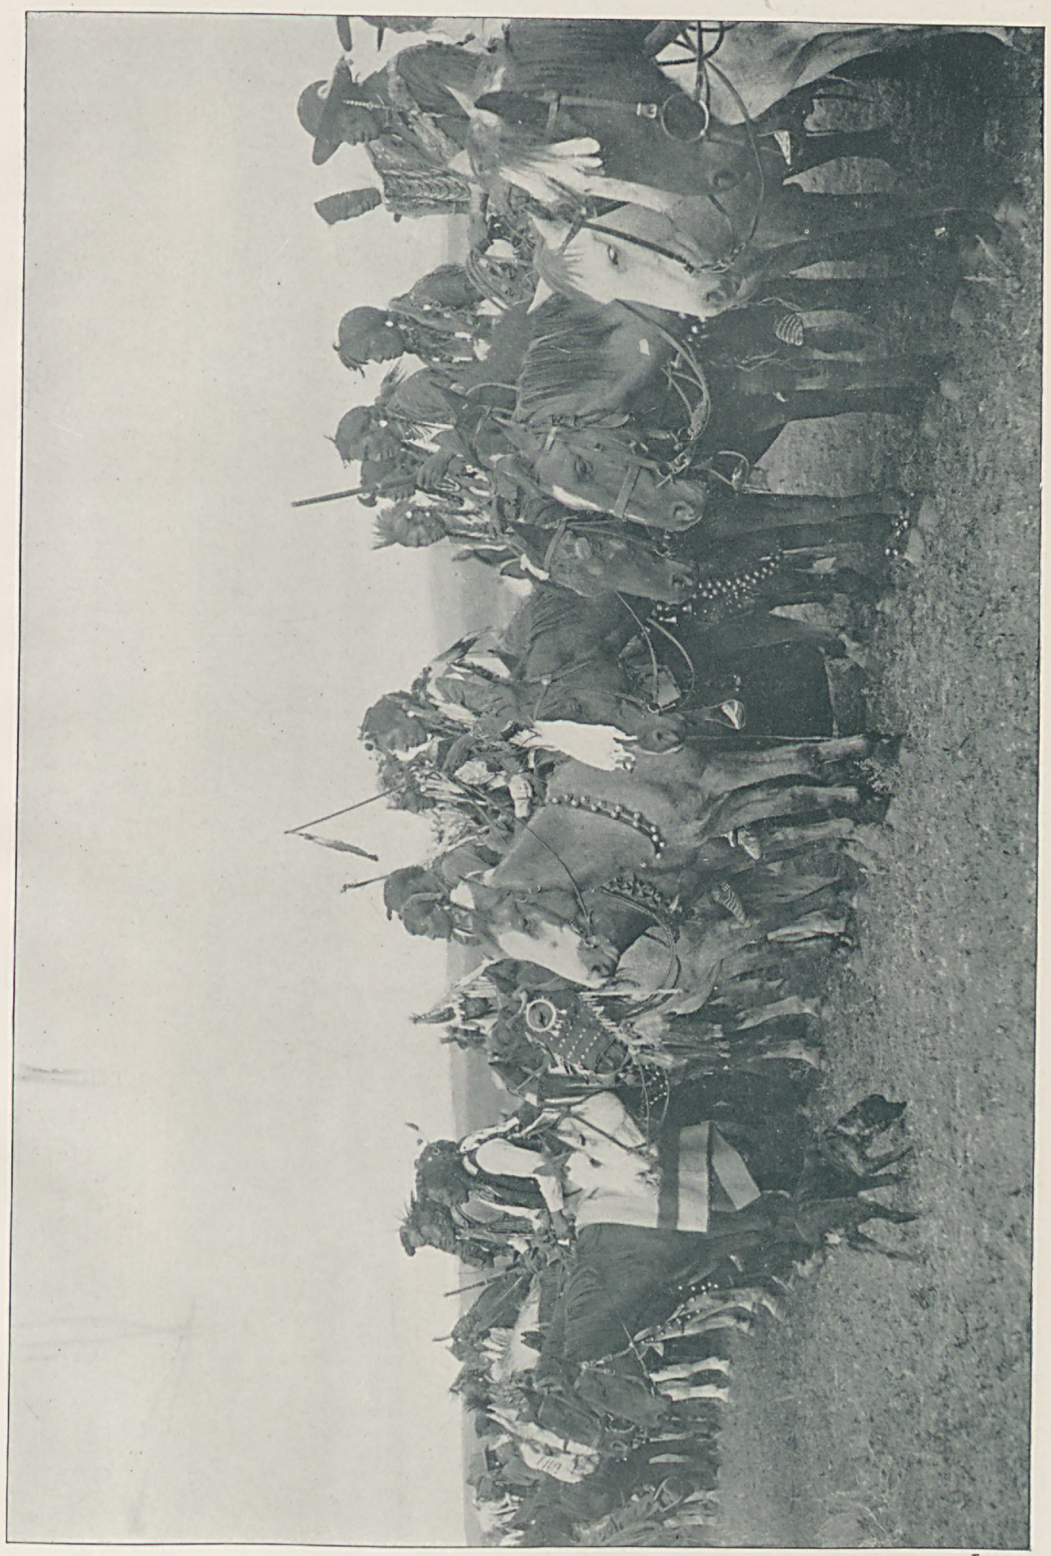
Character of the Indian.— History has yet to do him justice. Cold and hard, passionate and revengeful, ignorant and superstitious, keen and quick in thought, he has yet in pre-civilization days never been guilty of the effeminate and meaner vices which destroyed peoples such as the Romans or the Aztecs. Love of liberty in its wilder forms, and contempt for all arbitrary rule or personal control, he carried to an extreme greater than can be elsewhere paralleled. Sleepless suspicion of others was a part of his environment of war and treachery. As with nearly all savage races, his strategy was that of surprise, followed by ruthless and unhesitating slaughter. A product of primæval conditions, he could not change his character without deterioration, or his mode of life without physical and mental injury. Civilization indeed has destroyed the Indian. In curbing his wilder passions it has usually developed the meaner ones, and the destruction of the environment which made him the barbarous yet noble owner of a boundless domain has cramped his intellectual acuteness, starved his wonderful physical qualities, and fatally affected the code of morality which he undoubtedly possessed. Agricultural pursuits and a veneer of Christianity may fit the survivors for life amidst new conditions, but the result of this development, in Canada at least, no more typifies the Indian of past centuries than the Greek of to-day is the true heir of Leonidas at Thermopylæ, or the modern native of Rome the just inheritor of imperial valor.

Distribution of the Indian Tribes.— When the first discoverers and explorers found their way amidst the wilds of Canada, they came into collision with various Indian nations. The great family of the Algonquins extended right up through the centre of the continent. They formed the chief central race of early Canada, and reached in scattered masses from the Atlantic to Lake Winnipeg and from the Carolinas to Hudson Bay. Cartier met them when he ascended the Saint Lawrence; the early English settlers encountered them along the coasts of Virginia; the people of New England fought them under King Philip. William Penn made peace with them under the trees of the Keystone State, and the French Jesuits and fur-traders found the same race in the valley of the Ohio, on the shores of Lake Superior and at the rapids of Sault Sainte Marie.

Of this race were the Delawares and the Shawnees. The latter were a strange and wandering people, whose location it was always difficult to fix, but who are known to have more than once come into conflict with the French of Quebec. They eventually settled on Canadian soil and played a brief but important part under Tecumseh in the War of 1812. The former were at one time conquered by the Iroquois and compelled to bear the opprobrious Indian name for women, but in one of the French and English wars they recovered at once their courage and their position by espousing the side of the French. Other branches dwelt along the Canadian shores of the Atlantic and in the wastes north of Lakes Michigan, Superior and Huron. The latter tribes included the Ojibways, Pottawatamies and Ottawas, who at one time formed a sort of loose union and offered a temporary but for the time being an efficient check to the course of the Iroquois conquest. In this region also were the Sacs, the Foxes and other smaller divisions of the Algonquin race. Other branches in Nova Scotia were known as the Micmacs, in western New Brunswick as the Etchemins, in Quebec as the Montagnais, and in the Far North as the Nipissings.

The Iroquois or Five Nation Indians stretched across what afterward became the State of New York into Ontario and Quebec, and included the Mohawks, Oneidas, Onondagas, Cayugas and Senecas. Though united in a sort of loose confederacy and by a system of clanship, they seem to have had no clearly defined and continuous ruler, but to have trusted their joint affairs to the central council at Onondaga. And, though numbering only about 4,000 warriors in their day of greatest power, they were able to make the name of the Five Nations a word of terror to all the tribes from Quebec to the Carolinas and from the Far West to the Atlantic shores. To the French and the American colonists they were a continuous source of dread, while to the English forces in Canada at a later period they became an arm of military strength a little difficult to define in degree.

A people not inferior in courage but not nearly so aggressive in character as the Iroquois were the Hurons, whose name is so well known through their intercourse with the French Jesuit missionaries. Their population is estimated by Parkman as having been about 10,000 souls, though other writers place the number at double that figure. In the superior nature of their dwellings, in their manners, cus-



Indians at Calgary, Alberta, Canada

toms and superstitions, they closely resembled the Iroquois. They met destruction at the hands of that great confederacy, and after 1680 disappear from view, except in a few isolated settlements under French protection. The Neutral nation, living along the north shore of Lake Erie and remaining for a long period neutral between the Hurons and the Five Nations; the Andastes, dwelling in fortified villages in the valley of the Susquehanna; the Eries, living in the vicinity of the lake which bears their name, were all of kin to the Iroquois, and were all in time conquered and practically destroyed or incorporated by that most powerful of the savage nations of North America. Then followed the conquest of the Delawares, or Lenapes, and the expulsion of the Ottawas from the vicinity of the great river which bears their name. In 1715 the Iroquois were strengthened by the admission of the Tuscaroras, a warlike people of admitted kinship, to the confederacy, as a sixth nation.

The original population of these various tribes and races and nations of kindred origin can, of course, only be estimated. Garneau, in his 'History of French Canada,' puts the Algonquin total at 90,000 souls, the Hurons and Iroquois together at about 17,000, the Mobiles of the Far South at 50,000, and the Cherokees, of what is now the centre of the United States, at 12,000. His total is 180,000 for the greater part of the continent, and in view of the constant condition of warfare in which they were involved, and the statements of travelers like Cartier, Joliette, Marquette, De la Jonquière, etc., it is probably not underestimated. Even as it is, however, the fact of the dominating power of a few thousand Iroquois during so many years affords an interesting illustration of the effects of military skill and preparedness under savage conditions.

Habits, Customs and Appearance.— In conduct it should be remembered the early Indian was kind and hospitable to the exploring European. The Jesuit and Recollet missionaries, in what is now Canada, bear testimony in many cases to this fact. Hakluyt, in his account of Cartier's first visit to Hochelaga (1535), says that "the Indians brought us great store of fish and of bread made of millet, casting them into our boats so thick that you would have thought it to fall from Heaven." The personal appearance of the Indians, their customs and beliefs, have been often described, and with most varying degrees of accuracy or the reverse. The fact is that changing conditions brought about frequent changes in manners and appearance. The Huron, or Wyandotte, in days when he was a successful rival of the Iroquois, could hardly be recognized in the fearful and unaggressive convert of the missionaries during the years of his final struggle and disappearance. The Delawares, in their period of active life and power, were not the same people as the subject slaves of the Iroquois, nor were the latter in their earlier times of peace and trade like the fiery savages whose conquering warwhoop became a signal of death from the Great Lakes to the Mississippi.

The Indian races of Canada were emphatically the product of nature, however, and amongst them all were similarities which stamped them as of the same origin and as possible descendants of Migrating Tartars from the Steppes of central Asia. They were as a rule tall and slender and agile in form, with faces bronzed by sun and rain and winds. Their expression was stern and sombre, seldom or never marked with a smile. Their heads had high cheek-bones, small sunken and keenly-flashing eyes, narrow foreheads, thick lips, somewhat flat noses and coarse hair. The senses of sight and sound and feeling were developed into a sort of forest instinct which seemed almost supernatural to the first white settlers. Their costumes of deer-skin and moccasins, their necklaces of wampum, beads or shells, their ornaments of feathers and claws and scalps are well known, as is the vermilion paint with which they delighted to daub their faces and bodies. The only weapons they possessed before the Europeans came were the arrow and tomahawk. Hunting and fishing were their occupations, war their pastime. All these pursuits made permanence of dwelling very difficult and involved naturally a life of almost ceaseless wandering.

Religions and Superstitions of the Indian. — Their religion was always a peculiarly mixed quantity. Champlain states that the Micmacs had neither devotional ideas nor ceremonies. Other tribes assured him that each man had his own god whom he worshipped in silence and secrecy. They seem, however, to have all worshipped something — whether the spirit of good, the spirit of evil, the spirit of storm, the god of war, the spirit of the mountains or a spirit of the waters. Sacrifices were not uncommon, and Father Jogues is authority for having seen at least one human sacrifice amongst the Iroquois. How far they really worshipped one Great Spirit is a matter of uncertainty, and it has been claimed that the early missionaries suggested to their minds an idea which they were quick to absorb through the questions and answers naturally given. However that may be, there can be no doubt of their intense belief in spiritual manifestations and interventions. They peopled the very air with friendly or hostile spirits, and raised amongst themselves those powerful manipulators of superstition — the medicine men — to control the surrounding demons of storm and famine, disease and death. To the same men were given the care of the sick, and mixed up with much that was harmful, there were no doubt many simple remedies used supplementary to a mass of incantations and superstitious mummery. Dreams they put great faith in, and oratory held a place of honor secondary only to personal prowess. But the chief of all important customs of the Indians turned upon war and its occasionally brief concomitant, peace. A struggle between two tribes of nations could be brought on by the most trivial cause, or by almost any ambitious and restless individual. When determined upon, it became the source of uncontrollable joy, of wild dances, of eloquent harangues, of multitudinous prayers and sacrifices, of feasts and endless bravado and boasting.

Relations with the French and English.— In the wars between the French and English and Americans which devastated parts of North America during nearly 300 years, the Indians exercised a large influence and, had they been united, might more than once have expelled the white invader altogether. The Indians

found the French more congenial, but preferred the English to trade with, as they paid better prices. In their efforts to secure the suppression of the liquor traffic, the French bishops and missionaries were brought into conflict with the traders, who on their part urged that if they did not obtain brandy (and orthodoxy) from the French they could obtain rum (and heterodoxy) from the Dutch and English. Roughly speaking the Algonquins and Hurons stood by the French, the Iroquois and some minor nations by the English. When the Five Nations had beaten the Algonquins and destroyed the Hurons, they turned their attention to the French, and several times brought the settlements on the Saint Lawrence to the very verge of destruction. After the supremacy of England seemed finally established there existed for some years a sort of brooding trouble. The New England colonists had never treated the Indians upon their borders well, and the result had been a long series of reprisals and wasting war. Greedy traders and unscrupulous speculators in land had robbed the Indians of their intellect by brandy, and of large tracts of land by fraud. The American Colonies, indeed, claimed the whole soil, and without British permission, though in the king's name, made frequent and large grants of Indian territory and then seemed surprised when the tomahawk and scalping-knife were used in response by the untutored savage. Finally, land regulations were made by the home government which to some extent stopped this sort of lawlessness, and were respected in Canada, though more or less disregarded in the Thirteen Colonies as the spirit of local revolt developed. Sir William Johnson, of the Mohawk Valley in New York, was appointed superintendent-general of Indian affairs, and he did his best to enforce these regulations.

When the Thirteen Colonies plunged into revolution the majority of the Indians stood by Great Britain. Those who did not take an active part with the Iroquois stood aloof — with the exception of the Oneidas and Tuscaroras — and refused all the efforts of Congress to obtain their co-operation. At the close of the war (1783) the Iroquois were given large grants of land by the British government and, under the guidance of Joseph Brant — Thayendanegea — the brilliant chief who had led them throughout this period, settled in various parts of the new province of Upper Canada. In 1812 many served again under the British flag, while other nations and tribes were brought together by the martial spirit and influence of Tecumseh — a leader who fills an interesting place in Canadian history. Since then the Indians of Canada, with the exception of a very few who were led astray by Louis Riel in the Northwest troubles of 1885, have lived at peace amongst themselves and with the white men, and have been trying to become accustomed to a life of monotonous civilization and, to them, somewhat degrading labor.

Indians of the West.— The Western Indian, under the long and reasonably wise administration of affairs in what are now the provinces of Manitoba, Saskatchewan and Alberta, by the Hudson's Bay Company, acquired characteristics different from those of other parts of the Dominion. They were not in such a state of tutelage as in Ontario; they were trusted in the matter of supplies and the trust was rarely abused; they became an easy-going, light-hearted people, with something of the white man's shrewdness in trade and all of the native's agility on foot or in a canoe. When the old order passed away in 1871 and the country was acquired by Canada, there was much ferment, but it gradually gave way before the wise treaties, made from time to time, allotting on behalf of the Crown certain reserves which were selected by joint action, on a basis of 640 acres for each family of five, and administered with, upon the whole, fairness and justice by government officials. These treaties were as follows:

No.	Year	District, etc., dealt with	Indians concerned
I.	1871	Province of Manitoba	3,270
II.	1871	Lake Manitoba, Souris and Moon Mountain	2,185
III.	1873	Lake of the Woods, etc. (55,000 square miles)	2,673
IV.	1874	Lake Winnipeg to Cypress Hills (75,000 square miles)	6,886
V.	1875	Lake Winnipeg and river Saskatchewan (100,000 square miles)	3,182
VI.	1876	Plain and Wood Crees. Upper Saskatchewan (120,000 square miles)	6,622
VII.	1877	Blackfeet of Bow River (35,000 square miles)	7,681
VIII.	1899	Peace River Valley (342,700 square miles)	3,733
IX.	1905–06	Indians of the Albany River and James Bay and north of watershed of Lakes Superior and Huron	2,047
X.	1906	Crees and Chippewayans of northern Saskatchewan	723

These Western Indians were, and are to some extent, divided into a series of loose confederacies — the Blackfeet, including the Bloods, Piegans and Blackfeet; the Sioux, including the Stoney or Assiniboine tribe and various branches of the Sioux; the Cree, including the Plain Crees, the Wood Crees and the Muskegon Crees; the Ojibway Confederacy. In British Columbia the Indians at the present time number about 25,000 and are lowest in the scale of the Canadian tribes. They include the Coast Indians and the Mountain Indians and are divided chiefly into the Tinne and Thlinkit tribes and various subdivisions such as the Shuswaps, the Tahlkill, the Tahltan, the Taku, the Kaska, etc. With the Indians of Canada, as a whole, there have been some 1,540 treaties made from time to time and involving the exchange, or sale, of lands, or the relinquishment of claims. The Indian population of Canada as at 31 March 1916 was 105,561, divided as follows: Alberta, 8,682; British Columbia, 25,737; Manitoba, 11,935; New Brunswick, 1,874; Nova Scotia, 2,119; Ontario, 26,305; Prince Edward Island, 302; Quebec, 13,348; Saskatchewan, 9,962; Northwest Territories, 3,769; Yukon, 1,528.

INDIANS, Catholic Education of the. Upon the discovery of America in 1492, the various religious orders of the Roman Catholic Church hastened to send missionaries to the new field. A small school for the education of the natives was an accompanying feature of each mission station, and after Cortes had conquered Mexico, Franciscans, Dominicans and Jesuits in course of time educated and converted the natives to Christianity, and founded missions and schools which exist there to-day, and in California, now an integral portion of the United States, but formerly part of Mexico. North and south the missions and schools were

established and as germs of diocesan organizations bore fruit in the foundation of the see of Caracas in Venezuela in 1531; that of Lima, Peru, in 1539; of Chiquisaca, Bolivia, in 1551; and of Santiago, Chile, in 1561. Brazil was entered in 1500 by Franciscans who were followed half-a-century later by Jesuits. The first Brazilian see was founded at Bahai in 1561; in La Plata, now Argentina, the see of Cordova was founded in 1570, and there in course of time the Jesuits built up a magnificent college. In Central America, Franciscans began their work of education and conversion in Costa Rica in 1560, and during the last 30 years of the century friars labored successfully in Guatemala, teaching the arts of civilized life along with the doctrines of salvation. Early in the 17th century, Jesuit fathers entered Acadia (Nova Scotia) and Canada, and in 1659 the first episcopal diocese in the region was organized at Montreal. Torture and martyrdom did not deter these brave champions and pioneers of Christianity and civilization, and the development of the United States followed the pioneer growth of Catholic congregations and schools among the native Indians. In the first half of the 19th century, the Indian nations of the Rocky Mountains and Northwest Territories (American and Canadian) were pagan. The Jesuit Father De Smet made the long and dangerous journey from Saint Louis, Mo., to the headquarters of the Flathead nation in Montana, inaugurated the introduction of Christianity and prepared the way for the advent of younger members of the order. See CATHOLIC INDIAN MISSIONS IN THE UNITED STATES.

INDIANS, Education of the. Indian education as formerly conducted in the United States was in no way the outcome of any deliberate plan on the part of the Federal government, but was directly descended from the first attempts to teach the Indians of Virginia, and particularly from like beginnings in Massachusetts, where the remarkable results of John Eliot (q.v.) were achieved.

Eliot's Work.— Eliot was actuated by high motives, and his simple measures were chosen with consummate wisdom. Having familiarized himself with the language, disposition and character of his Indians, he secured their confidence and respect. Those who would follow him he gathered in towns, where he taught them the liberties and responsibilities of township government and the devices and institutions of civilized life, among which the Church and the school naturally occupied places of honor. A number of "choice Indian youths" he induced to attend English schools that they might prepare themselves for missionary work among their own people. He was warmly supported by "the corporation for the propagation of the Gospel in foreign parts," by the General Court of Massachusetts, and particularly by Daniel Gookins, the official superintendent of the Indians in Massachusetts. Eliot began his work in 1646. In 1674 there were 14 towns of "praying Indians," whose schools and churches, in the majority of instances, were administered by educated natives, and an Indian college had been founded at Cambridge. Yet in due time this success was swept away by the fears and prejudices which developed under the baneful influences of the Indian wars. Similar successful work under the direction of John Cotton and Richard Bourne in Plymouth colony shared the same fate.

Other Endeavors.— Followers of Eliot in the 18th century were John Sergeant at Stockbridge, Mass., and Eleazer Wheelock in Connecticut and New Hampshire. The work of Sergeant, which involved the establishment of day schools, of a boarding-school and an experimental "outing system," was almost ideal in conception, but ended with the deportation of his Indians to the West. Dr. Wheelock's labors led to the establishment of an effective training school and, indirectly, to the creation of Dartmouth College "for the education and instruction of youths of the Indian tribes in this land in reading, writing and all parts of learning which shall appear necessary and expedient for civilizing and christianizing the children of pagans, as well as in all liberal arts and sciences, and also of English youths and any others." Only the last purpose was destined to achievement.

Surviving Influences.— But in spite of external failure, the spirit and much of the form of these early enterprises persisted. Their impress was until recently observable in almost every prominent feature of the Indian-school organization of the United States, notably in the establishment of day schools in or near Indian villages as a means of domestic and industrial uplifting of Indian family and village life; of industrial boarding-schools in territory occupied by Indians, to introduce among the young a taste for the refinements, duties and responsibilities of civilization; of advanced training-schools in civilized English-speaking communities for the fuller equipment of "choice Indian youths" for full citizenship in such communities, or for missionary work in the ideals, institutions and arts of civilization among their own people. It is still seen in the universal stress in all schools upon instruction in husbandry, certain trades and domestic arts; in the "outing system," which places partially educated Indian girls and boys as paid helpers in suitable English-speaking families, and affords them instruction in the ordinary public schools; and in the importance attached to religious and ethical training.

Wrong Departures.— On the other hand, it is to be deplored that a number of valuable features of the early schools were later abandoned, and even supplanted by opposite tendencies — the unintelligent warfare against the Indian idiom; the introduction of certain brutalities of military discipline; an equally mistaken effort to wean Indian youth from Indian association by throwing contempt upon the Indian and by stimulating a feeling akin to hatred of Indian family ties; and in general a policy of compulsion and repression, rather than a spirit of development and benevolent helpfulness. Serious harm came to government schools because patronage entered as a factor in the appointment of officers and employees. Thanks to the Indian Rights Association, the Mohonk Conference, and a number of other societies, in 1893 civil-service rules were applied to employees of the Indian schools.

History of Organization.— The successive steps in the organization of Indian schools have been as follows: After the Revolution little heed was paid to Indian education for 30 years.

Only minor appropriations are recorded on the basis of treaties with a few tribes. But in the first quarter of the 19th century a religious revival directed attention to Indian education as a Christian and national duty. Congress responded in 1819 with an appropriation of $10,000 in addition to certain treaty obligations. In 1820 the President was authorized to apply this sum annually in aid of societies and individuals engaged in the education of Indians. In 1823 $80,000 was expended in 21 schools maintained by missionary bodies, $12,000 having been granted by the government. In 1825 the number of such schools had risen to 38, their entire expenditure to $202,000, of which the government, directly and indirectly, had contributed $25,000. In 1848 there were reported in operation 16 manual-training schools, 87 boarding-schools and other schools. These schools continued to increase in number and efficiency up to 1873, under the control of missionary bodies, with scanty aid from the government, which had established only a few small day schools directly under treaty provisions. After 1873, however, the government entered upon an era of great activity in the establishment of strictly government schools. In 1877 Congress appropriated for schools, outside of treaty provisions, $20,000; in 1880, $75,000; in 1885, $992,800; in 1890, $1,364,568; in 1895, $2,060,695; in 1899, $2,638,390; in 1900, $2,936,080; 1901, $3,083,403.65; 1902, $3,251,254; 1910, $3,757,909; 1916, approximately $4,500,000. The expenditures have doubled within 20 years, and trebled within 25 years. During the quarter century the average attendance rose in more than like ratio. Increased appropriations naturally stimulated a desire on the part of the government to control expenditures. Moreover, the Constitution, by implication at least, forbids the appropriation of public funds for denominational purposes. Conclusions unfavorable to government support of missionary schools were further strengthened by the fact that the Roman Catholic Church had gradually outstripped the Protestant missionary bodies and was absorbing the lion's share of government support. In 1893 the Methodist Episcopal Church withdrew from participation in government aid, but without abandoning its schools. In 1895 this example was followed by the Presbyterians and Congregationalists; in 1896 by the Friends; and in 1897 by the remaining Protestant denominations. This left only the Catholics in the field with an appropriation, and in 1901 it was withdrawn from them also. In 1894 Congress had declared its policy of abandoning all support of denominational schools, and this policy has gradually been followed out.

The Schools of To-Day.— The present Indian schools under government control are day schools, reservation boarding-schools and non-reservation boarding-schools. These in 1916 numbered 324, including both boarding-schools and day schools; pupils are also maintained by contract in white public schools.

Day Schools.— Day schools in Indian villages or settlements are, as a rule, in charge of a male teacher and his wife, or, as in the Pueblos of New Mexico and in the Indian villages of southern California, of a white woman teacher and an Indian housekeeper. These teachers are usually employed for 10 months in the year; the male teacher's wife acts as housekeeper. The children spend five to eight hours during the five days of the week under the care of these employees, and return to their homes in the evening. The instruction is of the simplest character. The children are taught to speak, read and write English within narrow limits, to cipher, to draw and to sing. They get some rudimentary notions of geography, of natural history and of United States history. The methods are borrowed largely from the kindergarten and from object-teaching and much stress is laid upon habits of cleanliness and order, mutual kindliness and prompt obedience. The boys receive some instruction in the use of tools, in gardening and in some instances in the care of cows. The girls are taught sewing, cooking and other arts of housekeeping. In the poorer Indian communities a noon-day lunch of a few simple articles is furnished. While these day schools accomplish comparatively little in conventional schoolroom work, they serve as concrete illustrations of a civilized Christian home which the Indians learn to respect and, in an appreciable degree, to emulate. Moreover, they reconcile the Indian with the idea of sending his children to school, and render him more willing in due time to entrust them to the care of boarding-schools, as well as more ready to appreciate and to accept the lessons of civilization. The most successful of 215 such schools in 1916 were located in Wisconsin, North Dakota and South Dakota; the least successful, probably, among the pueblos of New Mexico, where the Indians live in a state of half-civilization which they owe to their Mexican and Spanish antecedents, and which fully satisfies their ideals.

Reservation Boarding-Schools.—There were 74 of these in 1916, averaging 136 pupils. They are in charge of a superintendent who also has charge of the reservation activities and is assisted by a matron and such teachers, industrial and domestic helpers as the capacity and character of the school may require. In some cases a principal is in direct charge of the school, relieving the superintendent of the detail of management. In addition to regular teachers, the school is provided with a cook, a seamstress and a laundress, whose office it is not only to supervise their respective departments, but also to instruct the girls in these arts. For instruction of the boys there is a farmer, an industrial teacher, and, at larger schools, a tailor, a shoe and harness maker, a carpenter and a blacksmith. An experiment to provide for more methodical instruction in the use of tools, by expert manual-training teachers, failed because the Indian office would not afford a salary for this position sufficient to attract competent men. In 1894 the experiment of connecting kindergartens with these schools was tried, and proved eminently successful. At the present time there are 26 kindergartens connected with boarding-schools, and the use of kindergarten methods and material has entered the primary classes in practically all these schools with similar good results. In the kindergarten the children spend from one and a half to two hours each half-day. In most of the other schools children spend half a day in the schoolroom, and the other half-day in domestic or industrial work of a character suited to their age. Experience has proved that half-day instruction, at first

forced upon the schools as an expedient, is commended by its good results.

The aim of the schoolroom work is to teach reading and writing within the usual limits of primary work; arithmetic for the needs of ordinary daily life; rudimentary geography and United States history; drawing and singing; the laws of hygienic living; garden and orchard work; and familiarity with the simpler requirements of agricultural and domestic industries suited to the locality. Moreover, in a few of the larger schools, the older boys have much opportunity to acquire skill in carpentry, blacksmithing, tailoring and shoemaking. These institutions are to the children not only school, but home and community. The institution gives them shelter, food and clothing; it accustoms them to habits of cleanliness and decency; it cultivates their æsthetic tastes; it labors to secure right moral attitude, and in its Sunday-school seeks to stimulate the religious life of the children.

In 1893, under civil-service regulations, there came some improvement. Still with reference to minor employees the superintendents, and even the Indian office, were powerless and frequently good superintendents were forced out of service by combinations against them among the appointees of the agent, or through the aid and influence of unscrupulous partisan inspectors or supervisors. But in 1896 all employees of the school service were placed under civil-service protection, and since that time there has been marked improvement in the conditions and work of these schools. To a certain degree these evils still persisted, however, because of the power and political bias of the agents; but of late the government has adopted the policy of replacing the agents with bonded school superintendents. There has been decided gain in the equipment, in the sanitary condition, in the general character of employees and in the conduct of the schools. For the Indian office, relieved of attention to office-seekers and their patrons, has been enabled to pay increased attention to the schools themselves. In the reservation boarding-schools instruction continues through 40 weeks; but often some children are kept at the school throughout the year.

Course of Study.— In 1916 a decided step forward was taken by the adoption of a new course of study for Indian schools, covering 10 grades. The predominant feature under this course of study is industrial instruction. The first three years of the course are devoted to primary work. The next three years are spent in prevocational training, and the last four years to vocational training in which instruction in agriculture and allied subjects and household arts is given a prominent place. As a general rule the work of the day schools is limited to the first three years of the course, that of the reservation boarding-schools to the first six years, while in only some of the non-reservation schools is the full 10-year course, with its allied vocational training, given.

Non-Reservation Boarding-Schools.— Of these there are 25. The superintendents of these schools are bonded and directly responsible to the Indian office. The schools are, as a rule, located at a distance from the Indian country, and in the vicinity of American towns which afford contact with the amenities of civilized life. Members of many different tribes are also brought together, and tribal antagonisms are broken down. The pupils are older than those at reservation schools, and some have had previous training in day schools or reservation boarding-schools. Because far away from their Indian homes, and near to English-speaking communities, they gain a better control of English; classroom work reaches far into the advanced grammar-school courses of study, with special stress upon language practice, arithmetic, geography, history, nature study, drawing and civil government. Instruction in domestic and industrial arts is made effective by frequent opportunities directly to observe their practical applicability and value. The principal reservation schools are at Carlisle, Pa.; Lawrence, Kan. (Haskell Institute); Chilocco, Okla.; Albuquerque and Santa Fe, N. M.; Phœnix, Ariz.; Riverside, Cal. (Sherman Institute); Chemawa, Ore.; Tacoma, Wash. (Cushman); Rapid City and Flandreau, S. D.; Genoa, Neb.; Pipestone, Minn.; and Tomah, Wis.

Contract Schools.— In addition to maintaining these strictly government schools, the Indian office up to 1901, as before said, paid by contract for the education of many hundreds of Indian pupils distributed in Catholic mission boarding-schools, at Lincoln Institute, Philadelphia, and at Hampton Institute, Hampton, Va. In the appropriation for that year, the aid was withdrawn from all but the last-named, where 120 pupils were contracted for. Besides these, the government since 1891 has endeavored to place Indians in white public schools where there are many whites and few Indians, as the most rapid means of civilization. The antagonism of local or State authorities to this coeducation has been gradually overcome and the number of children so enrolled is rapidly increasing.

Supervision.— Direction of the Indian schools rests with the Indian office, which is under the supervision of the Secretary of the Interior. In the Indian office the details of the work are entrusted to the education division, to which all reports are made, and by which all directions and orders are drafted and issued. The education division is aided in its work by a force of supervisors and by 21 supervising superintendents. The supervisors act in a general inspecting capacity, and the supervising superintendents are charged with the direct supervision of the schools and the work of the new course of study, particularly the industrial instruction. These supervisors and supervising superintendents have an advisory rather than an administrative status. They consult with the superintendents and employees charged with the duty of giving instruction and report to the commissioner of Indian affairs the extent to which the various schools reach or fall short of reaching the ideals of the course of study, at the same time making recommendations as to the changes needed to raise the standard of the schools.

Schools.— The schools of the so-called "Five Civilized Tribes" of Oklahoma are not included in the above sketch. The five tribes in 1916 included 41,824 Cherokees, 26,828 Choctaws, 18,774 Creeks, 10,966 Chickasaws and 3,127 Seminoles. Missionary zeal had early availed itself promptly of this field for its efforts. Substantial boarding-schools were

erected, more particularly by the Presbyterians, Methodists and Baptists. In due time, however, the Indian authorities began to make appropriations for these schools. Ultimately they took entire charge of them. Unfortunately, administrative affairs were largely in the hands of whites, who, by intermarriage or bribery, had been adopted into the tribes and there came over the schools, as well as over all other public interests, the blight of extreme partisanship and nepotism, which rapidly degraded them in character and efficiency. In 1898 the government at Washington assumed supervisory control over the affairs of all these tribes except the Seminoles. The conduct of the schools and orphan asylums in the four tribes involved was placed under the direction of a superintendent of schools in Indian Territory, appointed by the Secretary of the Interior. Under him there was for each of the tribes or nations a supervisor of schools, whose duty it was to inspect the educational institutions in his district and to assist in their organization and conduct. The superintendent reported to the commissioner of Indian affairs at Washington through the United States inspector for the Indian Territory, who was his immediate superior. The initial report of this superintendent showed in the four tribes 24 boarding-schools, with an enrolment of 1,758 pupils and an average attendance of 1,480, taught and cared for by 234 employees at an annual expense of $236,824. These schools have now been made a part of the general system of schools, except that with the exception of the Cherokee Indian Training School, they are supported by tribal funds of the different tribes and are under the direct supervision of a supervisor for the Five Civilized Tribes. In 1916 there were 10 such schools, enrolling 1,227 pupils in charge of 147 employees. In 1916 there were also 590 pupils enrolled in schools maintained in the Five Tribes' territory and known as mission schools under contracts calling generally for a per capita of $108, but in the cases of two such institutions of $120.

INDICAN, a colorless substance chemically related to indigo, found in wood, in most plants yielding indigo-blue, and in human urine.

INDICATOR, in steam engineering, an instrument invented by James Watt, to record, graphically and automatically, the pressure in an engine cylinder at every point of the stroke. By means of the diagram that the indicator draws, it is possible to determine whether the valves of the engine are working correctly or not, and it is also possible to estimate the horse power that the engine is developing with considerable accuracy. Commercially, the steam-engine indicator may be had in many forms; but all are based on the same fundamental principle, which will be understood by reference to the diagram presented in Fig. 1. The paper upon which the indicator diagram is to be drawn is here supposed to be secured, flat, to a carriage which travels back and forth upon a track; the motion of the carriage corresponding precisely to the motion of the piston of the engine. In practice it would be inconvenient to have the carriage travel a distance equal to the whole stroke of the engine, and hence some form of reducing motion is used, so that the motion of the carriage may follow the motion of the engine piston accurately, but with materially reduced velocity. The indicator diagram is drawn by means of a pencil-point carried on the piston rod of a small steam cylinder which is situated below the carriage, and which opens freely into the cylinder of the engine from

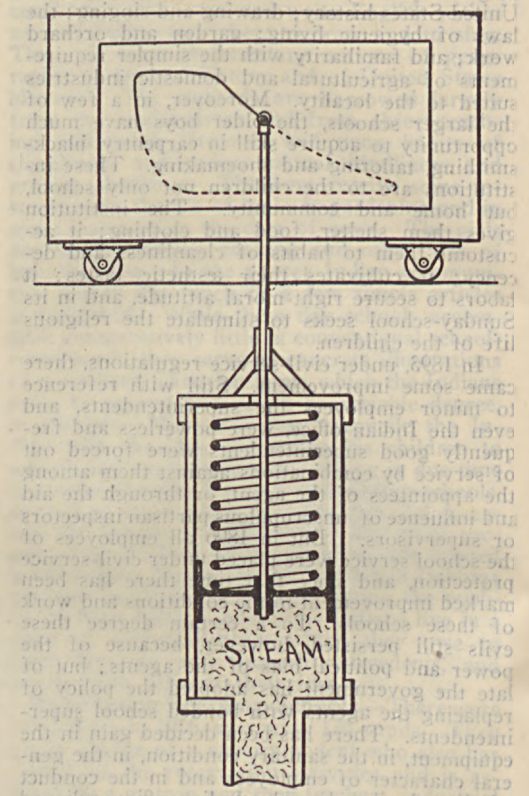

Fig. 1.

which the diagram is to be taken. The piston of the indicator is pressed downward by means of a spring whose strength is accurately known, so that the increase of pressure corresponding to a rise of one inch in the position of the pencil-point is known. When the indicator is in operation, the pencil rises and falls proportionately to the pressure of the steam in the

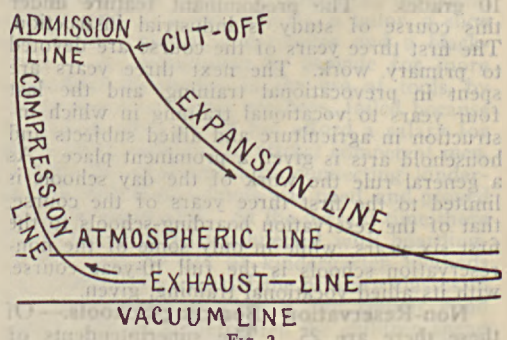

Fig. 2.

engine cylinder, and the carriage, with its attached paper, travels back and forth horizontally, at the same time, keeping pace precisely with the motion of the piston of the engine. Under these circumstances the pencil-point traces a diagram somewhat like that shown in the illustration. In practice, the paper upon which the diagram is drawn is usually wrapped about a cylindrical drum, which by rotating presents a new surface of paper for a new diagram. It follows the motion of the engine piston just as the carriage here shown. In Fig. 2 an enlarged view of an indicator card (or diagram) is given, together with the technical names of some of its more important parts. The arrows show the direction in which the pencil travels as the diagram is drawn. The "admission line" is the part that is drawn while the engine is in full communication with the boiler, and drawing steam from it. The angle marked "cut-off" corresponds to the instant at which the steam supply is cut off, and the expansion of the steam begins. The "expansion line" is drawn during the expansion of the steam; and on the return stroke, after the exhaust valve has opened, the "exhaust line" is drawn. When the exhaust valve has closed again, the steam remaining in the engine cylinder is compressed until the end of the stroke, the indicator meanwhile drawing the "compression line." The "atmospheric line" is the straight, horizontal line drawn by the engine when the connection is broken between the engine cylinder and the indicator cylinder, and the latter is open freely to the air. The "vacuum line" is the line that would be drawn by the instrument under like circumstances, if a perfect vacuum could be maintained in the indicator cylinder. The "vacuum line," of course, must be drawn in by hand. It is parallel to the "atmospheric line," and at a distance below it corresponding to a pressure of about 14.7 pounds per square inch, on the scale to which the diagram is drawn. The diagram shown in Fig. 2 refers to a condensing engine. In a non-condensing engine, the exhaust line would not be lower than the atmospheric line, and would, in fact, be above it, if there were any sensible back-pressure in the engine during exhaust.

A considerable number of other mechanisms are termed indicators, as the stock-indicator, a receiving telegraph instrument that prints on an endless tape the figures, etc., of stock sales telegraphed; telegraph indicator, a telegraphic instrument having a vertical needle making indications on a dial, called also needle telegraph; circuit indicator, an upright galvanometer or the like for indicating the presence and character of an electric current; speed indicator, a gauge having usually a dial and pointer for indicating visually the speed of a machine, etc.; track-indicator, a registering device for mounting on a railway car or locomotive to record the variations of the track from accurate level and alignment.

For detailed information concerning the steam-engine indicator and its uses, consult Pray, 'Twenty Years with the Indicator'; Peabody, 'The Steam Engine Indicator'; also, for less extended treatment, any good book on steam engineering.

INDICTION, a period or cycle of 15 years. The origin of indiction as a chronological period is not known. Several writers have propounded theories explanatory of its origin, none of which are supported by any evidence. In the time of Athanasius it came into favor among ecclesiastical writers. Being adopted by the Popes, it came into general use during the Middle Ages. The time from which reckoning by indictions began is, according to some, 15 Sept. 312; according to others, 1 Sept. 312; but when this method was adopted by the Popes, it was ordered to be reckoned as beginning 1 Jan. 313. The latter only is now used, and is called the Papal Indiction. If we reckon backward to the beginning of the Christian era, it will be found that 1 A.D. corresponds to the fourth year of an indiction—hence, if to any given year of the Christian era three be added, and the sum divided by 15, the remainder will give the position of that year in an indiction—e.g., 1918 was the first year of the 108th Papal Indiction.

INDICTMENT, ĭn-dīt'mĕnt, a formal written charge made before a legal tribunal against an accused person or persons. The essential requisites of a valid indictment are—first, that the indictment be presented to some court having jurisdiction of the offense stated therein; second, that it appear to have been found by the grand jury of the proper county or district; third, that the indictment be found a true bill, and signed by the foreman of the grand jury; fourth, that it be framed with sufficient certainty; for this purpose the charge must contain a certain description of the crime or misdemeanor of which the defendant is accused, and a statement of the facts by which it is constituted, so as to identify the accusation; fifth, the indictment must be in the English language, but if any document in a foreign language, as a libel, be necessarily introduced, it should be set out in the original tongue, and then translated showing its application, 6 Term. 162. The formal requisites of an indictment are: First, the venue, which at common law should always be laid in the county where the offense has been committed, although the action be in its nature transitory, as in case of a battery. The venue is stated in the margin thus: "City and County of ——, to wit." Second, the presentment, which must be in the present tense, and is ordinarily expressed in the following formula: "the grand inquest of the State of ——, inquiring for the city and county aforesaid upon their oaths and affirmations present". Third, the name and addition of the defendant; but in case an error has been made in this respect, it is cured by the plea of the defendant. Fourth, the names of third persons, when they must be necessarily mentioned in the indictment, should be stated with certainty to a common intent, so as sufficiently to inform the defendant who are his accusers. When, however, the names of third persons cannot be ascertained, it is sufficient, in some cases, to state "a certain person or persons to the jurors aforesaid unknown." Fifth, the time when the offense was committed should, in general, be stated to be on a specific year and day. In some offenses, as in perjury, the day must be precisely stated, but although it is necessary that a day certain should be laid in the indictment, yet in general the prosecutor may give evidence of an offense committed on any other day previous to the finding of the indictment. Sixth, the offense must be properly described. This is done by stating the substantial circumstances necessary to show the nature of the

crime, and next the formal allegations and terms of art required. As to the substantial circumstances: the whole of the facts of the case necessary to make it appear judicially to the court that the indictors have gone upon sufficient premises should be set forth; but there should be no unnecessary matter, nor anything which on its face makes the indictment repugnant, inconsistent or absurd.

According to the rules of pleading in criminal actions at common law there are certain terms of art used, so appropriated by the law to express the precise idea which it entertains of the offense, that no other terms, however synonymous they may seem, are capable of filling the same office; such, for example, as traitorously in treason; feloniously in felony; burglariously in burglary; maim in mayhem, etc. In New York, and in nearly all of the States which have adopted the code system, the common-law rules of pleading in criminal actions have either been greatly relaxed or entirely abolished. Many of the statutes of the subject are similar to the New York statute, Code Crim. Pro. § 273, which in substance provides that all common-law rules of pleading are abolished, and the forms of pleading prescribed by the code shall be substituted, and § 275 of the same code provides that all an indictment must contain is the title of the action, specifying the name of the court to which the indictment is presented, and the names of the parties, together with a plain and concise statement of the act constituting the crime, without unnecessary repetition. It is also provided in § 283 of the New York Code Crim. Pro. that words used in a statute to define a crime need not be strictly pursued in the indictment; but other words conveying the same meaning may be used.

INDIFFERENTISM, a system or state of indifference; specifically in metaphysics and ethics, the theory of a school of philosophers that the human will acts in utter indifference to all motives, and chooses merely as a judge decides. It is opposed to determinism. See Ethics; Free Will.

INDIGESTION. See Dyspepsia.

INDIGIRKA, in'dye-ger'ka, a river of Siberia, in the government of Jakutsk. It rises in the Yablonoi Mountains and after a northerly course, estimated at 850 miles, through a frozen desert past a few villages, falls into the Arctic Ocean in lat. 71° N., and long. 150° E. It is closed to navigation during the winter months.

INDIGO, the name of a genus of plants, and of the blue coloring matter obtained from them. The indigo plants are tall herbs of the pea family, forming the genus *Indigofera,* of which there are several color-yielding species in various warm parts of the world. The one yielding the indigo of commerce, and formerly extensively cultivated, is *I. tinctoria,* which is native to India, grows five feet high and has pinnate leaves. The coloring matter most abounds in the leaves, and especially at the time of flowering, and that is the time when the crop is gathered by cutting down the plant, and making immediate use of the green stems or foliage, or by drying them for subsequent treatment. This coloring matter is a chemical substance called *indican,* the glucoside of indoxyl, which is converted by oxidation into indigo. Until the discovery of the sea-route to India the only blue vegetable dye available in Europe was that derived from the woad (q.v.), which was limited and costly; this dye-substance was therefore regarded as one of the most valuable of new commodities and a large capital was soon invested in its cultivation in India, Ceylon, China and other regions, where a profitable industry continued until after the middle of the 19th century. The indigo is obtained by macerating the leaves and stems in vats for several hours. Fermentation arises and the water becomes clear yellow. It is then run off into a lower basin, where it is subjected to incessant agitation and gradually turns green, whereupon the indigo begins to form in flakes and settle. The residuum is then thoroughly boiled, filtered through linen, molded into small cakes, and dried. The best quality comes from Bengal and eastern India. Indigo plantations were made with more or less success in Brazil, Central America and Mexico; and one of the foremost inducements held out to settlers in the southern colonies, from Maryland to Louisiana, was the probability of its successful cultivation there. The experiments never yielded results of much importance, partly because crops of tobacco, cotton and foodstuffs were more profitable. Since the discovery of cheap methods of forming blue dyes from coal-tar the cultivation of indigo has declined greatly, but still supplies a steady demand from cloth-dyers who wish an imperishable blue of certain tints.

The wild indigo of the United States is any of several species of a closely related genus *Baptisia,* which flourishes especially in the Southern States. The best known is the yellow-flowered false indigo (*B. tinctoria*), or indigo brown, from which country people obtain a blue dye and a domestic medicine.

Indigo Dyeing.— Before it can be employed in dyeing, the indigo must be brought into solution; and as indigo itself is insoluble, it must be first transformed into a soluble substance, so that it can penetrate the pores of the cloth, where it is subsequently again restored to the form of indigo. To bring the indigo into solution it is ground up to a soft paste with water, after which it is thrown into vats along with ferrous sulphate, slacked lime and water. The ferrous sulphate reacts with the lime to form calcium sulphate and ferrous oxide, the latter being immediately oxidized at the expense of part of the oxygen of the indigo, which in its turn is reduced to a substance called indigo-white. This dissolves in the presence of excess of lime, and the fabric to be dyed is dipped into the vat after the liquid in it is clear. On removing the fabric the indigo-white which has penetrated its pores is reoxidized by the air to indigo-blue; and by repeating this treatment a shade of blue of any desired depth may be obtained. The dyed fabric is finally passed through dilute acid to remove any adhering lime or ferric oxide. Indigo appears to exist in the plant in the form of a glucoside known as "indican," which has the formula $C_{52}H_{62}N_2O_{34}$, and to be developed from this glucoside in the course of the fermentation by the action of a special bacillus, which closely resembles the bacillus of pneumonia. Indigo is now made artificially, the total production of synthetic indigo being probably about one-fourth of the world's consumption. Although artificial indigo-blue appears to have the same chemical formula ($C_{16}H_{10}N_2O_2$) as the natural product, and to be identical with it in every way, it is more expensive than the natural product at the present time. If it could be made more cheaply it would work as great a revolution in dyeing as did the introduction of alizarin in the place of madder. See Coal Tar Colors and the references there given.

INDIGO-BIRD, a numerous and beautiful North American finch (*Passerina cyanea*), the male of which is dark greenish blue, while the female is grayish brown. They are migratory, but in summer spread over most of the United States, placing their neat nest and unspotted bluish eggs in garden bushes as well as in wild thickets. The male has one of the brightest and most persistent songs of any American bird, and he is easily habituated to captivity.

INDIGO SNAKE. See Gopher Snake.

INDIRECT DAMAGES, claims for damages not directly inflicted by the illegal act complained of, but by other causes themselves due to that act. The great historical case is that of the United States claim for many hundreds of millions of dollars' worth of loss, resulting from Great Britain's bad faith or carelessness in letting the *Alabama* (q.v., and Alabama Claims) escape from her ports to prey on our commerce. It was alleged that aside from the actual loss to our shipping and cargoes, we had been damaged to a far greater extent by the resultant effects, chiefly of three sorts: (1) The prolongation of the Civil War due to the encouragement given to the South and the straitening of the North. (2) The destruction of commercial lines and relations, which took long to recover after the war. (3) The raising of the rates of marine insurance. As these claims exceeded the cost of a war plus the indemnity we should have exacted if victorious, Great Britain refused to consider them; and the commission threw them out altogether as contrary to international law.

INDIRECT ELECTIONS. See Elections; Electoral Qualifications; Congress.

INDIUM, in organic chemistry, a metallic element of a silver-white color, discovered by Reich and Richter through spectroscopic analysis during 1863 in the Freiberg arsenical ores. It is very rare. It is related to cadmium and zinc, and both are associated with it in nature; but it is found in many ores beside, although especially in zinc blende. This metal is obtained by heating the oxide with carbon and by other methods. It is soft, malleable and easily fusible. Its distinguishing property, however, and the characteristic which led to its discovery, is the indigo-blue line which all its compounds — so far as investigated — show in the spectroscope. The spectrum of indium exhibits two characteristic lines: one violet line α, and another blue line β; and besides these two fainter blue lines are visible if the burner in which the metal is volatilized be fed with hydrogen instead of coal gas. This metal is obtained by heating the oxide with carbon and by other methods. Its specific gravity is 7.1–7.4; its symbol In; and its atomic weight 114.8. It melts at 174° C. (= 345° F.). Chemically, indium resembles aluminum and gallium, being chiefly trivalent.

INDIVIDUAL PSYCHOLOGY. This term is applied to that branch of psychology which deals with the mental variations of individuals from one another. It is thus contradistinguished from general psychology, which undertakes to determine the facts and laws of conscious processes as a whole and without special reference to their peculiar manifestations in any particular persons or group of persons. The field of individual psychology may be regarded as a part of the larger field of variational or differential psychology in which are to be included studies upon special races and upon social groups of various sorts. Such studies are carried on with special reference to detecting and describing the characteristic mental traits of such groups, but often with little emphasis on typical variations from other similar groups. Obviously the range of problems in individual psychology must be as broad as mind itself, for persons may vary in regard to any mental characteristic. It will only be practicable to mention a few of the problems thus far investigated, e.g., mental type, temperament and genius, the psychology of special mental defect, the psychology of the criminal, the psychology of sex, and that of professions or classes with their peculiar variations of mental constitution.

To exhibit more concretely the kind of material with which individual psychology works we may comment briefly on the first three of these topics. The determination of *mental type* is a problem of individual psychology in the narrow sense of the term in so far as it has to do with the ascertaining of the characteristic features of the mind of any particular person. In so far as it bears on the problem of discovering what actually are the typical groupings of such characteristics among people in general, it obviously belongs to the broader field of variational psychology.

1. Minds may differ from each other as regards the delicacy or sensitiveness with which they respond to stimulations of the sense organs. One may be more sensitive than another to slight variations in temperature, in color, in tone, etc. As a matter of fact, among normal persons such differences of sensitivity are relatively slight when the conditions of training and discipline are similar. As a general rule the higher mental functions show more variation than the lower one such as sensitivity. Minds may differ as regards the special form of sense material toward which they manifest a predilection, e.g., the musically minded person not only finds sounds of greater emotional interest than the unmusical person, but he also has a better memory for auditory experiences and his conscious processes in their entirety are likely to be much more influenced by auditory factors. A further development of such mental preference for one or another kind of sense material is found in the fact that certain individuals carry on most of their thought processes in terms of visual images, whereas others employ auditory images, and still others motor images. Probably the normal condition is represented by an admixture of various forms with some particular group dominating slightly over the others. Again, in memory we

meet striking differences in addition to those of the imagery type already mentioned. For example, certain persons learn very rapidly and also forget rapidly. Others learn with difficulty but retain well that which they have learned. Occasionally we find persons who combine ability to learn quickly with capacity to retain permanently. It seems certain from psychological investigations that individuals supposed to possess particularly good memories are generally proficient only in certain directions. A universally efficient memory is rarely, if ever, found. People differ also very markedly as regards their ability to concentrate their attention. Some persons can concentrate very intensely for a short time but must then rest. Others are able to focalize for more extended periods, and still others find it all but impossible ever to secure any intense concentration. Variations of a striking kind are also disclosed in the formation of judgments. Certain persons judge almost entirely in accord with the objective facts presented to their notice. Others are influenced in various degrees by subjective influences and show themselves peculiarly susceptible to suggestion. It is a matter of common observation that persons vary radically as regards temperament and feeling. One of the most practically important variations is represented by the difference in the rate at which the conscious processes proceed. Just as certain persons naturally walk and talk more rapidly than others, so do the mental processes vary as regards the speed with which they occur. Psychologists have demonstrated a rather characteristic daily variation as regards both rate and efficiency of mental activity. Many persons work best at night. Others are morning workers and still others afternoon workers.

2. The old familiar classification of temperament recognizes the four types: sanguine, melancholic, choleric and phlegmatic. Both the choleric and the sanguine are supposed to be subject to rapid oscillations of emotional interest, but with the sanguine individual, interest is rarely intense, whereas with the choleric it is rarely anything else. The melancholic and the phlegmatic represent the more persistent and dogged forms of interest but, like the previous pair, are distinguished by differences in the intensity of the interest, the phlegmatic person being less, the melancholic more, intense. These classifications are likely to be extensively revised by current investigation.

3. The modern study of genius has not only contributed to a more definite conception of the nature of genius and the general mental characteristics of the remarkable individual, but it has also revealed the hereditary character of marked intellectual superiority, and the relation between certain types of genius and mental defect.

Galton has gathered statistics to show that the frequency of genius is related in a definite and orderly way to the total number of persons in any given group. He has also shown that the genius appears with a background of heredity which affords a reasonable explanation of his peculiar characteristics. The view often urged by such writers as Lombroso that genius is essentially a morbid and degenerate mental phenomenon seems to be sound only in so far as concerns the *liability* of persons of remarkable mental qualities to nervous derangement of various sorts. That insanity itself and genius are in any intrinsic sense identical is not generally granted. Among the interesting problems which deserve further study in the case of genius may be mentioned the determination of the extent to which the genius owes his superior endowment to heredity, as contrasted with education and favorable nurture; the ascertainment of the conditions which hinder or encourage the development of genius; the discovery of the general mental types to which the various remarkable individuals conform.

JAMES ROWLAND ANGELL,
President, Yale University.

INDIVIDUALISM, a regard for and emphasis of the individual. A belief in personal independence and self-sufficiency. In ethics, those doctrines which dwell upon individual welfare rather than social welfare, and determine their standards of conduct by the dictates of individual feeling. Under these views, it is taken for granted that if each individual seeks his own highest welfare, social welfare will take care of itself. Individualism is opposed to socialism and finds defense in the works of John Stuart Mill and Herbert Spencer. It becomes the duty of the state, under this conception, not to interfere with the individual except when it is necessary to preserve the opportunity for action. The function of the state is regarded as an artificial restraint, while individual initiative is a natural factor in evolution. From an economic point of view individualism favors the policy of *laissez-faire* (q.v.). Consult Domisthorpe, 'Individualism: A System of Politics' (London 1889); Eliot, C. W., 'Conflict between Individualism and Collectivism in a Democracy' (New York 1910); Fite, W., 'Individualism' (ib. 1911); Fournière, 'Essai sur l'individualisme' (Paris 1901); McKechnie, 'The State and the Individual' (Glasgow 1896); Tufts and Thompson, 'The Individual and his Relations to Society, as Reflected in British Ethics' (Chicago 1898).

INDIVIDUALITY, a separate and distinct existence. The fact that one thing may be distinguished from all others gives individuality its meaning. Whether the distinction is only relative or is absolute is disputed among philosophers. The problem arises out of the difficulty of thinking of any distinctive character of an individual, except its location in space or time, without using general concepts. With Plato the universals alone were real. With Aristotle reality was found in the concrete individual and the universal stood only for an abstraction. The same problem occurs in mediæval times, in the discussion of the relation of God, Trinity and man, and in modern times in the question of the relation of the individual to society. For other views of individuality consult Driesch, 'Science and Philosophy of the Organism'

(London 1908), and Huxley, 'The Individual in the Animal Kingdom' (Cambridge 1912).

INDO-CHINA, the southeastern peninsula of Asia, formerly known as Farther India, including Anam, Burma, Cambodia, Cochin-China, French Indo-China, Tongking (qq.v.) and other districts.

INDO-CHINESE, generic name of the native population of Farther India, most of whom belong to the southern branch of the Mongol division of mankind, and speak monosyllabic toned languages of the Indo-Chinese linguistic family. They came partly from the Tibetan plateau (Burmese, Arakanese), and partly from South China (Shans, or Laos, Siamese, Annamese). Besides these there is a considerable Caucasic element, numerous especially in Cambodia, where the dominant people are the Khmers of polysyllabic untoned speech. To the same element belong also the Chams of Lower Cochin-China, perhaps the Talaings of Lower Burma, and numerous smaller groups on the eastern coast range, and along the uplands between the peninsula and South China. Like Hindustan, Farther India has a history of primitive civilization. (For details see ANAM; BURMA; COCHIN-CHINA; SIAM). Consult Clifford, H. C., 'Farther India' (New York 1904).

INDO-EUROPEANS. See ARYAN RACE; ARYAN LANGUAGES; INDO-GERMANIC LANGUAGES; IRANIANS; IRANIAN LANGUAGE AND LITERATURE.

INDO-GERMANIC LANGUAGES comprise that group of languages which took their rise in India and Iran and which now, by common consent, with a few slight exceptions, include all the tongues spoken in Europe. There are seven principal branches coming under that head, namely: (1) Germanic; (2) Slavo-Lettish; (3) Celtic; (4) Italic; (5) Greek; (6) Iranian; (7) Indic. It is beyond question that all these idioms together are descended from one common root, the Aryan proper. Internal evidence in favor of this statement is too strong to be rejected. The structure shows it; the stock of words shows it; the number of features in common show it; and finally the sounds themselves show it. Comparative philology has demonstrated beyond cavil that only by assuming a common origin can the fact be accounted for that the most ordinary words and the basic part of grammar — the rough framework of language so to speak — are practically identical; such as the personal pronouns, nouns like mother, father, brother and sister, the earliest domesticated animals and the most indispensable primitive foods and appliances, as the plow; the most necessary verbs, particularly the auxiliaries. The differences between the several languages belonging to the Indo-Germanic, or Aryan, group, as, for instance, between Russian and German, Polish and English, Italian and Lithuanian, are many, in varying degree, but are simply somewhat greater than those, let us say, between cognate idioms, such as Dutch and German, French and Italian, Czech and Jugoslav, or Hindu and Persian. Or rather, the degree of similarity differs. But the structural similarity between all is undeniable. All Indo-Germanic languages, too, are inflectional.

It is agreed that the entire body of the Aryan languages is derived originally from monosyllabic elements, and that of these there were two classes, verbal and pronominal, and that combining these two grammatical forms there arose gradually the rudiments of grammar and of vocabulary. In some of the Aryan tongues there have lingered forms which in the others had disappeared at an earlier date, such as the dual; the future of the verb came later and was made up with auxiliaries; the imperative existed at first only in the second person. Verbs in all of these idioms were originally of primitive structure; some of the refinements of grammar, such as the subjunctive, are doubtful in their derivation; declensional inflections, on the other hand, were in olden days rather more complicated, having three numbers and eight cases, including one denoting instrumentality and one locative; sex distinctions, too, were indicated by the endings of cases. From this complex stage the tendency has been throughout toward simplification. Relative pronouns were late in appearing, growing out of demonstratives or interrogatives; articles came to view not until a late period; numerals for long ran only up to 100. Of all the Indo-Germanic, or Aryan, tongues Sanskrit has preserved most of the original standards. Many, nay, the largest part of the changes wrought were due to phonetic influences, such as in English *sing, sang, sung, song;* or as in Latin *fid, fido, foedus;* in the Greek *λειπω, ελιπον λέλοιπα.*

Necessarily, the close correlation of the Indo-Germanic idioms presupposes a common origin, the existence at some remote period of one united, and in numbers and territory held, rather limited mother tribe, within which the root idiom must have had time to grow and develop. Not only is there linguistic proof of this of the strongest kind, but the further fact that there was a common cycle of sagas, myths and legends of prehistoric heroes, of folklore and of archaic godlike beings worshipped, tends altogether in the same direction. Again, that the Indo-Germanic race derives from the same parent tree is proved by the indisputable fact that it is this race which throughout all historical time has been pre-eminent; first, the Persian, next the Greeks and Romans, and then the nations of modern times. In the main they did this because possessing the same set of qualities.

All the records, however, available do not go farther back than about B.C. 3000, and indicate the Pamir region or the Punjab as the pristine home of the Indo-Germanic stock. The Vedas in their most ancient portions are not older than 2000 B.C. A number of Indo-Germanic idioms amalgamated with others, or disappeared, like Gallic, Etruscan, Burgundian, Scythian, Mesapian, Pelasgian.

INDOOR BASEBALL, a variety of the regular game, played indoors as the name indicates. It is played in a hall at least 40 × 50 feet in extent, with a white ball not over 17¼ inches in circumference. If space does not permit, two outfielders are dispensed with, leaving seven men on a side. The maximum diameter of the bat is 1¾ inches. The rules are similar to those governing the outdoor game with the exception of the limitations imposed by the walls, floor, etc. The special sizes of bat and ball are designed to make the chances and conditions in the game approach as closely as possible those of the regular game. The National Indoor Baseball Association formulates the special rules governing the sport. Consult 'Indoor Baseball Guide' (in Spalding's Athletic Series,' New York, annually).

INDORE, in-dor', India, a Mahratta native state in the Central India Agency. It has an area of 9,469 square miles, covered with great forests, in which many large wild beasts roam. It is watered by the Nerbudda River and is crossed by a portion of the Vindhya mountain range. The land produces, in addition to the valuable timber of the forest areas, cotton, tobacco, sugar-cane, maize and wheat. Opium is also produced in large quantities. Title to the land rests in the state, which rents it to the population. A portion of the population, the Bhils, is the wildest and least cultured of India. The state is ruled by the Holkar. The chief centres of population are Rampura, Mehadpur, Mhow and Bhampura. Pop. 1,004,569. The capital is Indore, a city 440 miles east of Bombay, at the confluence of the Khan and Saraswati rivers. It contains the palace of the Holkar, government buildings, a mint, military barracks and Daly College. It has a good water-supply system and a modern sewage system. Cotton is manufactured. There is a large trade in opium, grain, tobacco and other products of the region. A region in the suburbs has been allotted by treaty to the British resident agent and his staff. Pop. 44,947.

INDORSEMENT, *in law,* the act of writing or printing on the back of a written instrument, or that which is written or printed thereon. It is more particularly applied to the signature usually on the back of a negotiable instrument by which the title thereto is passed. Such signature must be that of the legal holder of the instrument, which must be delivered, or else be acquired by a bona-fide holder, to make it valid. A holder who places an indorsement on a negotiable instrument thereby assumes the obligation to pay the amount therein named if payment has been refused after being duly demanded, provided due notice is given him of the previous dishonor of the instrument. An indorsement is in blank when the indorser signs his name only; an indorsement is special when it specifies the person to whom or to whose order the amount named in the instrument is to be paid. An indorser can avoid personal liability by adding "without recourse" to his indorsement.

INDRA, a Hindu deity especially worshipped in the Vedic period of the Hindu religion, but had great legendary popularity also in the Epic and Puranic periods. In old Vedic poetry he is represented as a mighty ruler of the bright firmament and his principal feat is the conquest of the demon Vr'itra, a symbolical personification of the cloud which obstructs the clearness of the sky, and withholds the fructifying rain from the earth. Indra is the upholder of heaven, earth and firmament and the god who has "engendered the sun and the dawn"—the Jupiter Pluvius of India. See INDIA-RELIGION; VEDIC LITERATURE; and consult Dawson, 'Hindu Mythology' (London 1879); MacDowell, 'Vedic Mythology' (Strassburg 1897), and Wilson, 'Hindu Mythology' (new ed., London 1900).

INDRE, France, a department of central France, once included in the old divisions of Berry, Orleanais, Marche and La Touraine. It has an area of 2,664 square miles; is watered by the Indre, the Creuse, the Anglin and the Vienne. A great part of the area is reclaimed land and about 80 per cent of the total area is cultivated. Barley, wheat and grapes are the principal crops. Stock-raising also is important. Cloths, hosiery, paper, porcelain and farm implements are manufactured. Iron is mined in small quantities. The capital is Châteauroux. Pop. 287,673.

INDRE, France, a river which rises in the department of Creuse, flows in a northwesterly direction through Indre and Indre-et-Loire and debouches into the Loire 15 miles below the city of Tours. Its total length is 136 miles, for 40 of which it is navigable for light-draught vessels. La Châtre, Châteauroux and Loches are the principal towns along its banks.

INDRE-ET-LOIRE, France, an inland department of the republic, formed out of the ancient provinces of Touraine, Pitou and Anjou, northwest of Indre (q.v.). It has an area of 2,377 square miles of which about 1,300 are arable. It is traversed or watered by the Loire, Cher, Indre and Vienne, all navigable for vessels of light draught. Levees protect the land from the overflow of the Loire. The southern part is mostly waste land. Wine is the chief industry. Iron, powder, textiles, leather and silk are manufactured. There are three arrondissements—Tours, Chimon and Loches. Tours is the capital. Pop. 341,205.

INDUCTION, *in logic,* that method of reasoning which establishes general laws or

specific predictions of future, present or past facts on the basis of individual experiences. It is the type of argument by which, let us say, the law of universal gravitation is demonstrated on the basis of observations as to the mutual attraction of certain given bodies, or by which an insurance company is able to determine a safe price for future policies on the basis of past statistical tables, or by which the geologist may describe the history of a certain drainage system through his knowledge of the present status of the system and of the modifications taking place in the drainage systems of the present time. Induction differs from deduction not only in that it starts from particular facts rather than general laws, but also in that the propositions derived by an induction (not covering every single case of the law it sets out to establish) never even appear to have that apodictic certainty which we naturally attribute to the results of correct deduction from indisputable premises. An induced conclusion is only *probably* true; furthermore, if it is at all precise in its terms, it is in general only *approximately* true. The probable correctness of the successive digits of a decimal fraction obtained by inductive reasoning falls off with amazing rapidity. A number, the first nine digits of which are all but absolutely certain, may well have a highly probable 10th digit, a likely 11th and an absolutely worthless 12th.

Induction, then, is the probable and approximate demonstration of laws or predictions on the basis of concrete experiences. It is *not* what it has been considered by Hume and the other 18th century British empiricists: the formation of general ideas—i.e., universals—from mere particulars. In the first place, a universal is not a universal law, nor is a fact a particular. But furthermore, we do not form the notion of red by looking at this red thing and that, and abstracting from them their common quality, nor by associating with the image of one red thing all our past experiences of red objects. There are an endless number of attributes possessed by a group of things, and even exclusively possessed by this group. Redness can only be one of these. When we see the group we recognize redness either as the color quality they possess in common or as their simplest common attribute, or because redness is the property that most attracts our attention. In all these cases we must have a concomitant or antecedent consciousness of a universal—of color, simplicity or redness itself. The process described by the British empiricists simply does not exist, and every formation of a general notion from experience involves an existing awareness of general notions. That is, notwithstanding the contrary opinion of the nominalists, the general notions of qualities and relations which enter into the presentment of inductive laws are not mere mosaics of particular sense data. In a like manner, the inductive laws themselves are not mere mosaics of particular facts. A very common expression among inductive logicians, due to J. S. Mill, is "the uniformity of nature." We are justified in proceeding from this fact and that fact and the other fact to the general law subsuming them all because nature is uniform. This principle of the uniformity of nature has two very different meanings. It may be little more than a tautology or it may be the cardinal law of natural science—or all science, for the matter of that. If the uniformity of nature means simply what it says, it means merely that two occurrences can never agree in all but one aspect and disagree in that one. Now, as even an approximately complete inventory of the aspects of an occurrence is never at our disposal, and since moreover the temporal and spatial position of an occurrence must be considered in enumerating its aspects, this law tells us, for all practical purposes, absolutely nothing. Nature might be perfectly uniform, even though the jumping of a flea should determine the motions of the planets; the establishment of astronomical laws, however, would be a somewhat difficult pursuit.

The uniformity of nature, as the scientist understands it, is much more than this. It could be called more appropriately the continuity of nature. Perhaps it is best to consider it in the form which it assumes in the Newtonian physics. In the Newtonian physics, the world is completely described when the density of the matter occupying each point of space at some instant is known, together with the magnitude and direction of its velocity. The investigations of physics consist then in determining the actual form of the relation between quantities representing time, space, local density, direction and magnitude of velocity. In the attempts to discover the function which the time forms of the remaining seven variables, one assumption is always made—that this function is in general (i.e., in the language of the mathematician except at a set of points of zero measure) what the mathematicians term *analytic.* One consequence of this is that the function is continuous—i.e., by making sufficiently small changes in the seven variables, we may make the difference of time that results smaller than any assigned quantity, and keep it smaller. Furthermore, if we take a large number of experimental determinations of the time and the other seven variables, it is possible to construct a unique function of the seven variables which will represent the time at each of these points and which, by simply increasing the number of experiments, may be made to differ from the function representing the actual course of phenomena by less than any assigned quantity over any desired period of time. Two things follow: first, sufficiently slight errors in the observations only mean slight errors in the law covering the observations; secondly, by increasing the number of observations, it is possible to render the maximum error in the law formulated to cover them less than any given value. These facts assure us that by taking a sufficient number of observations, and by exercising a sufficient amount of care in each observation, we may approximate as near to the truth as we desire. That the amount of labor in obtaining a reasonable approximation is not beyond all human powers is an article of faith which may be said to constitute a part of what we mean by the law of the uniformity of nature. Other important elements have to do with the spatial distribution of phenomena. Not only the very small, but also the very remote, is inaccessible to observation and measurement. The existence of a scientific physics depends on our ability to neglect the phenomena at sufficiently great astronomical distances. Similar propositions assuring us of the negligibility of that

which is sufficiently difficult to observe are basal for other aspects of physical theory.

The law of the uniformity of nature in physics then involves something like the following aggregate of statements: (1) There is a single equation subsisting between the time, the density of matter at every point of space at the time, and the direction and magnitude of velocity at that point. (2) This equation is such that each of the unknowns involved is in general an analytic function of all the rest — that is, among other things, that sufficiently small changes in the other unknowns produce only slight changes therein. (3) The error as to the occurrences near us made by considering only those physical phenomena within a sphere of finite radius with ourselves at the centre ultimately decreases very fast as the radius of the sphere increases.

If these statements are taken together with rough estimates of the order of magnitude of the change that the changes of some of the physical phenomena mentioned in 2 and 3 entail in others, we have the barest outline of the law of the uniformity of nature as it is found in physics. This law is very far from being a tautology — it is not even obvious. Furthermore, it is specifically a law of physics, and has only been established since the time of Newton by inductive physical researches. Other disciplines, such as psychology, have related but different laws of uniformity. They all involve statements of the continuity of certain concrete phenomena. It appears, then, that induction demands antecedent universal propositions that are not identically true — *ex puris particularibus nil concluditur* is not confined to deduction. These synthetic propositions, a priori at least in part, go back and back until in the last analysis they are due simply to a general consonance between the human mind and the facts of nature. This consonance, which consists largely in a preference for continuity both on the part of the mind and of nature, is continually rendered more perfect by the attrition of our imaginings in the places where they disagree with our observations. The history of science consists in a gradual remodeling of each theory in the points where it is wrong, in a mathematical treatment of the errors of the last mathematical treatment. It will be seen that in the theory here developed the distinction between induction and deduction is not absolute, but is rather one of degree and attitude. The stages of an inductive research are: (1) the imagination of a theory to fit the facts; (2) the deduction of the consequences of the theory; (3) the verification of these consequences and the observation of their errors; (4) the imagination of a theory to account for the errors of the original theory or the formulation of a new theory avoiding these errors. The process runs through a regular never-ending cycle. Stages (1) and (2) are identically those of the mathematician in his purely deductive reasoning. Stages (3) and (4) may be paralleled in a mathematical research where the object is the formation of an algorithm which will subserve an especial end. The only difference is that the verification which the mathematician makes is complete, that of the physicist incomplete.

The importance given to continuity in this article may be expressed by saying that the chief inductive method of the scientist is what Mill calls the method of concomitant variations. Mill's canon for this method is: "Whatever phenomenon varies in any manner wherever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation."

It will be noted that Mill gives a causal interpretation to the method. It has always been the custom of the philosopher, and almost never the custom of the scientist, to interpret the laws of nature under the aspect of cause. A law of nature is simply a more or less precise formula to which occurrences conform. Sometimes, and only sometimes, the correlated phenomena will have a temporal order, and we may talk of antecedents and consequents. In such a case the antecedents may be called causes and the consequents effects. This implies no obscure effective force emanating from the cause and proceeding to the effect — Hume demolished that notion long ago. A causal interpretation of the universe, then, consists merely in selecting one especial type of inductive correlation and elevating it to the type of all induction whatever.

Causal language is particularly adapted to vague, ill-defined phenomena, about which we can assert little but their presence or absence. Accordingly Mill's remaining canons of induction deal with such phenomena. The method of agreement argues a causal relation between A and B when two trains of circumstances are known which begin in A, and have nothing else in common except their termination in B. The method of difference concludes that A causes B if a train of events is known which contains A and ends in B, while a train of events precisely similar except in that it does not contain A likewise fails to contain B. The joint method of agreement and difference is what its name would imply. The method of residues is that in which the unexplained parts of a nexus of events are linked up with one another. Not one of these methods is without grave dangers except in the hands of the scientist with a concrete knowledge of the field where he applies it. The artificial division or antecedent and consequent alike into a jig-saw puzzle of yes and no occurrences is vicious in the extreme.

Induction has been a method of human reasoning from time immemorial, and has especially characterized those centuries since Francis Bacon. Aristotle, who was the first to recognize induction as a scientific method, gave a very scant account of induction other than that by a complete enumeration of instances. Bacon followed him in this excessive restriction of inductive reasoning. The beginning of the 17th century marks a period when the progress of science had forced a consciousness of the inadequacy of the Aristotelian logic upon the world of learning. The accepted theory of deductive reasoning began to be supplemented in practice by a methodology, but no approximately adequate treatment of this methodology was developed until the middle of the 19th century. In 1840 Whewell (q.v.) published a work in which for the first time due credit was given to the function of imagining and speculation in inductive reasoning. Soon afterward Mill published his 'Logic,' in which he formulated the five methods of inductive research that have already been mentioned, and expressed the theory, also mentioned above, that every induction in a syllogism with the uniformity of the nature as its major premise. Since the time of Mill the growth of inductive logic and methodology has been extremely rapid. (See LAW IN SCIENCE AND PHILOSOPHY; LOGIC; MILL, JOHN STUART). Consult Aristotle, 'Organon'; Bacon, F., 'Novum Organum'; Joseph, H. W. B., 'Introduction to Logic' (Oxford 1906); Mill, J. S., 'System of Logic' (London 1843); Russell, B. A. W., 'Our Knowledge of the External World' (Chicago 1914); Welton, 'Manual of Logic' (Pt. 11, London 1896); Whewell, W., 'Philosophy of the Inductive Sciences' (London 1840).

NORBERT WIENER,
Editorial Staff of The Americana.

INDUCTION, *in physical science,* the process by which a body having electrical or magnetic properties calls forth similar properties in a neighboring body without direct contact; in short, electrical influence. It is a familiar fact that an electrified or magnetized body causes electrical or magnetic disturbances in other bodies in its vicinity, when it is not in direct and visible connection with them, and this, in particular, illustrates the process known as induction. The word induction as employed by physicists occurs in combination with a number of other words, and involves, as well some other peculiar terminology, at which it may be not inadmissible to glance. Thus:

Statical or electrostatic induction is applied to the production of an electrical charge upon a body by the influence of another body which is charged with statical electricity. It can be shown by experiment that the inductive influence is transmitted through a non-conducting medium which may be considered as in a state of strain or tension. It is found, further, that the character of the medium determines the amount of induced electricity. The power of a non-conducting substance to transmit an influence of this kind, as compared with that of dry air, is known as its specific inductive capacity or dielectric capacity.

The principle of statical induction is involved in the electrophorus, in the Holtz and also in other influence or induction apparatus; and in the condenser, as in a Leyden jar, voltaic or electrodynamic induction, it is the production of an electric current, or rather an electric motive force, by the influence of an electric current. This latter is called self-induction when upon its own circuit; but mutual-induction, if it is the induction of a current upon another circuit. By current is here understood a definite quantity of electricity per second. When the current is induced by the action of a magnet, or when a magnetic condition is induced by an electric current, the result is alluded to as an example of electro-magnetic induction. Magnetic-induction is the production of magnetic properties in a magnetic substance, as in a soft-iron bar, by a near-by magnet, or by an electric current. Mutual induction is the reaction of two electric currents upon each other, a phenomenon due to the variations in distance between them. Peristaltic induction is applied by Thomson and others to mutual electrostatic induction between the wires of a multiple cable. Flow of induction across an element of surface in magnetism is the product of the surface of the element by the perpendicular component of induction.

Faraday disclosed the existence of the power and action of electric currents in neighboring conducting circuits to the world. His researches on induction, named by him "voltaic-electric induction," were published in the 'Philosophical Transactions' during 1831–32. Joseph Henry, in 1832, observed that when contact was broken in a long galvanic circuit, a bright spark occurred, which did not appear, when the circuit was short. This was shown by Faraday, in 1834, to be due to the extra current induced by the various parts of the circuit in each other. Bachhoffner, and also Sturgeon, in 1837, demonstrated that superior action, in induction apparatus, of a bundle of iron wires to that of a solid bar of iron. Henry, in 1841, studied the inductive action of induced currents of different orders. De la Rive designed, in 1843, an electro-chemical condenser, consisting of a primary coil, which, by means of an extra current, could enable a single galvanic cell to decompose water. The same decomposition, however, had been effected by White in 1840. Ruhmkorff constructed, in 1850 or 1851, the first so-named "induction-coil," the excellence of which was owing chiefly to the proper insulation of the secondary coil. Fizeau, in 1852, increased greatly the power of the coil by providing it with a condenser. This electrical instrument consists of two coils of wire wound one over the other upon a core consisting of bundles of iron wires. One of its circuits is called the primary circuit and the other the secondary circuit. These coils are employed for physiological purposes and also in connection with the telephone. But it is in connection with high-frequency electric currents for Röntgen ray work and wireless telegraphy that one finds the employment of the induction coil most often used at present. Of late years, coils of great power have been constructed, rivaling, if not exceeding, the most powerful electric machines in length and power of spark.

In considering induction, mention may be made to the interesting theory of Ampere. 'Ampere's theory' is applied to an electrodynamic theory proposed by Andre Marie Ampere. According to it, every molecule of a magnetic substance is supposed to be traversed by a closed electric current. Before magnetization the combined effect of these currents is zero. But by the magnetizing process they are supposed to be brought more or less fully into a parallel position. Then their resultant effect is said to be equivalent to a series of parallel currents traversing the exterior surface of the magnet in a plane perpendicular to its axis, and a certain definite direction, which, when the south pole is turned toward the observer, is that of the hands of a watch. These hypothetical currents are called Amperian currents. This theory is based upon the close analogy between a solenoid traversed by an electric current and a magnet. Ampere thus conceived that the magnetic action of the earth is the result of currents circulating within it, or at its surface, from east to west, in planes parallel to the magnetic equator.

The ultimate mechanism of induction is still somewhat obscure, but something has been learned of its general nature. In the early days of physical science it was believed that bodies

can act upon one another even across spaces that are absolutely void, and at the present time it is sometimes convenient to assume them to act in this manner, in forming mathematical equations for the treatment of physical problems. It is no longer believed, however, that this is what actually happens in nature; the phenomena of electric and magnetic induction being now attributed to motions or stresses in the ether which transmits light. (See ETHER). Newton was of the opinion that induction is an ether-phenomenon, and in the first half of the 19th century Faraday may be said to have established the ether hypothesis upon a substantial experimental foundation. In later years Maxwell developed Faraday's conceptions mathematically, and added much more evidence that was partly theoretical and partly experimental; so that at the present time there are few or no physicists who doubt that induction is a manifestation of some form of activity in the light-bearing ether. Opinion is still divided, however, as to the precise nature of this activity. In fact, we cannot hope to gain any very precise information on this point until much more is known about the constitution of the ether itself.

The charging of a condenser is a phenomenon in electrostatic induction. If the condenser consists of two parallel plates (for example), of a given size and set at a constant distance from each other, and we charge it to a given potential, the quantity of electricity that must be put into it in order to charge it in this manner depends to a considerable extent upon the nature of the dielectric (or insulating material) which separates the plates. If the charge that is required when air is the dielectric is taken as unity, then with plate glass as a dielectric the charge will have to be 8.45 (according to Hopkinson), in order to bring the potential of the condenser up to the same value as before. If the space between the plates is filled with common turpentine, a charge 2.23 times as great as that required with air as the dielectric must be communicated to the condenser. It is evident, from these facts, and from others of the same nature, that electric induction depends, to a large extent at any rate, upon the nature of the medium which separates an electrified body from the other bodies upon which the inductive influence is felt. The constants that are given above are known as the «specific inductive capacities»of the dielectrics to which they refer.

Electrodynamic induction is the basis of practically all of the electrical machinery that has been found serviceable to man. The fundamental fact of electrodynamic induction may be stated as follows: If a closed electrical circuit, such as might be formed by joining the two ends of a copper wire, is placed in a magnetic field, then no current will be produced so long as the circuit is everywhere stationary, and the strength of the magnetic field remains everywhere invariable. If the intensity of the magnetic field is increased, a current of electricity will flow around the circuit while the intensity of the magnetism is changing, the intensity of the current being proportional to the rapidity with which the intensity of the magnetism varies. As soon as the magnetism again becomes constant, the current in the circuit ceases. If the intensity of the magnetic field be diminished instead of increased, a current will also be produced in the closed circuit, but it will be opposite in direction to that produced by increasing the magnetic field. Currents produced in this manner are called «induced currents.» Instead of varying the magnetic field while the circuit is fixed in position, we may move the circuit about in the magnetic field. If the magnetic field is everywhere uniform in all respects, and the circuit is moved so as to always remain parallel to itself, then no induced current will be produced; but if the circuit is moved from a region where the magnetism is strong to one where it is weak, or vice-versa, a current will be induced in the circuit, just as if the circuit were kept stationary and the intensity of the magnetism varied. Induced currents are also produced when, instead of being translated from one region to another, the circuit is rotated in a magnetic field, in such a way that the number of lines of magnetic force passing through it is either increased or diminished. In the induction coil the intensity of the magnetic field is varied, while the circuit in which the induced current is to be produced is kept stationary. In dynamos, on the other hand, the magnetic field is maintained sensibly constant, while the circuit in which the induced current is to be produced is rotated or otherwise moved about.

A current moving in a closed circuit produces a magnetic field in the space above it, and this magnetic field, when it varies on account of the variation of the current that produces it, causes the production of induced currents in any closed circuit that may happen to be near. Let us conceive two closed circuits, A and B, to be situated near each other, and let there be a current produced by any means in the circuit A. So long as the current in A is constant, no current will be produced in B; but if the current in A is variable, an induced current will be observed in B, whose intensity depends upon the rate at which the current in A is varying, upon the resistance of the circuit B and also upon a certain numerical factor, whose value depends upon the sizes and shapes of the two circuits, upon their positions with respect to each other, and upon the nature of the medium (air, oil and whatever it may be) in which they are placed.

If a pair of circuits, A and B, are near each other, and A is carrying a constant current of intensity C_1, while B is carrying a constant current of intensity C_2, then the displacement of either circuit, relatively to the other, would cause induced currents to flow in both; and hence (in general) neither circuit can be moved without the energy of the system being affected. The difference between the energy of a pair of coils that are near together, and the energy of a similar pair of coils that are conveying identically the same currents but are infinitely remote from each other, is equal to MC_1C_2, where M is a numerical factor whose value depends upon the sizes and shapes of the two circuits, upon their relative positions and upon the medium in which they are placed. The factor M is called the «coefficient of mutual induction» of the pair of circuits.

The various parts of a single circuit act upon one another inductively, just as separate circuits do; and a circuit that is wound upon a spool, or otherwise coiled so that its parts come near together, possesses greater energy than the same circuit would have, if it was not so coiled.

This fact is expressed by saying that every circuit has a certain amount of «self-induction.» The energy that a circuit possesses in virtue of its self-induction is proportional to the square of the current that it is carrying, and to a certain numerical constant called the «coefficient of self-induction,» whose value depends upon the size and shape of the circuit, and upon the medium in which it is placed. Like the coefficient of mutual induction of a pair of circuits, the coefficient of self-induction of a single circuit can be computed, for certain simple cases, by methods given by Maxwell, in his 'Treatise on Electricity and Magnetism'; but in the general case the computation is exceedingly difficult, and altogether impracticable; so that the values of these coefficients for given circuits are usually determined experimentally, except when a very rough estimate will serve.

The general subject of induction is essentially mathematical in its character, and cannot be properly explained nor understood without the use of the calculus. Consult Nipher, 'Electricity and Magnetism'; Maxwell, 'Treatise on Electricity and Magnetism.' See also the articles ELECTRICITY and MAGNETISM, in this encyclopædia.

INDUCTION, Mathematical. Despite the age-long tyranny exercised by the Aristotelian logic — a tyranny having, at least in the domain of science, scarcely a match except in the case of Euclid's elements — the forms of thought, those diagrammatic representations of the orderliness of the reasoning processes, sustain to-day perhaps even greater interest than ever before (see SYMBOLIC LOGIC). The mathematician's interest in these forms is twofold, attaching to them both as norms for testing the validity of arguments and as constituting exceedingly subtle matter for mathematical investigation.

Of all argument forms, there is one which, viewed as the figure of the way in which the mind gains certainty that a specified property belonging but not immediately by definition to each element of a denumerable (see ASSEMBLAGE THEORY) assemblage of elements does so belong, enjoys the distinction of being at once perhaps the most fascinating, and, in its mathematical bearings, doubtless the most important, single form in modern logic. This form is that variously known as reasoning by recurrence, induction by connection (De Morgan), mathematical induction, complete induction, and Fermatian induction — so called by C. S. Peirce, according to whom this mode of proof was first employed by Fermat. Whether or not such priority is thus properly ascribed, it is certain that the argument form in question is unknown to the Aristotelian system, for this system allows apodictic certainty in case of deduction only, while it is the distinguishing mark of mathematical induction that it yields such certainty by the reverse process, a movement from the particular to the general, from the *finite* to the *infinite*. See ASSEMBLAGES, THEORY OF.

Of the various designations of this mode of argument, «mathematical induction» is undoubtedly the most appropriate, for, though one may not be able to agree with Poincaré (see *Bibliography* below) that the mode in question is *characteristic* of mathematics, it is peculiar to that science, being indeed, as he has called it, «mathematical reasoning par excellence.»

The nature of mathematical induction as it is ordinarily understood may be made clear by an example. Perhaps the simplest application of the method is found in the proof of the theorem:

$$(\alpha)\quad 1+2+3+\ldots\ldots+n=\tfrac{1}{2}n(n+1)$$

where n denotes any positive integer whatever. Suppose it ascertained by observation or otherwise that

$$(1)\quad 1+2=\tfrac{1}{2}2(2+1),$$
$$(2)\quad 1+2+3=\tfrac{1}{2}3(3+1).$$

Facts (1) and (2) justify the *suspicion* that (α) may be a fact. The proof by mathematical induction that (α) is indeed true runs as follows: It is *assumed* that (α) is true for some definite but unspecified integer n. Then by adding $n+1$ to each member of the assumed equation, n having the same meaning as in the assumption, one finds that

$$(\beta)\quad 1+2+3+\ldots\ldots+n+\overline{n+1}$$
$$=\tfrac{1}{2}(n+1)\,(n+2).$$

So it is seen that, if (α) *be* true for *some* integer n, it *is* true also for the *next* greater integer $n+1$. But by (2), (α) is true when n is 3; it is, therefore, true for $3+1$, or 4; therefore, for $4+1$, or 5. The argument is then usually closed by saying «and so on, hence (α) is true for any integer whatever,» or by an equivalent speech. The reader will recall that the binomial theorem, the Newtonian expansion of $(a+b)^n$, where n is any positive integer, is justified in essentially the foregoing manner. Numerous other examples of propositions similarly established may be found in the better recent textbooks of algebra.

The nature and the rôle of the foregoing *et cetera*, «and so on,» demand consideration. Without it, the argument as stated seems obviously incomplete. But how is the *et cetera* to be logically justified? By reference to some axiom or principle of thought? If so, what? Or can the phrase be in some way dispensed with without damage to the argument?

Before attempting to answer them it may be well to show the inevitableness of the questions by a further analysis. Suppose it established, in regard to some property p (where, for example, p might signify the validity of the binomial theorem for some integral exponent): (1) that p belongs to the integer 1, that is, referring again to the mentioned example, the theorem is valid for the exponent 1; (2) that, *if* p belong to an integer n, it belongs to $n+1$. Propositions (1) and (2) furnish the means of generating, one after another, a sequence of syllogisms by which one proves first that p belongs to 2, then to 3, then to 4, and so on. Note that in order to ascertain by this analytic (syllogistic) method whether p belongs to a specified integer m, it is necessary to determine in advance the same question for each of the integers 2, 3, ..., $m-1$, in the order as written, a process requiring a number of syllogisms which is greater the greater the number m. Accordingly *this* method, of successive deductions, is not available for determining whether p belongs to each in the (infinite) *totality* of integers. Equally powerless to that end is experience (including observa-

tion), for this can take account of the individuals of a finite assemblage of objects at most. Either analysis or experience may avail if a sequence be finite, but if it be infinite both must fail. Not less vain is it to invoke finally the aid of induction as the term is understood and employed in the physical sciences, for this latter, resting upon a purely assumed order in the external universe, is confessedly *inductio imperfecta*, and, being such, can yield approximate certainty only.

Nevertheless, despite the inadequacy of the means mentioned, as soon as hypotheses (1) and (2) are admitted and the indicated sequence of deductions is *begun*, "the judgment imposes itself upon us with irresistible evidence" that p is a property of *all* the integers. Why? That is, how justify the "and so on"? It appears to be clear that the answer must be the adduction or invocation of an additional presupposition of formal thought, a presupposition whose formulation shall mark a conscious extension of the domain of logic by affirming as axiomatic that apodictic certainty can and does transcend every limited sequence of deductions or observations. Such presupposition, which may be called the axiom of infinity, is stated by Poincaré, in answer to the foregoing question, "why," as follows: "It is the affirmation of the power of the mind which knows it is capable of conceiving the indefinite repetition of a same act as soon as this act is found to be once possible." The act or operation, which cannot indeed be indefinitely repeated, but which by the axiom can be conceived as so repeated, is, in the present case, the construction of the syllogisms of the sequence above mentioned.

The *et cetera* in question is capable of justification without appealing, apparently at least, to the axiom of infinity, namely, by use of the so-called indirect method of proof, the method known as *reductio ad absurdum*. Thus let it be supposed that the argument sought to be indefinitely extended by means of the phrase "and so on" does not admit of indefinite extension along the ordered sequence of integers. There will, then, be a first integer, say $m+1$, for which the property p fails. As, by hypothesis, $m+1$ is the first integer for which p fails, p belongs to the preceding integer m; but since p belongs to m, it also belongs, by (2), to $m+1$. Hence the supposition that the argument does not admit of indefinite extension is false; and the conclusion is obvious. This procedure is convincing, but it is plainly less a natural completion than an "unindicated" fortification of the process it supplements. It is, besides, not entirely clear that the axiom of infinity is not surreptitiously subsumed by it.

By far the most penetrating investigation of the nature of mathematical induction was made originally by Richard Dedekind. (See *Bibliography* below). His procedure and result are, in brief, as follows: Let S denote a system of elements (things of any kind) such that there is a scheme of law ϕ of depiction by which S may be depicted upon itself, that is, a scheme by which each element e of S may be thought as corresponding to one and but one element e' of S and so that no two elements of S shall be thought as corresponding to a same element of S. The correspondent e' of e is called the picture or image of e. Every part of S (including S itself as a special case) thus depicted upon itself is named *chain under* ϕ. Denote by A an arbitrary part of S and by A_0 the assemblage of all the elements common to all the chains (in S) that contain A. It is obvious that, S and ϕ being given, there is one and but one A_0 for a given part A of S. A_0, which is easily seen to be itself a chain, is described as the *chain of A under* ϕ. Now let Σ denote an assemblage of elements. Dedekind proves the following

THEOREM.—*In order to prove that A_0 is part of Σ it is sufficient to prove:* (1) *that A is part of Σ; and* (2) *that, if an element A_0 belong to Σ, the image of that element belongs to Σ.*

Dedekind's proof, simplified, runs thus: Let $A_0 = A_1 + A_2$ where A_1 denotes the assemblage of all those elements of A_0 that belong to Σ. By (2), A_1 is a chain, and, by (1), contains A. Hence, by definition of A_0, A_2 has no element, whence $A_0 \equiv A_1$. Such is the beautiful and marvelously fundamental theorem which its author characterizes, perhaps a little extravagantly, as "the scientific basis" of mathematical induction. It is at any rate *a* basis, and by virtue of it, as shown below, proof by mathematical induction need have no recourse to an *et cetera* consisting of an endless sequence of syllogisms.

It will be instructive to apply Dedekind's theorem to the *completion* of the proof by mathematical induction of the binomial theorem.

$$(\alpha)\quad (a+b)^n = a^n + na^{n-1}b + \dots\dots\dots$$

for positive integral exponents. Let it be granted that

$$(\beta)\quad (a+b)^1 = a+b,$$

and supposed it established in the usual way that (γ), if (α) be valid for some integer, as $n-1$, then it is so for the next, n. Denote by S the sequence of integers,

$$S \equiv 1, 2, 3, \dots\dots, n-1, n, \dots\dots,$$

by ϕ the scheme by which each number in S except 1 is the image of its predecessor, and let A be 1. Then A_0 is S identically. Let Σ denote the assemblage of positive integers for which (α) is valid. The reader will now observe that Dedekind's theorem enables one to prove by a *single* stroke, so to speak, that (α) is valid for all positive integers. For, by (β), (α) is valid for 1, that is, A is part of Σ and (1) is satisfied; and, as A_0, or 1_0, is S, it follows from ( ) that (2) is satisfied; γ hence S is part of Σ.

With the modern increasing interest in the philosophy of mathematics, mathematical induction has steadily gained in interest and acknowledged importance. Certain questions respecting its presuppositions and field await definite answers. It is agreed that every argument by mathematical induction is a mathematical argument, no matter what the subject-matter, but there is difference of opinion as to whether every mathematical argument is mathematical induction either in terms or in disguise. Were this converse true, mathematics (see MATHEMATICS) would be definable in terms of this mode of ratiocination. This and kindred questions are considered in the works cited below.

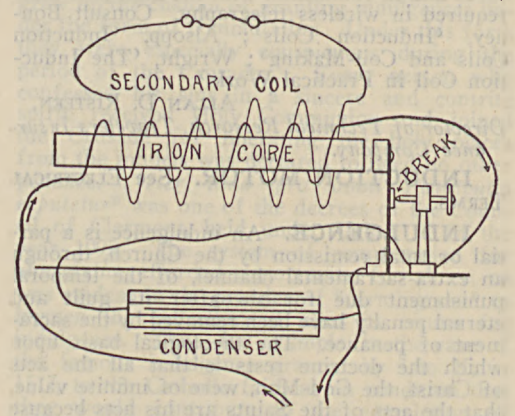
INDUCTION BALANCE, in physics, an apparatus designed for measuring and indicating the electrical conductivity of metals. It is based upon the principle of induction. The mere proximity of a metal, especially a metal that is a good conductor, will induce or draw magnetization as electrification from a charged wire, battery, etc. An induced current is always opposite in positivity to the near side of the charged source of current. In its most familiar form it consists essentially of four coils of fine wire, an electric battery, a circuit breaker and a telephone. Let the coils be designated, respectively, by the letters A, B, C and D; A being similar to B in all respects, and C being likewise similar to D. Coils A and B are placed in circuit with the battery, and coils C and D are placed in circuit with the telephone. The coils are disposed in pairs, A being placed near C, and B near D. If the current through A and B is rapidly interrupted, an induced current will, in general, flow through C and D, at each make and break; its presence being indicated by the sounds that it produces in the telephone that is in circuit with C and D. It is possible, however, to dispose the coils and their connections so that the current that A induces in C shall be sensibly equal and opposite to that which B induces in D. When the balance is perfect no sound will be heard in the telephone. If a piece of metal be now brought near the coil A, the intermittent current in A will induce currents in the mass of the piece of metal, and these, in turn, will act upon the coil C, producing induced currents in this coil which are not compensated by similar currents in D. The loss of balance will be at once indicated by the recurrence of sounds in the telephone; and in this way the metal fragment will betray its presence. The induction balance has been used successfully for locating bullets in the human body. The intensity of the sounds produced in the telephone depends not only upon the size and position of the disturbing piece of metal, but also upon its specific electrical resistance; and hence the balance may be used to compare the specific resistance of metals. When an induction balance is arranged for making measurements of electrical resistance it is usually termed an induction bridge.

INDUCTION COIL, one of the early electrical instruments, that simply illustrates the principle of induction, consisting of an iron core about which two wires are differently coiled: now used mainly for study, and in connection with high frequency currents, radiography and X-ray investigations. (See INDUCTION). The essential features of the instrument are represented, diagrammatically, in the accompanying cut. A soft iron core is surrounded by two coils of wire, the finer one outside of the other. The outer coil is the one in which the high tension induced currents are produced; it is called the "secondary coil," and is not in direct electrical connection with any other part of the instrument. The inner coil, which is called the primary coil, is of coarse wire, wound close to the iron core, and is connected to a battery, so that when the current from the battery is flowing the primary coil causes the iron core to become magnetised. As is explained in the article INDUCTION, no current is generated in the secondary coil, so long as the magnetism of the iron core remains constant; but whenever the magnetism of the core increases or diminishes, a current is produced in the secondary. A device called a "break" or "interrupter" is therefore provided, so that the magnetism of the iron core may be rapidly established and destroyed. The commonest form of interrupter is that indicated in the cut, which does not call for special explanation, since it is used in electric bells and other simple forms of electrical apparatus. The Wehnelt electrolytic interrupter is greatly in favor among physicists, however, and is now often used in connection with induction coils,



especially when they are to be run with the commercial current used for incandescent lighting, where the potential difference that is used is something over 100 volts. In the Wehnelt interrupter the primary coil on the iron core is made of a few turns of relatively thick copper wire, its purpose being solely to effect the magnetisation of the core; but the secondary coil, in which the induced currents are generated, is made of fine wire, and in order to multiply the inductive effect as far as possible, the secondary is made of great length, often containing many miles of wire. In the celebrated Spottiswoode coil the secondary contained no less than 280 miles of wire. The primary coil, being wound directly upon a soft iron core, commonly has a very considerable amount of self-induction, so that when the circuit is broken by the interrupter the current does not suddenly cease, but continues to flow across the interval at the break for an appreciable fraction of a second, as is readily seen by the strong sparking that occurs at the moment of interruption. In order to reduce the sparking as far as possible, a condenser of suitable capacity is provided, so that when the break is made in the circuit, the "after-current" due to the self-induction of the primary can

discharge into the condenser, instead of passing across the break in the circuit and causing a spark. The condenser causes the interruption of the current in the primary coil to be much more sudden, and it materially increases the potential that is developed in the secondary coil, since this is proportional to the rate of variation of the magnetism of the core, and is much greater when the magnetism falls off abruptly than when it persists for an appreciable fraction of a second after the break has been made.

The induction coil was brought into something like its present form by Ruhmkorff, and is frequently known, in consequence, by his name. Improvements in the winding of the secondary coil were introduced by Ritchie of Boston about 1857. Ritchie's most important improvement consisted in disposing the secondary wire in sections, which were so related to one another that the risk of internal disruptive discharge through the coil itself might be reduced to a minimum. Induction coils are very generally used in studying the discharge of electricity through gases, for exciting X-ray tubes and in connection with the high potentials required in wireless telegraphy. Consult Bonney, 'Induction Coils'; Alsopp, 'Induction Coils and Coil-Making'; Wright, 'The Induction Coil in Practical Work.'

INDUCTION MOTOR. See ELECTRICAL TERMS.

INDULGENCE. An indulgence is a partial or total remission by the Church, through an extra-sacramental channel, of the temporal punishment due for sin after its guilt and eternal penalty have been removed by the sacrament of penance. The theological basis upon which the doctrine rests is that all the acts of Christ, the God-Man, were of infinite value, that the acts of the Saints are his acts because vivified by divine grace, and from this treasury of divine, supereminent merit the Church is able, so to speak, to pay the debt of temporal punishment for the repentant sinner.

Certain cardinal principles of Catholic life are requisite to obtain a correct idea of the Catholic doctrine of indulgences. Growth and adaptation have characterized the Christian organism from the Apostolic Council of Jerusalem to the Œcumenical Council of the Vatican. The development of doctrine, upon which such explicit emphasis was laid by the late Cardinal Newman, is of prime significance for the student who would institute a comparison between the teaching and practice of the Church in the matter of indulgences at the present day and during apostolic times. We may observe in passing that the principle of doctrinal development is in perfect harmony with the scientific spirit of the present age. Growth and adaptation are now believed to be distinguishing features of every living and progressive organism. We should not, therefore, expect to find the Catholic system of indulgences, in all its complex details, flourishing in the primitive Church. In harmony with the law of development, essential to every organization among men, we believe that the Church's "proud boast of *semper eadem*" is not defeated by calling attention to the richness, variety and flexibility of the outer forms of its polity and liturgy, or to the varying emphasis given to special dogmas in the course of its history, in response to the needs of particular eras. Unity in diversity is the Church's most appropriate motto. The doctrine and practice of indulgences, therefore, which obtain throughout the Catholic world at the present time must be sought for only in germ in Sacred Scripture and in the practice of the primitive Church, just as the bole, the branches and the foliage of an oak tree, "the monarch of the forest," existed potentially in the acorn from which it sprung.

Indulgences being the remission of the temporal punishment due to sin, the interpretation of the true character should start from the Christian idea of the nature and purpose of punishment. It is therefore strange that writers of all schools of opinion concerning indulgences should fail to correlate the two concepts. At the present day the conviction prevails almost universally among non-Catholic students of penology that punishment is exclusively disciplinary and correctional. No theory could be more alien to the spirit of the entire Old Testament or to the mind of the early Christian Fathers. The inflexible and rigorous justice of God making death the wages of sin appears in almost every page of the history of his covenant with Israel. The New Testament, founded on the atonement by Christ, only mitigates this view by impressing on the minds of men the possibility of vicarious satisfaction for their transgressions. But although Christ's atoning and vicarious sacrifice was all-sufficient in itself, or objectively considered, to satisfy the offended justice of his Heavenly Father, nevertheless the Christian economy of redemption demands each individual's co-operation at every stage in order to appropriate Christ's merits and make them subjective to himself. The opposite view (that is, the belief), that the creature has no active part in his sanctification and salvation, inclines toward Pantheism, robs good works and the Christian sacraments of genuine value, and differentiates the Lutheran from the Catholic position. According to Catholic teaching the guilt of sin is cleansed from the soul by the application of the merits of the precious blood of Christ through the instrumentality of the Sacraments, whose efficacy, in the case of adults, depends on the subjective disposition of the recipient. The eternal punishment due to sin disappears with the guilt to which it is annexed. But, besides having these supernatural and eternal relations and consequences, sin viewed even within the circumscribed limits of man's natural life on earth is an act of treason against God in His own kingdom involving forfeiture of all rights to life and all the good things with which God's providence has so bountifully enriched it. This temporal consequence of sin calls for a temporal reparation. The canonical penalties therefore imposed on the Church during the first centuries were intended to pay this temporal debt to the Divine justice, and were not merely disciplinary or correctional; and the sinner, in submitting to them, or in seeking mitigation from them through the intercession of the martyrs, recognized the necessity of his own personal act to satisfy the justice of God, either directly or vicariously by appropriating through the charity of the Church the superabundant merits of Christ and His Saints.

An indulgence granted to the living is an act of jurisdiction, or exercise by the Church of the power of the keys conferred on it in the well-known words of the Gospel of Saint Matthew: "And I will give to thee the keys of the Kingdom of Heaven, and whatever thou shalt bind on earth, it shall be bound in Heaven, and whatever thou shalt loose on earth, it shall be loosed in Heaven." Every Church, in so far as it is a visible organization, claims in some degree a power of the keys, that is, the right to admit or exclude members — to determine fellowship. But the antithesis so emphatically expressed in the text between heaven and earth proves that the kingdom of heaven there spoken of is more comprehensive than the visible Church of Christ. It is proclaimed that the power of binding and loosing on earth bestowed upon the Apostles and their successors, is ratified in its every act by the supreme tribunal of God in the Church triumphant. In accordance with a well-known principle of Catholic exegesis, the best interpretation of a text of Sacred Scripture is furnished by the universal tradition of the Church from the age of the Apostles to the present time.

Saint Paul, in his epistles to the Corinthians, describes how he imposed punishment on the incestuous Corinthian and how he subsequently remitted it. The penalty was not merely an ecclesiastical censure of excommunication inflicted primarily for the purpose of safeguarding the flock of Christ. The Apostle expressly states that the chief motive which actuated him was anxiety for the individual salvation of the transgressor. Nor could it have been (as has been already shown) a mere disciplinary measure to impress upon the sinner the gravity of his crime or to test the sincerity of his repentance. Having no organic relation to confession, whether public or private, and no expressed or implied connection with perfect contrition, it was not a part of any conceivable Christian ordinance for the remission of the guilt and eternal punishment of sin. According to Catholic reasoning, it was therefore an exercise of the power of the keys by the Apostle to remit a temporal debt due to God for the offense; and since, according to universal Jewish and Christian belief, the Divine Justice rigorously demanded either direct or vicarious satisfaction, the Apostle could only concede that "indulgence" by appropriating to the individual sinner the superabundant merits of Christ and the Saints out of the treasury of the Church.

It will be observed that the Apostle of the Gentiles granted the first recorded indulgence in the form of an absolution. Indulgences usually took this form in the primitive Church. The early Fathers frequently refer to their being thus conceded by bishops on the presentation of a "Libellus Supplex" given to the penitent by some Christian martyr on the eve of suffering an heroic death for Christ. It is interesting to note that the present practice of never granting those favors except to persons who are in full communion with the Church, and who have received the Sacrament of Penance, was substantially insisted upon by Saint Cyprian. He demands that the martyrs should not grant "Libelli" except to persons who had abandoned their sinful career and given ample evidence of heartfelt contrition and sincere conversion. Indulgences in the first centuries of the Church having implied a diminution of the period of canonical punishment — the name by which this act of leniency was then known was *φιλανθρωπία* — (Consult Concilium Ancyra, can. 5; cf. Hefele, 'Conciliengeschichte'), such expressions as an indulgence of seven years and seven quarantines came into use. An indulgence of seven years means the condonation of as much of the temporal debt due to God for sin as canonical punishment extending over seven years would atone for. Likewise an indulgence of seven quarantines connotes a canonical punishment extending over seven Lents.

We find in the writings of Saint Augustine reference to the remission, in return for almsgiving, of temporal penalties imposed for minor ecclesiastical offenses. Thus there gradually grew up the custom of granting indulgences under the form of commutation. Under this form they were especially conspicuous during the period of the Crusades. Every person who confessed his sins in a sincere and contrite spirit, received Holy Communion and joined the Crusade for liberating the holy places from the infidels was declared to need no other penance. "*Iter illud pro omni Pœnitentia reputetur*" was one of the decrees of the Council of Clermont, held under Urban II in the year 1095. The system of commutation for almsgiving afforded opportunity for abuse, as was evident in the practice of "farming out" to laymen the collection of alms in return for indulgence. Thus, for example, in the case of the famous indulgence granted by Leo X, in 1517, to the Catholic faithful on condition that they would contribute to the completion of Saint Peter's basilica in Rome, the right of collecting the money was conferred, in the first instance, on Albert, bishop of Maintz, and then sold by him to an Augsburg banker. Circumstances like these gave occasion to the Protestant party to charge the Church with the "sale of indulgences." Cardinal Pallavicini, the celebrated Jesuit historian of the Council of Trent, does not hesitate to say that if Leo X had been surrounded by able theologians and enlightened by their counsels he would have proceeded more cautiously in dispensing indulgences. However, it should in justice be recognized that the erection of Saint Peter's in Rome, the ancient capital of the Christian world, was an enterprise of the deepest interest to every member of the faithful. Together with the incidental abuses connected with commutations, other circumstances combined to inspire disaffection for the Holy See in the minds of European rulers and their dependents; and, as in the case of every revolution fed by prolonged and deeply-rooted discontent in the minds of those who control public opinion, a spark sufficed to start the conflagration. The life of Luther recently published by the Rev. Heinrich Denifle, O.P., and the abundant controversial literature which it has called forth from the ablest Protestant historians and the-

ologians of Germany, have proved that the first Apostle of the Protestant Reformation was an epoch-maker by reason of conditions, not because he possessed in any high degree the qualities of the *Uebermensch*. Yet the nailing of his 95 thesis on the doors of the castle church of Wittenburg in protest against the indulgence granted by Leo X, and preached by Tetzel, subdelegate of Albert, bishop of Maintz, set all Europe aflame and destroyed the dogmatic unity of Catholic christendom.

Opposition to the doctrine of indulgences arose at different times, not because of their alleged novelty or repugnance to the religious sense of the Christian people, but because they did not always approve of the object for which alms were obtained by the preaching of indulgences, or because of the personal defects of those entrusted with their promulgation. It should be distinctly noted that these purposes were not always strictly religious. They were frequently philanthropic, such as the construction of bridges, the erection of hospitals, etc., and in such cases received the unqualified approval of princes and people. In order to comprehend the outburst which Luther was able to evoke against the indulgence granted by Leo X we must bear in mind, besides the questionable motives that are alleged to have partly inspired the action of that pontiff, also the bitter memories that tarried in the minds of European monarchs after their defeat on the question of investitures, and the death-blow dealt thereby to the feudal system. The entire antipathy aroused, for this and other reasons, against the Holy See in the time of Leo X found vent in the attack initiated by Luther on indulgences.

An indulgence may be acquired directly by the living and applied by them, with the consent of the Church, to the souls of the faithful departed. All Catholic theologians are unanimous in the opinion that an indulgence should not be granted without grave and substantial reasons, since the ordinary Christian economy demands that each individual should make personal reparation for the temporal debt due for his sins. Moreover, in order to participate fruitfully in an indulgence, certain conditions and dispositions are necessary on the part of the subject. He must be in the state of grace, have a genuine desire to gain the indulgence, and perform certain acts prescribed by the Holy See.

The application of indulgences to the dead is not a judicial act of the Church, whose jurisdiction is limited to the members of the militant or visible Church on earth. Remission of the temporal debt due to God for sin by the suffering members of Christ's mystical body in Purgatory is communicated to them by the Church by way of suffrage or supplication. In other words, she authorizes the living to join their petitions with hers that God may graciously accept the indulgences which they gain and in the measure in which they gain them, in behalf of the souls of the faithful departed. Indulgences are now dispensed partly by way of absolution and partly by way of commutation. The well-known distinction between partial and plenary indulgences should be understood in an objective sense. The degree in which any indulgence is actually gained or subjectively appropriated by the individual depends on his subjective disposition, according to the theological maxim: whatever is received is received according to the measure of the recipient. The most solemn of all plenary indulgences is that which is granted on the occasion of a jubilee such as that which was proclaimed for 1904 by His Holiness Pius X to mark the 50th anniversary of the definition of the Immaculate Conception by Pius IX.

INDULGENCE, Declaration of. See DECLARATION OF INDULGENCES.

INDULINES, dyestuffs, blue, bluish-red to black in shade. They were discovered in 1863 by J. Dale and H. Caro, and carry an English patent (No. 3307). They are formed by the interaction of para-amino azo compounds with primary monamines in the presence of a small quantity of mineral acid.

INDULT, a papal license, as when the Pope authorizes the bishop to grant certain relaxations during the Lenten fast required by physical necessity.

INDUNA, a word (Zulu-Bantu) signifying officer.

INDUS (Sanskrit, *Sindhu*), the chief stream of the northwest of India, and one of the great rivers of the world. It has a length of about 1,900 miles, and drains an area of more than 360,000 square miles. It arises in Tibet on the north of the Himalaya Mountains, nearly 100 miles northwest from the sources of the upper Brahmaputra (q.v.), on the north side of the mountain mass of Kailâs, 18,000 feet above sea-level. In the upper part of its course it takes a northwesterly direction along the northern foot of the main Himalayan range, enters the Kashmir territories, passes through Ladak, below the capital of which, Leh, it receives the Zanskar, farther on the Dras, after which it enters Baltistan. Here it receives, on the right, the Gilgit, from a glacier of the Karakoram, the largest tributary that joins it in the Himalayan regions, and takes the name of Indus or Sind. About 100 miles below this it takes a sudden bend toward the southwest, and after a course of about 180 miles more in this direction it leaves the loftier regions. At the British fortress of Attock in the Punjab — where it is crossed by a great railway bridge carrying the line to Peshawar — it is joined by the Kabul from Afghanistan, and here, 950 feet above the level of the sea, it is nearly 800 feet wide and from 30 to 60 feet deep according to the season. For the rest of its course (about 900 miles) it continues its southwesterly direction till it enters the Indian Ocean. At Kalabagh, 110 miles below Attock, it has a breadth of over 1,400 feet. Arriving in the low-lying country, its waters become charged with mud, and in the rainy season, and by the melting of the snow in the mountains, it overflows its banks. Near Mithankot it receives on the east the Panjnad, or united stream of the Five Rivers of the Punjab. Below the confluence it has a width of over 1,900 yards when the water is low. In Sind it gives off several extensive arms or canals, which are of great value for irrigation; and below Hyderabad it divides into a number of shifting mouths or estuaries, the most navigable of which is at present the Yatho mouth. The delta, formed by the enormous amount of alluvium brought down by the river, has a coast-line of about 130 miles, and the point or head of it at Tatta is 70 miles from the sea. The tide rises to this distance. The Indus loses much water from passing through dry and desert regions, and much is also drawn off for irrigation; accordingly it brings down much less water to the sea than the Ganges. Vessels drawing more than seven feet of water cannot generally enter any of its mouths; but steamers of light draft ascend from Hyderabad to Multan. A railway ascends the valley of the Indus from the important port of Karachi to Peshawar.

INDUSTRIAL DISTRIBUTION. The title Industrial Distribution, as here used, refers to the agencies and policies used by manufacturers in the marketing of their goods. If a comprehensive discussion of modern marketing methods were contemplated it would be in order to define the functions of the various institutions which serve in common all branches of commercial activity and then to set forth the practices used for the distribution of agricultural products, the methods used by manufacturers, and the organization and management of wholesale and retail trade. This all refers to the merchandising of movable commodities and takes no account of the interesting methods which have been devised for the sale of other goods, such as real estate, transportation, securities, professional services, entertainment, etc.

The Institutes of Trade.— In considering the manufacturer's problem specifically, it is worth while to begin with mention of the underlying institutes of trade. The first of these is the accepted system of weights and measures. Based in part upon legal enactment, and in part upon custom, the commercial measure is the unit to which price is usually attached. If it be in any degree vague, representative trading is discouraged and the cumbersome methods of lot inspection and of dickering and bargaining prevail. Modern trade is carried on with a system of weights and measures which is in part antiquated and in whole heterogeneous. The defects of the system have long stimulated reformers to work for a comprehensive and logical plan, such as the metric system appears to present. The trading community, however, is wedded to custom and is mindful of the inconvenience of the transitional period, of the capital invested in scales, containers, etc., and of the obsolescence which would overtake existing records if a change were made.

The System of Grades.— The second institute of trade is the system of grades, by which differences in quality are made definite and expressed. Without the foundation of legal enactment, which stabilizes our weights and measures, and with only so much public control as will prevent the grosser forms of fraud, the system of grades used in commerce is elastic. Old grades are continually being dropped and the names and definitions forgotten, while new grades with appropriate words or phases to designate them are introduced as advances in the manufacturing art require. The terminology of commercial grading is enormous: a book of large size is required to define the better-known kinds of textile fabrics. The legitimate terminology of grading is further overlaid by a vast variety of expressions used by traders either as a part of the game of trade puffery or as an endeavor to coin a trade name and get it introduced into the language as an indispensable trade term. Practically all of our systems of grades took their general form in an earlier day when few qualities were offered, and those were decidedly distinct from each other in physical properties. The need for a finer gradation of the quality scale has given rise to split grades or intermediate grades. In addition to these legitimate grades, the market has to cope with the skin grades of dishonest traders. Skin grades are qualities pitched so slightly below the recognized standard grades that while they may pass for what they are among traders and at an appropriate abatement of the standard-grade price they are expected to deceive consumers and sell at full prices to the general public.

Prices.— The third institute of commerce, and the most important, is price. A price is the exchange value of a commodity expressed in terms of money. The common expression is that price marks the equilibrium of demand and supply. The factors which determine price are not simply the primary supply of producers and the ultimate demand of consumers, but all those speculative activities of traders who, in anticipation of the future increase or decrease of supply or demand, alternately hold back goods from the market or throw reserves upon it. Since the manufacturing industry is reasonably stable in its productive capacity and the retail and wholesale industry likewise in its distributive capacity, and since the habits of consumers tend to remain reasonably constant over short periods of time, if left undisturbed by outside conditions, we must look elsewhere for the factors of change which are responsible for price fluctuations. Two of the chief causes of these fluctuations are changes in the weather, which influence the production of raw materials, and derangements in the credit mechanism of industry. These factors of change the manufacturer should learn to watch as barometers predicting future market movements.

The Market.— The fourth and final institute of commerce, to be here mentioned, is the

market. A market is an assembly of traders actively engaged in trade, and so limited by location, by the class of articles dealt in and by the average size of sales that the action of any one trader promptly influences the action of others. From this interdependency of action there results the chief circumstance which characterizes a market, namely, that upon it a commodity has but one price at a given time. Discrepancies of price will of course result from imperfect competition, but a process of mutual value adjustment is the essence of market action. What is an efficient market? To answer this question it is necessary to recall that among the essential conditions for the efficient purchasing and selling of commodities there are required assortments to select from, protection for perishable articles, reliable measures of quantity and quality, transportation facilities, fair prices and flexible credit facilities. Assortments are judged by purchasers with reference to the market as a whole rather than as to the stock of any one firm. A city has the proper stocks only when its merchants go beyond the usual process of stocking what is called for, and make systematic study of the resources and requirements of the adjacent trade territory. Measurement of quality and quantity requires a variety of agencies, such as the grading rules and inspection service of produce exchanges. Efficient transportation is secured only in cities which plan comprehensive terminal facilities. Storage calls for special types of warehouses tied into the transportation system rather than, as is usually the case, operated as an annex to the buying and selling process. The formula for fair prices is to bring to bear upon each purchase and sale transaction all possible elements of supply and demand which are logically related to it. This means to bring the past and future supply of an article to bear upon the present price by warehousing. It calls for bringing diverse commodities to bear upon each other in so far as they are related, either in the productive sequence as raw materials and manufactured derivatives or as substitutes. The sequence can be drawn upon in the forward direction only where the converting (manufacturing) interests are active. The formula requires further that the price of the use of money for a period of time (which is interest) be brought to bear upon the probable fluctuations of the price of goods during that period. As the price of money for brief periods is chiefly the cost of appraising the security offered, those markets have the steadiest commodity prices where loanable capital is plentiful and where there exist the grading, measuring, storing, insuring, credit reporting and other facilities which make it safe to loan on stocks of merchandise. Finally, the prices of different markets should be brought to bear upon each other by an adequate system of reporting. From all of this it is evident that a market is a complex thing. A good market is rare. It does not just grow, as Topsy did. It is the result of intelligent joint effort on the part of its members.

The Manufacturer's Price Problems.—The manufacturer has his own characteristic relation to all of the institutes of commerce. It may perhaps be said that his chief commercial problems revolve around the subject of price. There are three of these problems which merit brief presentation. They are, first, the question of varying the price with the quantity sold; second, the effort to protect dealers' profits by charging different prices to different classes of buyers; third, the project of further protecting such profits by controlling the prices of resale or the prices charged by dealers when they sell to consumers.

Quantity Prices.—It has long been a custom of trade to give to trade buyers who purchase large quantities (case lots, car lots or entire output) a lower price than is accorded to the small buyer. This is justified as a rebate to the large buyer of a portion of the saving in agency expense, bookkeeping, collection expense, etc., which his large order involves for the manufacturer. Upon this saving rests one of the well-known types of economy of production on a large scale. To take advantage of it, a variety of trading organizations has been developed in the United States in recent decades. In the wholesale trade the great interstate jobbers have grown up to hunt for the larger orders, leaving intensive work with the small retailers to the local wholesalers. To equalize the competitive advantage the small wholesalers have, many of them, combined more or less loosely into buying groups pooling their orders in the hands of syndicate buyers. The syndicate buyer maintains buying offices in the larger markets. He either pools the orders sent to him by his patrons into large consolidated orders, or he peddles out large purchases which the financial embarrassments of manufacturers enable him to make at bargain prices. In the retail trade quantity prices have led to the growth of department stores which aim at local mass retail distribution. They have led, also, to the growth of mail order houses, which aim at national mass retail distribution. Finally they have led to the organization of chain store systems which aim to combine mass buying and local small-scale retail distribution. The retail institutions just mentioned not only work for quantity prices but to a considerable extent eliminate the jobber.

The result of the appearance of these quantity-buying, direct-purchasing institutions is that the regular trade—sometimes called "legitimate"—comprising the local wholesalers and the single-line and country-store retailers—has been awakened to hostility. This hostility has taken the form of expressions of opinion on the part of associations of wholesalers and retailers, and of more or less exclusive trading arrangements of the small retailers with those wholesale houses who do not sell to mail order houses and chain stores. It has also taken the form of discrimination against such manufacturer's goods as appear on the shelves of such stores. Inasmuch as the regular trade comprises the overwhelming majority of the merchandising business of the country, these hostile moves have been given respectful attention by the manufacturers. The answering policy of many manufacturers has been to charge one price to all trade buyers, regardless of the quantity purchased. This puts the small store upon an equality, in the first cost of merchandise, with its department store neighbor. Some manufacturers have adopted very elaborate policies for the protection of the small dealer, and have stimulated the antagonism of the small dealer against the large one, in order to pose as a friend and get the business.

It can be seen that excessive reductions of price for quantity tend to concentrate the buying function, as contrasted with the selling end of merchandising. By it buyer and salesman are forced apart. So the local store unit of the retail trade loses flexibility in assembling such stocks as the locality requires. Its stock, as illustrated by the chain-store stock, becomes standardized and a matter of safe staples chiefly. Quantity price operates to the disadvantage of the village and the sub-centres in the outskirts of cities. It is to the advantage of the large stores in down-town metropolitan districts. On the other hand the opposite policy of one price, regardless of quantity, prevents the large city from enjoying the advantage its mass of business entitles it to, and prevents the capable dealer who has built up a large business on merit from enjoying a portion of the advantage his large purchases give to those who supply him. It tends, therefore, to keep alive a large number of small, incompetent establishments based upon the principle of proximity to the consumer.

Classification of Customers.—The second price problem of the manufacturer, to which we have referred, has to do with the necessity of maintaining dealers' profits. Goods flow up hill in price, as water flows down hill. The difference between the price paid by a wholesaler and that paid by his customer who is a retailer is a spread, out of which must come the wholesaler's costs and profits. If a manufacturer sell to a retailer on the same terms as to the wholesaler who has been supplying him, it is obvious that the wholesaler cannot continue to patronize that manufacturer. If in a typical distributive chain we have manufacturer, commission merchant, wholesaler and retailer, there will normally be four price levels, each higher than the other, and each maintained at a certain spread with reference to the others by the normal operation of competition. Into this normal situation a disturbing influence has been introduced by the abnormal growth of certain retail and wholesale institutions, in response to the economy of quantity prices, and in response to superior managerial talent. These large institutions have very naturally tried to change their class as buyers and purchase on the same terms as institutions prior to them in the distributive chain. So we see everywhere retailers who advertise themselves "wholesalers and retailers," to facilitate an approach to manufacturers. It has been found difficult to frame a satisfactory definition of what a wholesaler is. Inasmuch as manufacturers are commonly admitted to buying privileges with other manufacturers and with wholesalers, all small shops and local repair men are anxious to be classed as manufacturers and to buy either from manufacturers' catalogues, or at least from the same traveling salesmen as serve the neighboring retailers. Hotels, likewise, are privileged buyers: therefore restaurants and boarding-houses put themselves forward as much as possible for the same privileges. Dealers and agents are usually advanced one class in the distributive chain: therefore an innumerable number of persons acquire agencies for the sale of wagons, automobiles, windmills and manufactured specialties, for the purpose of purchasing their private supplies at better advantage. Against this tendency to break down the classifications of trade merchants have been obliged to interpose an influence. This they have done by drawing up lists of classified buyers. Such lists are usually formed by the joint action of two trade associations and are promulgated to govern the conduct of the members with reference to the trade classes covered by the definitions.

Control of the Prices of Resale.—A third price problem has been forced upon manufacturers as a result of the intensity of competition between retailers. One of the modern tricks of retail selling is to offer one article or a few articles at a very low price, and feature the prices of these by advertising as "leaders." The psychology of the leader is that the customer will infer from the few low prices quoted that all prices in the store are equally moderate. In practice, the leader is supposed to bring the customer into the store where his cravings will be so intensified by the sight of merchandise that he not only purchases the leader, after which he came, but purchases a variety of other articles as well. These latter carry a good profit and recoup the loss on the leader, so that the result of the total transaction is a profit for the store. The best articles to choose as leaders are those branded or trade-marked articles which are known to be identical in whatever store they may be found. These will bring out in full force the price comparison, free from any possible argument that the quality may be better where the price is higher. When, therefore, a manufacturer builds up a reputation for uniform quality, and his goods become well known, his merchandise best serves the dealer as a leader. It might be concluded that if the dealer lowered the price he would simply sell more goods and so would confer a favor upon the manufacturer. The history of a leader is, however, that after it has served a temporary purpose of attracting attention, it is dropped. As it is impossible to at once restore normal prices for the article, the dealers who once featured it exclude it from stock, or if it have too well an established position with the consumer for this, relegate it to the background so that the losses on it will be as small as possible and push other things in preference to it. Distribution falls off, therefore, and the manufacturer is aroused to action. The action which manufacturers have taken has been along the line of endeavoring to dictate to wholesalers and retailers at what price they may sell, and to whom they may sell, and then to enforce these dictates by cutting off the supply of goods from those dealers who disobey orders. These efforts have brought manufacturers within the pale of the Federal laws which forbid contracts in restraint of trade. A considerable variety of devices has been invented by manufacturers in the endeavor to encumber the title to a movable chattel with restrictions, in connection with its sale, and without creating a bona-fide relation of principal and agent. These devices have been uniformly declared

null and void by the United States Supreme Court.

Miscellaneous Elements of Manufacturer's Distributive Campaigns.— Of the many minor distributive problems of the manufacturer, embracing such matters as the design and use of trade-marks, trade-names and brands, and the significance of packages as brand carriers and as a means of specializing an article out of its competitive class, there is not room to speak. Likewise the purport of style as a trade device for rendering goods in consumer's hands obsolete; of agency systems, such as prevail in the automobile and agricultural implement businesses; of list-price systems, used in the construction of catalogues; and of the trials encountered in administering discounts for cash and of preventing the cancellation of contracts can only be alluded to. In other articles the functions of advertising and of salesmanship as general aids to distribution are given appropriate attention.

INDUSTRIAL FATIGUE. No phase of industrial efficiency is attracting greater attention, both in this country and in Europe, than the question of fatigue. While comparatively little thought was given to this matter prior to the war, except by a few progressive manufacturers and exponents of scientific management, the necessity of meeting war-time emergencies led to a careful investigation of the subject of fatigue with a view to increasing the industrial output to the highest degree possible without making too great demands upon the health and strength of the workers.

A study of industrial fatigue was one of the purposes for which the British Health of Munition Workers Committee was appointed, in September 1915, and the 'Memorandum' published by the special committee entrusted with the investigation of this subject emphasized the importance of the effect of injudicious effort upon the character of the work performed. Among the conclusions of the committee were:

"The committee are bound to record their impression that the munition workers in general have been allowed to reach a state of reduced efficiency and lowered health, which might have been avoided without reduction of output by attention to the details of daily and weekly rests. The signs of fatigue are even more noticeable in the case of managers and foremen, and their practical results are probably more serious than in the case of the workmen.

"It is of great importance to note that a special and strenuous voluntary effort in industry, if it be maintained under a badly arranged time-table of work and rest, does not necessarily bring increased output over a long period, however praiseworthy the intention or effort may be. Under wrong conditions of work, with excessive overtime, it is to be expected, indeed, that some deliberate 'slacking' of the workers might actually give an improvement of output over a period of some length by sparing wasteful fatigue, just as the 'nursing' of a boat crew over a part of a long course may improve their performance. It can not under such circumstances be said that a workman so restraining himself, consciously or unconsciously, is doing more to damage the output, on the whole, than the employer who has arranged overlong hours of labor on the baseless assumption that long hours mean high output."

In the United States, the Council of National Defense recognized the importance of this subject soon after preparations for war began and started investigations in factories engaged in the manufacture of war supplies to determine how a maximum output might be obtained without unnecessary fatigue. The results of this series of studies and experiments was published in January 1918 by the sub-Committee on Industrial Fatigue. Like the British report, it draws the conclusions that while "it is often possible to increase output temporarily by increasing the work of the employee . . . such a method, if carried far, quickly defeats itself and in the long run is not profitable," as "fatigue is the greatest single obstacle to a maximum output."

The committee naturally lay emphasis upon the distinction between the harmless fatigue that is the normal effect of bodily activity and the unnatural fatigue that is the result of badly arranged hours of labor and other improper industrial habits, and it recommended various methods for the reduction of the latter, not only without decreasing the output but "even in some cases with an increase of it." These methods include:

1. Adjusting Hours of Labor.— While it is obvious that the length of working day that avoids fatigue varies with different kinds of work and can be determined only by careful study, the tendency to increase hours and introduce overtime work has not always proved profitable. "A man can do more work in two hours than in one hour," say the committee, but "it does not necessarily follow that he can do more in twelve hours than in ten, or more in ten hours than in eight. In fact, whenever the work is of such duration that fatigue begins to be pronounced, it has been shown again and again that shortening the working-period actually increases the amount of work done."

2. Discouraging Overtime.— The committee's investigations seem to justify the discouragement of overtime on the ground that, if the ordinary day's work has been properly adjusted, it will stop just short of undue fatigue and the overwork necessitated by overtime will produce injurious results by diminishing the worker's efficiency, in lessening the output and increasing the amount of spoiled work.

3. Eliminating Sunday Work.— In advocating the elimination of Sunday work as a dangerous expedient, the committee's findings agree with the report of the British Health of Munition Workers Committee, who found that "seven days' labor only produces six days' output," and, they added, "the evidence before the committee has led them strongly to hold that if the maximum output is to be secured and maintained for any length of time, a weekly period of rest must be allowed."

4. Bad Effects of Night Work.— While the committee recognized the necessity of operating many factories on day and night shifts to increase the output of war supplies, they felt that in the long run night work will prove detrimental to the health of the workers, and they recommended a consideration of the plan to alternate day and night work, changing the shifts at intervals, say every other week. The report called attention to the fact that the British committee made a careful statistical study of the output under both systems and found that "where the same night-shift continues to be employed the total output is less than where there is an alternation of day- and night-work."

5. Rest Periods.— The introduction of rest- or recess-periods during the ordinary working hours has also been found effective in reducing fatigue and improving the quality of the output. In many plants all workers engaged intensively during the entire work-period are compelled to take two recesses, one in the morning and one in the afternoon. Such rest-periods are not optional but compulsory. The workers are forced to leave their machines and to move about and relax. In some cases a little food or a cup of tea or cocoa is provided.

6. Providing Seats.—The committee advised that, wherever possible, seats be provided in order that operatives may not have to stand all day; and suggested that, instead of being of uniform height, the "seats should be adjusted to the individual worker," and, "where the worker's feet cannot reach the floor, foot-rests should be provided."

7. Value of Motion Studies.— The committee also recognized the value of motion studies and the importance of the element of variety in the work performed, a conclusion that is in harmony with the theories of scientific management. In 1916, Richard A. Feiss, general manager of the Clothcraft Shops, Cleveland, Ohio, speaking before the American Public Health Association, declared that "speed in itself is not injurious. . . . There are conditions under which operating at half the best possible speed is more fatiguing and more injurious to the worker's health than operating at the best possible speed under proper conditions." This idea is also maintained by the committee, who advise that proper studies of motions be made with a view to the elimination of all awkward, unrhythmical and unnecessary motions, that the work may "be done with the least possible waste of energy and time." It also advocates the introduction of a little variety into work that must become monotonous through being the constant and rapid repetition of the same movement, and suggests that alternating processes might diminish the fatigue without diminishing the output.

8. Sanitation and Ventilation.— The committee found that fatigue diminishes and efficiency increases in keeping with the improvement of the sanitary conditions of the factory and the ventilation of the workroom. Excessive heat and humidity should be avoided as far as possible and the air should be kept in motion. Lighting facilities, the supply of drinking water, providing lunch-rooms and rest-rooms and the general sanitary condition of the toilets and wash-rooms, all play a part in the general plan for the elimination of fatigue. See INDUSTRIAL HYGIENE; INDUSTRIES, WELFARE WORK IN.

JOHN R. MEADER.

INDUSTRIAL FRUITS, those products of the soil which are sown and planted and upon reaching maturity are garnered or harvested, such as grain, vegetables and other crops. They are distinct from the natural fruits, such as trees, grass, etc., and are considered as personal and not real property. See GROWING CROPS, LAW CONCERNING.

INDUSTRIAL HOUSING IN THE UNITED STATES. Industrial housing is usually understood to mean housing of workers by employers. The growth of the co-partnership movement in England and the strong advocacy of its introduction into the United States before the European War, and the federal government's own experiment in house building for wage-earners during the war compel a broader definition. Industrial housing to-day is housing which contributes to industry, no matter by whom erected or managed.

Using the term in its older sense, however, industrial housing has a history in the United States which begins with the establishment of industries outside the home. The first American cotton mill was erected at the falls of the Pawtucket in 1790. Its successors in Rhode Island and Massachusetts were scattered along the streams that furnished their motive power. Compelled to plant the mills at a distance from established seaboard and commercial towns, the pioneer manufacturers were also compelled to build houses to shelter their employes. So began the New England mill villages, some of the earliest of which still remain along the little rivers that empty into Narragansett and neighboring bays.

The houses in these villages were well built, and even to-day, when sanitary conveniences and a public water supply have been added, most of them meet modern requirements. Moreover, they are far from unattractive with their grassy open spaces, their gardens and their fine old trees. It was necessary in the days of pioneer industry to build good houses, for the only available labor was the Yankee farmer's boys and girls who had been prejudiced against factory work by the tales brought from England of the horrors of industrial life. So the early industrial villages of America were designed to prove that industrial life here need not duplicate that of the Old World. Nor were the employers satisfied with the erection of good dwellings, they gave even greater care to the management of those dwellings. Especially were the dormitories or boarding houses of the girls and unmarried women kept under most careful supervision, and rules were enforced that would satisfy strict Puritan parents. Even the family dwellings were kept under a close supervision which limited considerably the freedom of the tenants.

In the early days, however, this regulation, which went far into the details of life, was accepted not only because it assured a good moral tone for the new communities whose inhabitants were in the main young people, but also because the employers or their chief representatives were a part of the community and shared its life democratically. The factory girls of the day became the manager's guests in the evening. This combination of democratic paternalism did not last, however. Even before the advent of coal and of immigrants from

Ireland and the continent of Europe the system had begun to break down. Employees became restive at having the same man both employer and landlord. The strict regulation which was necessary at the beginning became irksome as the villages developed into established communities.

The use of coal as a source of power caused some of these villages to develop into cities, Lawrence, Lowell, Pawtucket; it caused others to disappear, the owners finding it advisable to move to a place where railroad or water transportation was more accessible. When the villages grew into towns or the mills were moved to towns, the commercial builder appeared. To him the employees frequently turned with relief even when his houses were not so well built or cost more than those of the mill.

The mill owner also frequently welcomed this opportunity to drop the rôle of landlord. For there had been gradually developing a gulf between employer and employed. Though in the early days an owner often lived in Boston or Providence, the common traditions of a New England ancestry served to bridge this distance. But with the coming of the Irish with their different traditions and their different standards of living, the bond was weakened. When to the Irish succeeded Poles and Italians and even peoples of the Levant, the old democratic fellowship in the enterprise usually vanished entirely. The Lawrences of the new era became "pay envelope" cities, even the managers and heads of departments made their homes outside the mill communities. Then grew up the conception that the employer's concern in his employees ceased at the mill gates; cottages owned by the mill stood vacant or were turned into storerooms.

But this sharp cleavage of interests also proved impractical. With no community of interest there could be little or no mutual understanding, and labor troubles increased. Coincidently housing standards declined. The speculative builder, having no motive other than to secure the greatest amount possible for his property, developed the wooden three-deckers in place of the cottages and crowded them so close together that in some of the mill cities not only did gardens and yards disappear, but the windows of one house were practically boarded up by the walls of its neighbors, and what were once alleys became the thoroughfares giving access to solid lines of rear dwellings. The mill owners and their chief lieutenants, living far away from these conditions, persuaded that the matter was no concern of theirs, left the community without its natural leaders.

Then again the pendulum began to swing back toward its starting point. Compared with the suffocating, swarming, ill-regulated industrial towns and cities, the remaining old spacious mill villages had a new attraction. In some of them were the descendants of the original operatives. So new industrial villages were founded, some by employers who thought that in this way they would prevent labor troubles, some by men inspired by the more altruistic motive of rescuing their workers from intolerable living conditions. The spirit of the founders varied from the extreme paternalism of Pullman, which led to disillusion and failure, to the liberality of H. O. Nelson at Leclaire, which is still bearing fruit. This new group of industrial villages contains several which are notable for their beauty.

At the time the World War began not only was the number of industrial villages increasing rapidly, but discussion as to methods of financing and management were producing results that promised to do away with most of the dissatisfaction under the old régime. The old method of individual home ownership was falling into disuse and organized labor had definitely pronounced against it. Direct ownership of the employee's home by his employer had satisfied neither party. A first step away from this was taken by the incorporation of subsidiary companies so that the dwellings were no longer managed from the factory office. A further step had been taken in two or three instances by an adaptation of the English co-partnership plan by which the tenants were gradually to become stockholders in the company that owns the houses. Then came America's entrance into the war.

During the years 1917–18 the United States government embarked upon a great experiment, the erection and management of wage-earners' dwellings. The signing of the armistice in November of the latter year left the experiment far from complete. One of the Federal agencies, the Emergency Fleet Corporation, had carried some of its developments to a point approximating physical completion, a small proportion of its dwellings were actually occupied. The other Federal agency, the United States Housing Corporation, handicapped by a later start, had not yet housed a single workingman's family. Neither agency had worked out a plan of management, though they had agreed for the time being not to sell any of their holdings. The Emergency Fleet Corporation controlled its properties through subsidiary corporations of the various shipbuilding companies through which it operated. The Housing Corporation owned its properties itself. The signing of the armistice led to some curtailment of the Fleet Corporation's housing developments, though in the main these were carried through, as shipbuilding did not cease with the war and the new dwellings were needed to hold the workers. The Housing Corporation, however, not only curtailed its projects, but wherever possible without too great loss, cancelled them entirely.

In spite of the failure to carry this great experiment to completion it exercised a considerable influence in various ways. First and most important it gave a notable impetus to the movement for government aid which before the war had been making only a slow and uncertain progress, Massachusetts being the only State in the Union which had committed itself, and it had done so only to the extent of $50,000 with which a small group of houses were built at Lowell. The war, however, demonstrated clearly both the vital importance of good housing to productive industry and the inability of private builders to meet the need. Second, it brought into the service of the wage-earner some of the leading architects, engineers and landscape designers of the country, who both because of lack of private work and the call of patriotism, for the first time turned their thoughts to the needs of men of small means.

The reverse side of the shield was financial. The need for the houses was urgent. Good planning, good designing, took little more time than no plan or design, perhaps rather less as they practically compelled an orderly procedure which prevented confusion and false starts. But speed forced into the background all thoughts of economy. The houses, with the exception of those in a few of the earlier developments, were good, but when completed their cost was high. This left a financial problem which cooled the ardor of many who otherwise would have been tempted to imitate the government's villages.

Yet the effect was notable, not alone in that these government-built villages have set a high standard by which to measure other industrial housing developments, but by breaking the taboo which had prevented government aid to housing in America, almost universal, though this long had been in other parts of the world.

In this article nothing has been said of the mining villages, which form a group by themselves. As with the pioneer industrial villages, the mining towns were of necessity built by the companies because they must be located with reference only to the mine. With them, however, there was the additional reason that their life was uncertain, depending upon the time it might take to exhaust the mine. This second reason also led to a policy of making these towns as cheap as possible, so they became a by-word for their squalor and ugliness. Yet before 1914 the new interest in industrial towns had affected them and great improvement had begun. See also CITY PLANNING; GARDEN CITIES.

JOHN IHLDER,
Executive Secretary, Philadelphia Housing Association.

INDUSTRIAL HYGIENE. The policy of providing healthful and comfortable working quarters for employees in commercial and manufacturing establishments has been developed within comparatively few years. Previously little thought was given to such matters and, in factories especially, operatives were crowded together in any kind of a shop that chance or a desire for economy might provide and the fact that many of these working places were both dismal and unsanitary had but little weight with the average employer.

To-day these conditions are changing so rapidly that poorly lighted, inadequately heated, improperly ventilated or otherwise unhealthful workshops are coming to be the rare exceptions to the rule. Instead, in the average shop, adequate toilet and washing facilities are now provided, problems of lighting and ventilation are solved by expert engineers, even such questions as the regulation of heat and humidity being given serious consideration, and every effort is made to see that the working conditions are such as not to impair the health and efficiency of the employee.

While the matter of hygienic and sanitary equipment has been fixed to a great extent in New York, New Jersey, Pennsylvania, Massachusetts and Wisconsin, where the legislatures have enacted laws setting a standard, not only for industry as a whole but, in many instances, for particular branches of industry, the improvements in these directions are in no sense confined to establishments that have been compelled by statute to adopt more modern methods. Even in communities that are unregulated by law or industrial code, similar improvements are constantly being made, for experience has so clearly demonstrated that these changes in working conditions quickly pay for themselves in the character of the service performed by the working force that even those employers who feel that they owe no such moral obligation to their employees have learned the lesson that proper hygienic and sanitary workshops make for greater and better production, and are

	Lavatories	Toilets	Drinking fountains	Lockers
Type	Individual	All porcelain; no wood	Bubbling type, arranged so lips do not touch metal.	Perforated metal, slanting top to prevent accumulation of refuse.
Located	In central building near lockers.	Substations near workers.	Where convenient to workers.	In central building.
Number	1 for 15 men	1 for 20 men	1 for 30 men	1 per man. If possible, one compartment for work and one for shop clothing.
Accessories	Hot and cold water, liquid soap, paper towels.	Automatic flush		Locked. Forced hot air ventilation to dry wet garments.
Plumbing	Open type, plain.			
Special features	Porcelain	Must have forced air ventilation.	In clean, light places.	It is advisable to arrange locker so that men coming off work at same time have every second or third locker to prevent crowding.
Note	Average time per man at washbasin 2½ minutes.	Compartments should not have doors as easier to keep clean.		If lockers are near washbasins a larger number can use both without waiting.

taking the steps necessary for the adoption of the methods that are everywhere proving so mutually advantageous.

In fact, these questions have assumed proportions of so great importance that, in several instances, employers' associations have conducted thorough surveys and adopted standards for the improvement of working conditions, even in communities unaffected by legislative statute. For example, the Welfare Managers' Group of the Detroit (Mich.) Executives' Club made a survey which included all of the important plants in that city, and, as a result, the preceding sanitary arrangements were suggested as necessary for the proper equipment of a manufacturing plant.

The committee also reported:

"The objections to paper towels, 'that we do not get our hands dry enough to prevent chapping,' can be done away with by a well-ventilated, warm dressing room, where the hands will dry while dressing. Where there are corners into which waste paper and refuse are thrown this can be largely eliminated by painting these corners white and lighting them well. One does not throw waste into clean corners. Tile floors should be laid in all washrooms, etc., where possible; otherwise, cement, well drained. Oily floors should be swept and scraped daily. Where cement floors are used, rubber pads for the men to stand on will help in increasing comfort and efficiency. All scrap metal should be kept clear of the workers."

The Detroit committee also included "good lunch room and recreation facilities among our prophylactic treatment," on the ground that properly prepared, carefully selected food and healthful recreation are important factors in the development of an effective hygienic and sanitary program.

In plants where workers are exposed to dangerous dusts or noxious fumes the installation of a lunch room is regarded as most essential, as all authorities agree that the cold luncheon eaten in the workroom, or in an unpleasant environment, must have a direct effect in reducing the physical fitness necessary to production. Where lunch rooms are not provided, it is advised that gas stoves or steam tables on which foods brought from home may be heated should be installed, and it is declared that even the policy of furnishing nothing more than milk, coffee, tea or soup at a nominal charge has invariably been found an economy to the employer. Where lunch room facilities are provided, however, care should be taken to see that the food served is of excellent quality, both in material and method of cooking, for otherwise it would be difficult to overcome the temptation to hurried eating, but it has generally been found that where food is selected for its nutritive value and is prepared with a view to ready digestion, satisfactory improvement in the health of the working force is noted, with a corresponding reduction of time lost through illness and intemperance.

While the part played by fresh air in the prevention of occupational disease is generally admitted, the vague character of the standards in vogue in different States has proved a great handicap to the manufacturer who is desirous of adopting the system best suited to the needs of his operatives. As Roach points out (*Industrial Management*, October 1917): "The terms 'adequate' and 'sufficient' have left him free to spend thousands of dollars on experiments, the results of which have too often given little of the protection to the health of the worker promised by irresponsible contractors."

Expensive systems of air conditioning are naturally unnecessary in the ordinary workroom where nothing more than fresh air is needed, and they are rarely installed except where the process of manufacture requires absolutely dustless conditions or a stable degree of humidity. For ordinary purposes, draft deflectors placed at both top and bottom of windows afford satisfactory ventilation.

While plants with non-dusty processes often find this window equipment all that is necessary for ventilation, it is admitted that it cannot be depended upon where noxious vapors or excessive humidity have to be considered. The same objection can be made to so-called "natural draft" ventilators, which, while they often work satisfactorily when there is a sufficient breeze present, fail to accomplish their purpose on humid days when the noxious air lies close to the floor.

Where industrial dust or vapors must be removed from the air the adoption of the most approved dust exhaust system becomes necessary. In this connection Roach says:

"The usual and inexpert practice in building a dust exhaust system, such as is required for buffing, polishing or grinding wheels, is to proportion the main section pipe so that at all cross-sectional points it only equals the combined areas of the entering branch pipes; while the inlet of the exhauster used on such a system has an area that but equals the combined areas of all the branch pipes used on the system. For example, for 25 4-inch branch pipes the largest diameter of main pipe and exhauster would be 20 inches. A 50-inch exhauster would have an inlet 20 inches in diameter; if it were necessary to get a suction-head at each branch pipe sufficiently strong to displace 2 inches of water in a pressure gauge (commonly called a U-shaped tube) it would require an actual velocity of 4,000 lineal feet per minute in the branches, and it would be necessary for the exhauster to handle 8,720 cubic feet of air per minute. It would require approximately 16 horse power to obtain these results, which in itself is an important item.

"This kind of a system should no longer be permitted. Standards based on actual working tests and experience prove that efficiency requires for 25 4-inch pipes a main pipe with an area 20 per cent larger at all its cross-sectional points, than the combined areas of entering branch pipes. The inlet of the exhauster attached to the system must have an area 20 per cent larger than the combined areas of all the branch connections on the system. This kind of system would require a 55-inch exhauster having a main pipe 22 inches in diameter and, to obtain a suction sufficient to displace 2 inches of water in a U-shaped tube, the air in each branch pipe would be obliged to have a velocity of 4,000 lineal feet per minute. The exhauster would handle 8,720 cubic feet of air a minute and would take about 12 horse power to operate it."

In many plants the hygienic and sanitary control is in the hands of the industrial physician whose duties comprise a more or less close supervision over the physical condition of the operatives from the day they enter the employ of the company. Many concerns have adopted the policy of examining all applicants for employment before engaging them, with a view to determining the physical fitness of the man for the job which he is to be expected to perform; a smaller number of establishments insist upon periodic re-examination, in order that his physical defects may be detected as quickly as possible and he may be assisted in remedying them, while all employers who employ the physician have found that his services in accident prevention and general health supervision have proved of sufficient value to more than offset the cost of the service. So well established has this fact become that even plants that are too small to employ a permanent physician have established dispensaries, where they meet all requirements for first-aid through a plant nurse, the physician being called upon for examinations, or, when necessary, for more important services.

According to the report of the committee of the Detroit Executives' Club, a plant employing from 1,400 to 2,000 persons should devote three rooms to hospital purposes — a reception room, an examining room and a surgery or dressing room.

"The furniture needed in a reception room is enough chairs so that patients will not have to stand, and a stretcher. The examining room should have a rest cot, scales and other instrumental equipment, with two or more booths to facilitate examinations. The surgery room needs an operating table, an instrument case with necessary first-aid instruments, drugs and dressings, one or two pedestal wash basins and one waste can."

So general has health supervision become in industry that the physicians engaged in such activities have organized an association, the Conference Board of Physicians in Industrial Practice, and it was in their behalf that Magnus W. Alexander, in August 1917, published his report on the "Cost of Health Supervision in Industry."

The purpose of this report, as its compiler stated, was to inform employers of the actual cost of health supervision in the different industries. "To this end, the data were secured from plants engaged in many industries, in light, medium and heavy work, in comparatively safe as well as hazardous occupations, and in shops of various sizes and character, located in various parts of the United States. . . . The chief significance of these data, from a general viewpoint, is that it is possible to give such a large amount of medical and surgical service at a cost which averages only $2.21 per employee per year. . . . Where the average cost appears to be unusually high . . . the size and character of the medical staff is usually the determining factor. In some cases the cost is influenced greatly by the number of injuries treated in private or public hospitals, in others, by the amount of care given to all injuries, whether serious or slight, or by the extension of the service to include physical examination of all employees, treatment of sickness of employees at the plant and at home, and even by medical care of employees' families, or by a combination of all these features."

Mr. Alexander concludes his report with the statement that "convincing proof of the economic value of health supervision in industry is afforded by the fact that it was found that no employer had abandoned the health supervision activities established in his plant. On the contrary, the prevailing tendency has been to invest even more money in extending the service."

A summary of the report is as follows:

INDUSTRY	No. of establishments reporting	Total average number of employees	Total cases of all kinds	Total medical and surgical cost	Average annual cost per employee
Metal trades	47	294,646	1,988,991	$541,771	$1 84
Rolling mills	7	49,317	358,574	137,047	2 78
Smelting and refining	1	1,270	2,832	6,932	5 46
Light and power	7	24,921	49,046	92,601	3 72
Transportation	5	35,795	81,591	69,633	1 95
Chemicals	6	10,572	78,744	34,797	3 29
Food	5	13,650	69,565	39,875	2 92
Rubber	5	27,462	234,069	76,089	2 77
Textiles	4	8,939	67,380	24,177	2 70
Paint	2	4,023	10,255	29,635	7 37
Leather	2	3,026	9,440	6,102	2 02
Publishing	2	3,358	6,742	3,473	1 03
Coal mining	1	2,454	2,842	4,637	1 89
Gold mining	1	2,500	62,126	35,590	14 24
Coal and iron mining	1	11,000	131,898	130,000	11 82
Miscellaneous	3	2,611	11,019	6,126	2 35
	99	495,544	3,165,114	$1,238,485	$2 50

In several plants in this country, health supervision includes the care of the teeth and eyes, examinations being made by specialists in the employ of the firm; subsequent treatments usually being at the expense of the employee, though at greatly reduced rates.

The adoption of sanitary standards was the means taken to overcome the "sweat-shop" conditions that had operated so injuriously to several branches of the tailoring industry and, wherever there has been sufficient organization to adopt and enforce such regulations effective results have been reported. The standards adopted by the Joint Board of Sanitary Control in the cloak, suit and skirt industry of Greater New York forbid cellar shops and tend to prevent the establishment of workrooms under conditions that might prove injurious to health. They provide that shops located in buildings more than one story in height must have fire-escapes properly equipped with ladders to an adjoining building or with carefully adjusted full-length drop ladders. Where automatic sprinklers are not provided, there must be a sufficient number of chemical extinguishers or fire-buckets, and special caretakers should be appointed in each shop to see that the fire-buckets are kept filled and are ready for use in case of fire. No smoking is permitted in the workshops, doors must not be locked during working hours, signs marking exits and fire-escapes are to be conspicuously placed about the shop, fire-proof receptacles with tin lining and covers must be provided for

rubbish, all openings and exits to fire-escapes must be left unobstructed by tables, machines, partitions or iron bars, and stairs are to be provided with secure handrails and safe treads.

As to lighting, the regulations stipulate that there shall be sufficient window space to ensure that the shop shall be well lighted from 9 A.M. to 4 P.M.; where artificial illumination is needed, arc-lights or incandescent mantles shall be used for gas, and all lights should not only be well shaded, but should be placed above the operatives and not too near them.

In the matter of ventilation it is provided that at least 400 cubic feet of space, exclusive of bulky furniture and materials, shall be provided for every person within the shop, and all work-rooms are to be thoroughly aired, before and after work hours and during the lunch hour, by the opening of both windows and doors.

Other regulations provide that (1) no coal shall be used for direct heating of irons, and where stoves are used for this purpose they must be surrounded by a metal sheet at least five feet high; (2) walls and ceilings of shops and toilets should be kept clean; the floors to be scrubbed weekly, swept daily and kept free of refuse, while the toilets should be flushed. It is advised that a special caretaker should be designated to oversee this work. (3) A sufficient number of water-supplied wash-basins are to be provided in convenient and light locations; (4) separate dressing rooms are to be provided for the sexes, with suitable hangers for the street clothes of employees; (5) there shall be separate toilet arrangements, with solid partitions from floor to ceiling, as well as separate vestibules and doors, and (6) all seats provided in the work-rooms are to have backs.

JOHN R. MEADER.

INDUSTRIAL INSURANCE. See INSURANCE, INDUSTRIAL.

INDUSTRIAL ORGANIZATION AND ADMINISTRATION. In the consideration of the organization and management of manufacturing establishments let us, after glancing at the evolution of American business administration, divide the subject into three parts, namely, the handling of finances, the administration of the manufacturing processes, and the control of the personal relations. The management of the selling and advertising functions, which should be considered in a general review of the subject, are treated under the heading INDUSTRIAL DISTRIBUTION.

Historical Review.— In the early decades of American business, the organizations used for administrative control were of the simplest character. Private and family-owned enterprises or small partnerships operated plants which might be described as shops. The first large undertakings, which required the corporate form, and which necessitated any considerable formality of financing, were the toll-roads, canal companies and the railroads. The chief factor which caused an increase in the size of businesses during the half-century 1840–90 was the invention of machinery. The large-scale operation which machinery and the use of mechanical sources of power suggest has been realized because of the enormous domestic market, the ample capital available, the freedom of the country from tradition and the existence of a spirit of daring. By the decade 1895–1905 these experiments had sufficiently developed the technical aspects of manufacturing, that engineers could boldly plan groups of specialized plants under united control. Meantime the accountants had learned how to keep untangled the most heterogeneous affairs; and the distributive or marketing machinery was devised for handling the entire domestic market in a single campaign. Since the possible economies from the elimination of competition were very large, there occurred the so-called "trust movement," which resulted in the consolidation of many hundreds of individual plants into a small number of great consolidated corporations. In the process of putting these enterprises together, and of operating them, the art of corporation financing, and its underlying technique of accounting, have achieved a forced growth. Overlapping this period in part, but operating most intensively from 1910 to 1914, there occurred the movement known as "scientific management." Broadly speaking the purport of this movement is that a group of engineers applied the precise and systematic methods of investigation and calculation recognized in the engineering sciences to the study of shop processes, and that by so doing they uncovered astonishing inefficiencies and were able to recommend a system of functionalization of shop executives and a policy of standardization upon the best methods which systematic study should discover. Scientific management is an effort to apply the scientific method to a certain portion of shop practice. It met with determined opposition because it did not adequately apply the knowledge and spirit of the times in its handling of the wage-earner. A further account of this movement may be found under the heading SCIENTIFIC MANAGEMENT. At the present time the interest of business executives in the evolution of new methods centres upon "human engineering." There has been an accumulation of knowledge concerning hygiene and public medicine, the causes of fatigue and accidents and the wastes of the hiring-and-firing methods in vogue, which demands application. It is realized that men should be carefully chosen for their work and given special training for it. Organized labor has enforced the idea upon the public mind that the laborer should have a voice in determining the conditions in which he works. And finally there are new ideals of the square deal and of service which are making their way among the more advanced employers.

Departments of Business Administration. —The ordinary functions of business administration fall into four classes: (1) Financing — in charge of the chief officers, working in close relations to the board of directors. (2) Manufacturing — in charge of a general manager or superintendent, directing a corps of foremen in the shops. (3) Selling — under the direction of a sales manager, with district agents and salesmen. (4) Personnel Relations — in charge of an employment manager or superintendent of personnel.

Financial Organization and Management. —If the inauguration of a business take the usual course of large modern enterprises, there will first appear upon the scene a promoter, who discovers undeveloped properties or poorly-managed concerns, forms a plan for their development, secures options upon them and puts his project before capitalists. Capital may be represented by a syndicate manager, who acts for a group of banks and large private investors in investigating the projects presented. If a project be found meritorious, its financing will be taken over on conditions which ensure adequate control of the subsequent operations of development. A corporation will then be formed which, under its charter powers, elects officers, enters into contracts, issues securities, receives funds, secures plant and equipment and otherwise prepares to do business.

The liabilities of a business corporation may be briefly listed as bonds, short-term notes, preferred stock, common stock, commercial paper and open accounts. The bonds of manufacturing enterprises (unless the business of certain public utilities be included therewith) should represent but a small fraction of the total capital, for the reason that the earnings of such businesses have, in the past, been subject to violent fluctuations. Preferred stocks are a business man's risk. They may be described as intermediate in security between bonds and common stocks. They will, in many cases, represent the cash and property contributed to the business by the group of interests connected with its organization and development. Common stocks receive dividends only after interest on the bonds and dividends on the preferred stock have been paid. There is no margin of safety to protect them. Their hazard is not so much the correctness of the process of valuing assets as it is the skill of the management in earning income. They are an appropriate investment only for men of means who are intimately associated with industrial management.

The financial authorities of a business are responsible to allot the funds raised from the issue of securities as advantageously as possible to the various requirements. A portion will go into buildings and equipment and other relatively permanent forms. This may be designated as fixed capital. Another portion must be reserved for raw materials, finished stock, pay roll and credit advances to customers. This is circulating capital. Fixed capital loses value slowly as a result of wear and tear. Circulating capital changes its form of investment rapidly. A balance in the bank last week may have been paid out as wages and be now represented by goods in the warehouse. Next week, if the goods are sold, it may take the form of a credit advance to a customer.

As fixed capital is relatively enduring, a large amount of funds should not be put into such a form until it is certain that the enterprise is to be of a permanent nature. Fixed capital may be of various degrees of specialization. The more specialized the form the more difficult it is to sell, and the more its selling price depends upon the hazard of a single set of market conditions. The degree to which it is proper to specialize capital is a function of the conference felt in the soundness of the project. The utilization of fixed capital is a process requiring the continuous supplying of circulating capital. Materials and labor must be provided to support the process of production. A plant is valueless when not in motion. To keep it under headway money must be constantly poured into it in amounts which in the average case may equal the total capital of the business annually. It is a somewhat common error of business finance to place an unduly large proportion of the assets in fixed form. The homely caution of Poor Richard may well be remembered, "It is easier to build two chimneys than maintain one in fuel." The financial organization of a private business connects with the general financial machinery of the country through the company's published reports, through the certified public accountant who vouches for the report he signs and through the general banking system. It is further connected by the investment bankers who purchase the securities after investigation and sell them to the investing public, by the stock exchanges which exert some slight control over the probity of the methods of the corporations whose securities they admit to listing privileges, by State commissions which are rapidly taking over the functions of authorizing security issue and by the general machinery of law.

Administration of Manufacturing Processes.— The highest authority in a business, on matters pertaining to productive processes, may be known as the general superintendent or works manager. In the initial stages of the business this officer will have the leading influence in determining the location of plants, the layout and character of buildings and the selection of machinery. When preliminary plans result in the construction of a mechanical automaton, and it becomes necessary to add men and materials and to indicate methods of production, in order that the enterprise can become a going concern, the general superintendent will take on a much expanded range of responsibilities. He will be expected to keep the physical equipment and productive processes up to standard and to employ an adequate force of foremen, laborers and skilled men of the various crafts. He will control the progress of work in relation to the demands of the sales department by a schedule and a system of orders, which control all productive labor and the use of material. The design of articles and the accuracy of manufacture is effected through a designing department and a system of inspectors. As a means of improvement he will use time studies and motion studies. The information thus accumulated he will embody in standards, which will be promulgated as the prescribed methods. The ideal is standardization, which is such an effective control of performance that every case conforms to the rule laid down. These prescribed methods will be communicated by general or standing orders and by shop orders. In a business of any size, orders should be written. The standing orders, when gathered together, will compose a "book of rules." The shop orders will be supplemented by instruction cards, to convey precise information as to the materials to be used, the machine or tool to employ, the process to select, the time the task should take, the machine adjustments, etc., etc. A particular instruction card will be prepared in advance for each task, and will be issued from the planning room, for the workman's convenience, each time the job is given out.

The planning room is the chief service aid of the superintendent and the foreman on technical matters. It may, in a typical instance, contain a routing or order-of-work clerk in charge of the planning board, an instruction card clerk, a clerk in charge of time slips and cost records; and it will probably serve also as headquarters for the engineer who calculates the proper speed of machinery, and the time study man who studies manual operations.

From the foregoing statement of duties it can be seen that the general superintendent has a very wide range of responsibilities. To be able to function efficiently, in the face of the enormous evolution of science and technique which has taken place in recent years, he should confine himself to general supervision, entrusting details to a staff of specialists. There has grown up in the best-managed businesses a number of service departments or staff aids for the express purpose of relieving the general superintendent. Such are the tool room, the stores department, the engineering department, the designing and drafting room, the inspection department and the planning room. Usually also the cost department and the employment department will be answerable to him. To a considerable degree the difference in efficiency of manufacturing enterprises depends upon the ability of the superintendent to comprehend the functions of service departments, and his success in organizing about him a staff of specialists who relieve him and his foremen. An executive blockade exists in many businesses because the general superintendent and foremen are overloaded. The remedy is to apply the principal of specialization and division of labor in administration, as it is applied among the craftsmen and common laborers in the shops.

Administration of Personnel Relations.— Within the last 15 years, the attention of business executives has been increasingly drawn to the problem of employment management, or as it is sometimes called, "human engineering." For years the demand of labor organizations, and the waste and violence of strikes, have made the "labor problem" synonymous with a class contest over the sharing of the product. Recently, the relation between employer and employee has begun to take on a different character. It has been found that a great many things can be done which will benefit both. A field of harmonious policies has opened itself. The labor problem begins to appear to be a matter of the careful selection of men for their work, the provision of comfortable working conditions, the prevention of accidents, the safe-guarding of health, the careful setting of wages on the basis of an honest study of all the facts, including the cost of living, and a variety of activities which develop interest in work, loyalty to a common cause, and the mutual welfare. Experience has proved that these problems can best be handled by having a separate department of the business, which can devote itself to them; and by putting in charge of this department a first-class executive. The movement to install such officers is a resultant of progress in accounting, staff organization, functional foremanizing, vocational guidance, industrial training, the new wage systems, safety first, hygiene and medical aid, and the use of the committee system of shop management. The functions of the employment department are, for the most part, not new in industry. They are now being gathered together under one authority so that they may be handled in a more expert manner, that they may be harmonized into a consistent policy, and that they may be made the definite responsibility of competent officers. Among the causes which are responsible for the attention now being given to personnel supervision is the extension of cost accounting to the factors which influence labor efficiency. The cost of labor turnover is being calculated. The cost of accidents, of sickness, of absenteeism, of improperly placed men and of strikes is being studied. The employment manager is, in one sense, a labor-cost accountant. The organization of an employment department does not involve an increase in the cost of doing business. On the contrary, it means an economy, by reason of a reduction in the number of persons to be trained, a saving of foremen's energy, a reduction in accidents and a gradual increase in the average skill and experience of employees. Proper employment conditions attract superior workmen, and generate a co-operative spirit; this affects favorably the rate of production, the waste of stock and the quality of output. See LABOR TURNOVER.

The employment manager is necessary to apply the art of mental testing and vocational guidance in ascertaining the fitness of prospective employees. He best can direct industrial training to provide the talent which the employment records show to be most needed. He knows the process of establishing fair base rates of wages, of working out wage scales, of checking minimum rates against the local cost of living, and of planning simple and specific production bonuses. The employment manager has come in with safety first, because it has been found that three-fourths of the accidents are due to the carelessness or ignorance of the working force. His department works along the lines of hygiene, sanitation, medical aid, canteens and health education, to cut down accidents, reduce fatigue and cure antagonism of mind. Employment supervision represents a movement in the direction of the democratic shop, in which a voice is given to labor in determining the working conditions. It is a means of applying that conception of truth and service which has revolutionized selling and advertising. As the customer is "sold" goods — that is to say is thoroughly convinced and satisfied — so a workman is "sold" his job. The latter has to be satisfied as to the task, the working conditions, the wages and the general policies, before he becomes a genuine employee.

The employment manager is coming in as a new staff man to relieve general executives. Staff or service departments are already familiar in the form of accounting departments, statistical departments and the like. This principle of staff service is now being carried over into the field of human engineering. General executives are demanding well-chosen men, men who are free from accidents and in sound health, men satisfied with their pay, and men so treated that they form a permanent and contented force, ready to co-operate loyally in the general plans of the enterprise. Of all the standardized agencies a service department can furnish to a general executive, the greatest is a first-class man. In a somewhat analogous way the employment manager represents a step in specializing the work of the foremen. His coming makes the foreman less of a jack of all trades, just as the coming of the tool room, the stock room and the designing department did. Under the new system, the foreman can no longer sell jobs, or protect pets, or cover up his own incompetence by discharging a man. When the foreman becomes accustomed to the new system he finds it a great relief. He gets a more even and dependable run of men than he could provide for himself, and he is free to become an expert in shop processes. See EMPLOYMENT MANAGER; EMPLOYMENT MANAGEMENT.

INDUSTRIAL PEACE, Experiments in. The desire to find a common ground of understanding between capital and labor with a view to reducing the enormous financial wastage resulting from needless labor strikes is the purpose back of every experiment in industrial peace that has been inaugurated during the past 20 years. The first efforts in this direction assumed the form of some type of profit-sharing, the idea being that the prospect of sharing in the profits of the employer would appeal to the self-interests of the workers and so inspire more loyal and efficient service. Theoretically, the idea appealed to many practical men, and various developments of the profit-sharing scheme have since been carried out. The failure of many of these projects has not had a permanently discouraging effect upon those who favor some such form of co-operative business effort, chiefly because of the fact that, in at least a majority of cases, the lack of success can be traced to local causes which proved stronger than the principles involved. Thus, the attempts of employers to use the profit-sharing ideal for advertising purposes or as a means of evading appeals for increases in wages, have invariably proved disastrous. At the same time, some of the largest concerns in the country have adopted this form of rewarding their employees, and with such satisfactory results that it is still in force. One reason why the number of failures charged against the profit-sharing idea is so great is that so many schemes that cannot properly be called profit-sharing have been classified under this designation. Thus, numerous forms of co-operative effort, including plans for participation in stock ownership through instalment purchase, bonus systems, pension schemes, and various projects of a welfare character have erroneously been classed as "profit-sharing."

The term "profit-sharing" was first defined by the International Co-operative Congress, which was held in Paris, in 1889, and was stated to be "an agreement freely entered into by which the employees receive a share, fixed in advance, of the profits," while the term "agreement," as used in this connection, was defined to cover "not only agreements binding in law but as including also cases where the agreement is only a moral obligation." The term "profit" was defined as "the actual net balance or gain realized by the operations of the undertaking"; "a share" as "a sum paid to the employees out of the profits," such share to be "dependent upon the amount of the profits" and "not indeterminate," or, in other words, "it must not be a share which an employer fixes, at the end of some period, at his absolute discretion, as distinguished from a prearranged basis," while the proportion of the total working force of a concern that must share in the benefits before real profit-sharing conditions can be established was declared to be "not less than 75 per cent." Making allowance for certain elasticities in interpreting this definition, necessitated by typically American conditions, the United States Bureau of Labor Statistics (Bulletin 208) reports that it found 60 genuine profit-sharing plans in operation in the United States. Of these, seven were established prior to 1900 while 29 have come into existence since 1911 and 21, or about one-third of the number, in the three years between 1914 and 1916. More than three-fifths of the concerns operating on a strict profit-sharing basis were located in three States, New York, Massachusetts and Ohio. Since the publication of this report, the number of plants adopting some form of genuine profit-sharing has been considerably augmented and advocates of this method of securing closer co-operation between employer and employee believe that the next government report will show more favorable conditions, not only in an increased rate of distribution but in other results more definitely indicative of the general practicability of the plan.

The National Association of Corporation Schools reported, in November 1918, that a recent survey of profit-sharing schemes showed that 39 plans had been abandoned, 10 because of labor troubles and strikes; seven because the employees were dissatisfied; five because the employers found that they operated unsatisfactorily; five because of failure under diminution of profits; four on account of lack of appreciation on the part of employees; two because of changes in business management, and one because the employees sold out their stock on a war market. The reasons for eight abandonments was not stated.

The Corporation School Bulletin states (November 1918) that while it is difficult to eliminate all the obstacles enumerated, they may be gotten around, and "in this," it continues, "we are making some progress through careful study of the operating conditions and of the factors and fundamentals underlying each particular business. We are learning through our mistakes. Workmen are being classified and consideration is being given to what is just and fair to each class of employees. The reward is being fixed in proportion to certain definite desired accomplishments, in regard to output, the cost of production and other factors the value of which to the firm concerned can be figured. In consequence

it will be possible to determine just what the share of each class of employee should be in producing the desired results and to reward accordingly—a decision which, in its turn, must lead to the reward of individuals in each class in proportion to the individual results obtained by workmen, foremen, superintendents, salesmen and managers, together with a greater confidence on the part of both employers and employed in the intrinsic justice of the movement itself."

A comparatively recent development of the profit-sharing ideal is in operation in Louisville, Ky., where, in addition to paying employees as good compensation as would be paid for the same class of work in any other industry, all workers receive a division of the total net profits, 50 per cent being placed to the credit of the regular surplus or reserve fund from which dividends for the stockholders are declared, while the remaining 50 per cent is divided in three equal parts: One-third being allotted to the executives, one-third to the manufacturing and recording division and one-third to the sales division. In distributing the allotment to the workers and clerical force, the weekly or monthly wage of the individual is used as a basis for calculation, the assumption being that a man who is paid a weekly wage of $25 is of more value than the man who received $18 a week, and, therefore, is entitled to a proportionately greater share in the profits. This is, perhaps, one of the simplest and most generous forms of profit-sharing reported. From this 50 per cent participation plan the rate of distribution ranges down to about 2 per cent of the earnings of the employee.

The Rockefeller plan for the maintenance of industrial peace developed as the result of the serious labor troubles which were encountered by the Colorado Fuel and Iron Company, in 1913. To prevent a repetition of these disturbances, John D. Rockefeller, Jr., representing the Rockefeller interests, the largest stockholders in the company, visited the mines, quarries, steel works, timber properties and other activities of the corporation, and, after familiarizing himself with actual conditions, with the assistance of the company's sociological department, drafted a plan for a form of industrial democracy that has operated so successfully that a similar system of workers' representation was provided for the employees of the Standard Oil Company, in March 1918. The unique feature of the Rockefeller plan is that it provides the machinery through which grievances and suggestions as to working conditions may be brought to the attention of the proper executives. While this is a matter that can more easily be arranged in smaller concerns, it represents one of the most serious problems with which large corporations have to deal, and Mr. Rockefeller is the authority for the statement that this method of meeting this difficulty has operated satisfactorily to the operatives as well as to the officers of the company. Under this plan, employees are given representation through delegates elected by secret ballot, and these representatives are not only empowered to settle with the officers of the company any grievances which may arise from time to time, but also participate in the regulation of all matter of welfare through joint committees on industrial co-operation and conciliation; safety and accidents; sanitation, health and housing, recreation and education. Regular district conferences between the employees' representatives and the company's officers are held, and it is guaranteed that, on these occasions, all matters of concern to the workers shall be discussed. The plan provides elaborate machinery by which the rights of an employee who has a grievance may be properly safeguarded, means being arranged through which disputes that cannot be settled otherwise may be taken as far as the president of the company, if necessary. The discharge of employees is also arranged under agreement with the employees' representative and can be only for causes previously agreed upon and posted where each worker may become familiar with the conditions. These include:

(1) Violation of the law; (2) Violation of prescribed safety rules and regulations; (3) Insubordination or use of profane or abusive language; (4) Absence from duty without notice except for sickness or other causes beyond the operative's control; (5) Harboring disease that may endanger the health of others; (6) Changing working places without orders or prowling around the works from assigned places; (7) Falsifying or refusing to testify in investigations of accidents or for false statements at time of application or physical examination; (8) Neglect or carelessness resulting in damage to railroad equipment; (9) Robbing railroad journal boxes of waste; (10) Wilful neglect in care or use of company's property; (11) Obtaining material on fraudulent orders.

The results of the operations of this plan are reported by Mr. Rockefeller (in 1918) to be as follows:

(1) Uninterrupted operation of plants and increased output; (2) Improved working and living conditions; (3) Frequent and close contact between employees and officers; (4) Elimination of grievances as a disturbing factor; (5) Good-will developed to a high degree; (6) The creation of a community spirit.

Mr. Rockefeller also declares that the "representatives of the men in the camps and mills have assured me that all grievances have been adjusted to the satisfaction of the employees, are in process of adjustment or the employees have been convinced that their grievances were not well founded. The representatives have expressed their own unqualified endorsement, approval and appreciation of the plan, which attitude, they say, is that very generally of the rank and file of the men, who constantly value the plan more highly as they understand its working better."

The application of this plan of co-operation to the Eagle (New Jersey) works of the Standard Oil Company occurred in 1918. At an election held on 27 March, 14 delegates were elected to represent the employees and the first meeting between these representatives and the officers of the company was held on 1 April. At the election, 92.2 per cent of the total number of wage-earners voted.

As in the West, the operation of the plan in Bayonne, N. J., is supposed to guarantee to each worker full justice and protection in all his rights. Future wage adjustments will be made in joint conference between the representatives of the workers and the company's officials, while discharges and suspensions are permitted only under similar conditions as those which exist in the Colorado Fuel and Iron Company, and any employee who feels that he has been unjustly treated or who thinks he is subjected to unfair conditions may through his elected representative appeal to the general

superintendent, or even to higher officials of the company.

The so-called profit-sharing plan of the Ford plants has been in operation since 12 Jan. 1914 and has proved successful, not only by increasing the stability of the working forces but also by bringing about a marked improvement in the morale of the organization. At the time this plan was adopted, it was widely announced that Henry Ford had established a minimum wage of $5 per day, but this statement was not strictly true as participation in the new rate of wage was confined to those who, in the opinion of Mr. Ford, were capable of using it "within limitations." The actual minimum wage, at the beginning of 1914, was fixed at 34 cents per hour. To those who could comply with the conditions imposed by the Ford plan, additional remuneration in the form of a share of profits was paid, the minimum share of 28½ cents per hour bringing the minimum earnings to 62½ cents per hour, or the widely-advertised $5 per day. The employees considered as possible participants in the profit sharing were classified in three groups: 1. All married men living with and taking good care of their families. 2. All single men, over 22, of proven thrifty habits. 3. Men under 22 years of age, and women, who were the sole support of some next of kin or blood relative. These restrictions were established because, as John R. Lee, one of the executives of the Ford Company, has stated: "it was clearly foreseen that $5 a day in the hands of some men would work a tremendous handicap along the path of rectitude and right living and would make of them a menace to society. So it was established at start that no man was to receive the money who could not use it advisedly and conservatively; also, that when a man seemed to qualify under the plan and later developed weaknesses that it was within the province of the company to take away his share of the profits until such time as he could rehabilitate himself."

To assure each operative just treatment under the new wage scheme, a large corps of specially trained investigators was employed to carry out the follow-up work upon which continuance in the profit sharing necessarily depended, and so successfully has the plan operated that, by the spring of 1916, about 90 per cent of the entire force were receiving their share of the profits. This naturally means that there has been a great improvement in the personnel of the organization. Thrifty habits have been developed; intemperance has largely ceased to be a considerable factor; domestic conditions have materially improved, while the increase in physical attributes is shown, not only in the reduction of the number of absentees but also in the productive achievements of the workers.

The concern that has most recently adopted a plan designed to afford employees a share in management is the Bethlehem Steel Corporation, and the idea is to be put in operation in all of the subsidiary companies, including several of the large shipbuilding corporations of this country. The principles of representation adopted by the company will, it is hoped, give all employees a voice in regard to the conditions under which they labor and provide an orderly and expeditious procedure for the prevention and adjustment of any future differences, as well as to anticipate the problem of continuous employment.

The plan provides that employee's representation shall be on the following basis: Plants employing under 1,500 persons, one representative for each 100 employees; where 1,500 to 10,000 persons are employed, one representative for each 200 employees; when plants employ more than 10,000 persons, one representative to each 300 employees. Representatives are elected for a term of one year and shall be deemed to have vacated office upon severing connections with the company. Any employee who has been on the payroll for not less than six months, who has reached his majority and is either an American citizen or has secured first papers is entitled for election as representative, while employment by the company for 60 days gives an operative the right to vote on questions of representation. The company appoints a management's representative whose duty it is to keep the management in touch with the representatives.

As in the Standard Oil plan, most of the detailed work of the organization is performed through various committees, which include: Rules; Ways and Means; Safety and Accident Prevention; Practice, Methods and Economy; Employees' Transportation; Wages, Piece Work, Bonus and Tonnage Schedules; Employment and Working Conditions; Health and Works Sanitation; Education and Publications; Pensions and Relief; Athletics and Recreation, and Continuous Employment and Condition of Industry.

The company by agreement guarantees that a representative shall be free to discharge his duties in an independent manner, without fear that his standing with the management will be affected by any action taken by him in his official capacity, and, to assure such independence of action, he is given permission to take a question of alleged discrimination against him on this account to any superior officer, to the president of the company, and, failing relief, to the State Department of Labor or to the secretary of labor of the United States.

Grievances which may occur in the future are to be handled by means of the machinery provided for this purpose. For example, where an employee is unable to adjust any matter with the foreman of the works where he is employed, it may be taken, either by the employee himself or, if he prefers, by his representative: (1) to the superintendent of the department; (2) with the management's representative, and (3) with one of the superior officers of the company, who will endeavor to effect a settlement, or who may, with the approval of all parties concerned, refer the question to the proper joint committee, consisting of the committee of employees' representatives with the addition of the same number of company's representatives, named by the management. If this method fails to effect adjustment within a reasonable time, the matter may be referred to the general joint committee on appeals, and if this settlement proves unsatisfactory, the president of the company shall be notified, and the question in dispute may thus be referred to an arbitrator, or arbitrators, to be determined by the nature of the controversy.

Another experiment in industrial peace through democracy in management was started in the Middle West in June 1914, and, as reported by the United States Department of Labor, the plan has proved so effective that all such questions as wage bargaining, hours of labor, discipline, discharges and adjustment of all grievances have now been put upon a collective basis.

Under this plan, all phases of management in which the employees are directly interested are handled through three separate bodies, known respectively as the senate, the cabinet and the house of representatives. The senate and cabinet represent the interests of the firm, while the members of the house of representatives are elected from among those employees of the company who have been in continuous service for at least six months, the election being by popular vote, in the ratio of one representative for every 15 employees, with the exception that a department having less than 15 operatives is given a representative.

Both the senate and the house of representatives have the power to initiate a proposition that is of interest to the employees, and may discuss and act upon all matters affecting their welfare. In case of disagreement in the actions of these two bodies, the matter is referred to a joint conference committee composed of an equal number of members from each body, and the results of their deliberations are finally submitted to the cabinet — composed of members of the executive board of the firm — for approval.

Much of the detailed business of the industrial congress is transacted by joint standing committees, including the betterment committee, which hears all complaints and adjusts grievances, the welfare committee, which deals with questions affecting the health and comfort of the workers, and the wage committee, the functions of which are: (1) To recommend and pass upon general changes in wages; (2) to suggest and pass upon minimum and maximum rates to be paid for the various operations according to skill involved, length of service and steadiness in attendance; (3) to sit with the planning board of the company for the purpose of passing upon individual increases in wages, and (4) to receive complaints of individuals to whom increases were denied. See ARBITRATION, INDUSTRIAL; PROFIT SHARING.

JOHN R. MEADER.

INDUSTRIAL RELATIONS COMMISSION. A commission created by act of Congress 23 Aug. 1912, for the purpose of inquiring into the general condition of labor in the principal industries of the United States, including agriculture, and especially in those industries which are carried on in corporate forms; into existing relations between employers and employees; into the effect of industrial conditions on public welfare and into the rights and powers of the community to deal therewith; into conditions of sanitation and safety of employees; into the growth of associations of employers and of wage earners; into the extent and result of methods of collective bargaining; into any methods which have been tried in any state or in foreign countries for maintaining mutually satisfactory relations between employees and employers; into the methods of mediation and conciliation; into the scope, methods and resources of existing bureaus of labor, and into possible ways of increasing their usefulness; into the question of smuggling or other illegal entry of Asiatics into the United States or its insular possessions, and of the methods by which such Asiatics are gaining admission, and to report to Congress recommendations for remedying existing difficulties. The commission consisted of nine members, including three employers of labor, three representatives of labor organizations and three representatives of the public at large. It separated its work into two large division: (1) public hearings; (2) research and investigations; and published valuable reports. Its final report was presented at the first session of the 64th Congress. It expired in August 1915.

INDUSTRIAL REPUBLIC. See INDUSTRIAL PEACE, EXPERIMENTS IN.

INDUSTRIAL REVOLUTION, The. Down to the middle of the 18th century few mechanical invention had been made and people were still using the appliances in use at the time of the Pharaohs. The people of western Europe continued to till their fields with crude implements, harvest their grain with a sickle and thresh it with a flail, weave their cloth on hand looms, and saw and plane their boards by hand as their forefathers had done for 3,000 years. Means of transportation and communication had shown similar stagnation. As an illustration of the backwardness of invention we may take the textile industry, which was carried on in every home. From the days of Penelope in the time of Homer down to 1760 only three improvements had been made in the method of making cloth, and only one of these introduced any considerable change. The first was in the process of fulling the cloth: instead of throwing it into a brook and having it trod into the mud by the bare feet of children it was now fulled by means of a water fuller run by water power. A second really significant change was made in the 15th century. It was the substitution of the spinning wheel for the distaff and spindle; but while the spinner could spin much more rapidly, she was still unable to spin more than one thread at a time. The third change was the "fly-shuttle," invented by John Kay in 1738, by which the weaver could manipulate his loom more rapidly and easily.

Industrial Revolution in England.— Suddenly, however, a series of inventions was made in England, beginning about 1760, which completely revolutionized the existing methods of industry and introduced a new industrial era. Greater and more far-reaching mechanical changes occurred in the next few decades than in all the world's history before. Machinery was substituted for hand tools, the factory system supplanted the domestic system of home works, and industry gradually assumed the shape that is familiar to us. This series of changes is known as the Industrial Revolution, a name first applied by Arnold Toynbee about 1880, but which is now in general use.

Just why the Industrial Revolution should have occurred at the time when it did, or why it should have taken place in England rather than on the Continent, are difficult questions to answer. Necessity seems to have preceded invention in this case as generally, for the need of improved mechanical appliances was keenly felt in England, France, Germany, Switzerland and other countries, and considerable progress had been made in the physical and chemical sciences. England took the lead in industry for several reasons. In the first place she possessed the most important raw materials either at home (wool, coal and iron) or in her colonies (sugar, iron, cotton, dye and other woods). All of these were of such a character that they could best be worked up in quantity; there was therefore a demand for machinery for this purpose in England. Her insular position and the consequent ease of waterway communication — which was the quickest and cheapest — gave her command of larger markets than any of the continental countries. The political situation in England was such as to ensure domestic tranquillity and the security of property rights, which were essential to the development of manufactures. In this connection might be mentioned also the breaking down of the restraints of the guild system and the development of a good system of patent law. Capital was already accumulating in England, much of it won from the colonies by trade, there was a sufficient supply of skilled labor, and under the domestic system there had grown up a class of middlemen or enterprisers who could conduct business on a large scale. The conditions were ripe in England for a rapid industrial development, and when a series of technical improvements was made after the middle of the 18th century, adjustments in organization quickly followed.

The first important inventions occurred in the textile industry. Under the domestic system, where the processes of spinning and weaving were both carried on by hand, a principal difficulty had been to provide enough yarn, as it required the work of from 5 to 10 spinners, each spinning a single thread, to keep one weaver occupied. In 1767 James Hargreaves invented a machine known as the jenny, which operated eight spindles instead of one; this number was later raised to 80. The following year Richard Arkwright patented a machine in which the threads passed through two sets of rollers, of which the second pair was driven at a higher speed and thus drew out the wool or cotton into thread. This roller machine was known as the water frame because it was operated by water power. It had, however, one drawback, in that it did not twist the fibre tightly enough to make fine thread. But this difficulty was met in 1779 by Samuel Crompton, who combined the best features of the two earlier machines into one, which because of its hybrid origin was named the "mule." As a result of these improvements in spinning machinery the traditional relations between the spinners and the weavers was reversed and more yarn could be produced than the hand looms could weave into cloth. In 1784 Dr. Edward Cartwright turned his attention to the construction of a power loom, which he succeeded in perfecting some three years later. Other improvements were made in the processes of printing and bleaching the cloth, but it remained for an American, Eli Whitney, to complete the series of improvements by his invention of the cotton gin in 1792. Whereas only a pound of cotton could be cleaned of its seeds in a day by hand, with the aid of the gin a man could clean 300. Unlimited cheap raw material was thus assured cotton manufacturers. The effects of these inventions upon the textile industry were revolutionary.

But in order that the new inventions might be made serviceable and machinery utilized to the utmost, it was necessary that it be driven by some non-human power. Indeed it cannot be too strongly emphasized that the vital feature in the Industrial Revolution lay in the substitution of power for human muscles. As long as man was confined to the use of hand tools his powers of production were strictly limited by the number of human hands available for this purpose, but as soon as machinery was invented and was driven by non-human power, there was no limit placed upon his powers of production through physical limitations. It depended now upon his ability to make the machines and to develop the power. Windmills were well known, but were unsatisfactory for this purpose, and at first water power was resorted to. But not until the steam engine was perfected did man have a really efficient instrument for this purpose. With this invention mankind entered upon an entirely new phase of development, and one that opens new vistas for the future.

The expansive power of steam was known to the ancient Greeks, but not until the 18th century was it put to practical use. In 1705 Newcomen constructed a practicable engine for pumping water out of the mines, and it was while repairing one of these crude affairs that James Watt in 1769 invented the improvements that made it a modern machine. It was now made adaptable for driving spinning machines, power looms and other mechanical devices. Its first use, however, was for pumping water, which had previously been a great menace, out of the coal mines, and hoisting the coal to the surface. This gave a great impetus to coal mining, which was further hastened by the invention of the safety lamp. The art of smelting iron by coal was made available about 1750, and in 1784 Corte discovered the process of "puddling." Other improvements were made in the blast, the substitution of rollers for the hammer, and in appliances for handling heavy castings. These changes reacted powerfully on the iron industry and the manufacture of machinery, as the new processes made iron stronger and at the same time more malleable and easily worked up. There was now no limit to the supply of strong and powerful machines, for which the demand seemed unceasing.

Results.— The effects of the Industrial Revolution were momentous and far-reaching, and resulted in a veritable social revolution. The most striking result was the great increase of productive power of a society equipped with these new appliances. Unfortunately, however, the benefits of this increase in output and wealth were very unequally distributed; the landlord and the capitalist class profited greatly, but the mass of the wage-earners gained little if any by the new inventions. Indeed for a while it seemed as if they suffered only loss, for the use of machinery permitted the use of the labor of women and children on a large scale and rendered valueless the painfully

acquired skill of the former hand workers. A second result was the destruction of the domestic system of production and the substitution therefor of the factory system. Under the former system industry had been carried on within the home by the domestic artisan, who generally owned his tools. Now, however, the new machines were much too expensive to be owned by a cottage workman, and it was moreover impossible to operate them in the home, as they were driven by power. It became necessary to bring both machines and workmen together in factories, where the building, the machinery and the materials were owned by the capitalist enterprisers. This brought about a sharp distinction between the two classes of workers involved, the capitalists on the one hand and the wage-workers on the other. Due to the need of capital in order to undertake manufacturing under the new conditions, the worker became more dependent upon the capitalist for employment. These facts brought to the front questions of labor and capital, which have become increasingly important as time has passed. See FACTORY SYSTEM.

Industrial Revolution in the United States. — The term Industrial Revolution has usually been applied to the sudden and remarkable series of changes that occurred in industry in England between 1760 and 1790, though it took another generation for them to work themselves out. The old domestic system of industry was completely transformed and a revolution wrought in the economic and social life of the people. It is interesting to raise the question whether other countries have experienced similar changes and whether we can apply the term to other periods than that just mentioned. The nearest approach to an industrial revolution in the United States probably occurred in the 30-year period beginning with 1808, when a series of political and industrial events led the people to develop manufacturing by the factory system in addition to agriculture and commerce. This did not lead to any revolutionary changes as in England, since there had never been any widespread development of the domestic system of manufactures before this time. The transfer from one system to the other was therefore accomplished without any painful readjustment or suffering. A similar industrial transformation from agricultural to manufacturing conditions occurred in France between about 1820 and 1850, and in Germany after 1870.

Conclusion.— It is unlikely that we shall again have such a sudden and complete revolution in industry as occurred in England at the end of the 18th century. And the reason is not because of the absence of change, but rather because change is a normal condition of modern industry. Manufacturers to-day expect new inventions and take into account the obsolescence of their machinery as naturally as they do its depreciation. Change is constant but just on that account it is less felt than was the Industrial Revolution, because there is constant adjustment. New inventions or changes in transportation or other factors may and often do completely revolutionize a business within a decade. but such changes are now regarded as a condition of progress. Being anticipated, they are met and bring no train of disasters such as made the English Industrial Revolution famous in history. See GREAT BRITAIN — INDUSTRIAL REVOLUTION; HISTORY, MODERN.

INDUSTRIAL SCHOOLS, an English term variously applied; sometimes synonymous with the so-called Ragged Schools, in which mechanical arts are taught; sometimes designating ordinary elementary schools in which agriculture, domestic science or some other industrial art is taught during a portion of the school day. The term is becoming obsolete, having fallen into disfavor because of its application to reformatories.

INDUSTRIAL SERVICE. See INDUSTRIES, WELFARE WORK IN.

INDUSTRIAL TERMS. The following list embraces many of the important terms that are used technically in the several commercial industries. Such terms as are usually regarded as self-explanatory, as well as those that have no general application, have been omitted. Those that are of more than ordinary importance will be found defined more fully under their appropriate heading.

ABB.— In wool-sorting the quality of the wool is denoted by the terms: "fine abb," and "coarse abb."

ACIERAGE.— In engraving, the deposition of a very thin layer of steel on the face of an engraved copper plate, to increase its durability under the stress of printing.

ANNEALING.— The process of treating substances by heat to remove their brittleness and yet make them tough and inclined to be elastic.

ANTHICHLOR.— A term used in bleaching to denote the method employed to remove or neutralize the injurious effects of the free chlorine left in some bleached materials.

ARCH.— When a portion of a lode is left standing, in mining, because it is too poor to work or is needed as a support, it is called an "arch."

ASHLARING.— In carpentry, the placing of upright studs to form vertical walls of a room constructed under the slopes of a peaked roof.

ASTERISM.—A term in printing denoting the three asterisks sometimes placed before a sentence to call attention to it.

ATTEMPERATION.— Regulating the temperature of the beer-worts in brewing.

ATTENUATION.— The decrease in density of the beer-worts in brewing is termed "attenuation."

AUTOGENOUS SOLDERING.— Joining pieces of the same metal by fusing them together by a melting heat applied at the juncture.

AVIVAGE.— A process for clearing and brightening the colors in dyeing.

BACK.— (a) In metal-mining, the portion of the lode that lies between the level and the one next above it; (b) in coal-mining, the inner end of a heading where work is being conducted; (c) the thickest and best hides are termed "backs" in the leather trade.

BACK-CASING.— A wall of dry brick sunken through sand or gravel in mining.

BACKLASH.— In coal-mining, the backward suction after an explosion of firedamp.

BACK-STAY.— In printing, the leather strap used to check the carriage of the press; in lathes, a support to prevent the work from springing away from the cutting tool.

BALK.— When a bed of coal suddenly thins out it is termed a "balk."

BALLOONING.— In spinning, the bellying outward of the thread while it is being wound on the bobbin.

BAND.— A layer of rock that is interstratified with coal.

BARNEY.— A small car used in mining to push the mine-car up a slope; the pit from which it runs is termed the "barney-pit."

BARREL-WORK.— Pieces of native copper too small to be handled as mass-copper, but large enough to be shipped in barrels.

BASTARD.— (a) An impure brown sugar made from the refuse of previous boilings; (b) the large mold into which the sugar is drained is also called a "bastard;" (c) in printing, any type whose face is out of proportion to the size of its body is termed "bastard" type.

BASTARD FLATTING.— In painting, the "egg-shell" semi-gloss surface produced by using three times as much turpentine as oil in the paint mixing.

BATING.— The process of steeping hides and skins to render them soft and fit for tanning.

BATTERY.— The timber structure that is used to prevent coal from sliding down a shute.

BAY.— In mining, an open space for waste in a long-wall working.

BEAMING.— (a) Winding the warp-yarn on a loom in the manufacture of cloth; (b) working hides with a slicker over a beam in the leather trade.

BEATER.— (a) A machine used in cotton manufacturing to open and clean the cotton before it passes to the carder; (b) a knife used for breaking flax or hemp; (c) the batten of the loom used for weaving.

BEAUMONTAGE.— The filling material used to stop small holes in wood or metal work; in the first instance made of varnish thickened with chalk and resin, in the case of iron, with a mixture of iron filings and sal ammoniac.

BENCHING.— A term applied to the process used in getting the coal after it is holed.

BLACK-LIQUOR.— A crude acetate of iron used, in dyeing, as a mordant.

BLEED.— (a) In bookbinding, to trim the margin too closely; (b) in dyeing, extracting the coloring matter.

BLEU-DE-ROI.— The term used to denote the cobalt-blue color in European porcelain.

BLICK.— The iridescence appearing on gold and silver at the end of the refining process.

BLOOMING.— Clouding of a varnished surface usually through the absorption of moisture.

BLUE-CAP.— In mining, the bluish or brownish halo which, when it appears around the flame of the safety lamp, indicates a dangerous quantity of fire-damp, is termed the "blue-cap."

BOARDS.— The hard paper-stock inserted between the printed sheets in a press to remove an indentation of impression; often called "press-boards."

BONE.— The term used to define the slaty portions in a coal mine.

BONNET.— The shield used to protect a mine shaft from substance which might otherwise fall into it.

BORDER.— The rim fixed about the bed-plate used in milling to prevent the meal from falling off before it reaches the proper opening.

BOSSING.— The working of lead sheets into hollow forms by pressure, without cutting and soldering.

BOX CALF.— Chrome-tanned calf-skins, which bear square markings due to rolling the skins lengthwise and from side to side while still damp.

BOXING IN.— In printing, the enclosing of special reading matter with a frame of rule.

BRANNING.— A term that is applied both to the process of steeping cloth before or after it is dyed, and to the steeping of skins before tanning.

BROOD.— The term applied in mining to all heterogeneous mixtures found with copper or tin ore.

BRUSH.— An instrument constructed of several small trees, like the birch, and used by farmers instead of a harrow in covering grain, or small seed after sowing.

BUCK.— The breaking of ore into small pieces for jigging.

BUDDLE.— In mining, to wash ore free from earthy matter the water is run over an inclined hutch which is termed a "buddle."

BULLING-BAR.— In mining, the bar used to ram clay fillings into open cracks before blasting.

BULLY-HEAD.—The name by which the sledge-hammer used by miners is popularly known.

BULTOW.— In the fishing industry, the practice of stringing many hooks on one line, used in fishing for cod off the Banks.

BUNCHY.— Used in mining to denote that the ore is irregularly distributed through the lode in small masses, or "pockets."

BUNDLE.— (a) In paper-making, 2 reams of printing, or brown paper; (b) in spinning, 20 hanks, or 6,000 yards of linen yarn.

BUNTONS.— The timbers put across a mining shaft to divide it into compartments.

BUTT.— A hide of sole leather in which the belly and shoulders have been cut off.

CADE.— A term of measurement in the fishing trade, denoting either 500 herrings, or 1,000 sprats.

CAGE-SEAT.— The framework at the bottom of a shaft, so arranged as to reduce the jar when the cage drops upon it.

CALF.— A term applied to a bookbinding in calf-skin. This binding is of several grades: Divinity calf, a dark-brown binding, with blind stamping and no gilding; half-calf, in which the backs and corners only are of calf-skin; mottled calf, a calf binding of pale color in which the decorations have been made by the sprinkling of acid; smooth calf, or plain, undecorative leather; tree calf, a bright, brown calf binding stained by acid to imitate the trunk and branches of a tree.

CAMBER.— In building, the amount of curvature upward given a horizontal beam; for cast iron ¼ inch for each 10 feet of span; for steel, ⅛ inch for the same span.

CANCELS.— In printing, the pages of a book which have been reprinted because of error in copy or type. They are marked usually by an asterisk in the bottom margin of the page.

CANCH.— A term used to denote that part of a floor or roof of a gangway that is removed to equalize the grade because of a fault, or break in the strata.

CANT BRICK.— A brick cut at any angle other than a right angle.

CANNEL.— A form of weaving that produces a corded or rep tissue.

CAP.— A term denoting certain sizes and shapes in paper: Double cap, 17 x 28 inches; exchange cap, a fine quality paper, used in printing bills of exchange; flat cap, or full cap, 14 x 17 inches; foolscap, usually 12 x 15 inches; legal, or pot cap, 13 x 16 inches, etc.

CARCASE.— In building, the rough structure of a building (or a ship) before finishing work is begun.

CARDING.— The disentangling of wool, cotton or other fibres with a card, preparatory to spinning. See COMBING.

CARRIAGE.— In building, the inclined timber structure which supports the staircase.

CARROT.— In the fur trade, to dress a pelt to preserve it from insects.

CARROTS.— Rolls of tobacco after they have been so prepared that they require only to be ground and sifted to be made into snuff.

CASE.— (a) A shallow wooden tray, the partitions making the small boxes in which the various characters of type required by printers are kept in order for the use of compositors. (b) A book cover that has been made separately from the book for which it is intended.

CASE-HARDENING.— Producing a thin surface layer of steel upon soft iron articles by heating them to cherry-redness in contact with charcoal or other carbon.

CASSE-PAPER.— The wrinkled, broken, or otherwise imperfect paper rejected by the trade.

CASSETTE.— The utensil in which chinaware is baked; sometimes called the "coffin."

CAST.— (a) The water used in the preparation of beer. The quantity that is first placed in the mash-tub is termed the "first cast;" that which is subsequently added, the "second cast," "third cast," etc. (b) In bee culture, an after swarm led by a maiden queen.

CATCHWORD.— In printing, the setting of the first word of the following page at the lower right-hand corner of the page form — found only in old books.

CATGUT.— Strips cut from the specially treated intestines of sheep and horses.

CERTOSINA WORK.— A term used to denote the inlay of certain light materials — like ivory or satinwood — upon dark woods like walnut.

CHASE.— In printing, a square, open framework of iron into which the type forms are fastened to facilitate moving and working on the press.

CHASE MORTISE.— In building, a mortise with one side on a bevel to allow the easier entrance of the tenon.

CHEMICAL PULP.— Wood pulp in which the fibres have been separated by chemical process instead of by mechanical means.

CHILLED CASTINGS.— Iron castings with hardened surface produced by casting in metal molds which conduct away quickly the heat of the molten iron.

CHOP.— (a) In milling the product of the first crushing of the wheat; (b) also used to denote the brand and quality of tea imported from China, as "first chop," etc.

CHROME LEATHER.— Leather tanned with chromium salts instead of vegetable tanning agents.

CISSING.— In painting, the appearance of small dull spots in a varnished surface due to underlying oil or grease.

CLEARCOLE.— A coating of glue size and chalk laid upon plaster walls before painting them.

CLICKER.— The workman who cuts the uppers and soles for boots and shoes.

CLOG.— The short pieces of timber used in mines to prop the roof.

CLOSING-MACHINE.— (a) A machine that sews heavy cloth or leather with a lockstitch, alike on both sides; (b) apparatus used in rope-making to twist the already made strands into rope.

COBBING.— In mining, a process of breaking the ore that the better parts may be sorted out.

COCKLE.— (a) A large stove used in the making of porcelain, to dry the biscuit-ware after its glazing preparatory to burning; (b) the kiln used for drying hops.

COLD BEND.— In iron specifications, the angle at which iron bars or plates break when bent cold.

COLOR.— (a) In gold mining, the particles of gold that are shown when auriferous sand is washed out; (b) in printing, the evenness of distribution of ink in an impression.

COMBING.— In spinning, the removal of short fibres from the carded textile before it is spun.

COMMERCIAL.— A term used to denote the shape and size of paper: Commercial letter, 11 x 17 inches; unfolded commercial letter, small, 10½ x 16½ inches; commercial note, 8 x 10 inches, unfolded.

COMPANIONSHIP.— In printing, a number of compositors employed in setting up a quantity of copy under the direction of one leader.

COMPOST.— A mixture of various manuring substances used by agriculturists in fertilizing land.

CONCENTRATOR.— A machine used, chiefly in mining in the United States, to separate the ore from the rock with which it was associated in the lode.

CONDITIONING.— In spinning, the dampening of cotton fibre to restore its natural percentage of moisture before spinning.

COP.— The cylindrical form in which cotton yarn is built up when spun on the mule. There are three sizes: Pin cop, bastard cop and twist cop. Woolen cop is of conical form.

CORD.— (a) In fancy weaving, the interval between two vertical lines of the design is termed a "cord;" (b) the same term is used in bookbinding when a book is tied firmly between two boards to assure its drying smoothly. The term "Maitland cord" is used in weaving to denote the cord which extends along the wooden shafts of leaves to which the heddles are secured.

CORDING.— The term denoting the arrangement of the treadles in a loom by which they are made to move in such clusters and time as the production of the pattern may necessitate.

CORE-PIECE.— The yarn running through the centre of a rope to assure its solidity.

CORNER.— The triangular tool used in bookbinding to decorate the corners of a book.

COUCH.— (a) The operation, in brewing, of spreading the steeped grain upon the floor to convert it into malt; (b) in paper-making, the act of removing the paper from the mold upon which it has been formed that it may be placed upon the felt.

COUCH ROLL.— In paper making, a felt-covered roll which squeezes out the surplus water from the sheet of wet pulp as it leaves the wire.

COUNTER-LODE.— A term used in mining to denote a lode running in such a direction in relation to the main lodes that it crosses or intersects them.

COUNTS.— In spinning, the relative diameter of threads, as measured by the weight of a stated length. Single thread counts in cotton are the number of hanks of 840 yards in 1 pound: That is, a 20-cotton thread is 20 hanks to the pound. In worsted, the basis is 560 hanks to the pound. In wool, it is the number of one-yard skeins in 1 dram.

COURSING.— The method of regulating the ventilation of a mine by conducting the air through various doors, stopings, etc.

CRABBING.— In woolen manufacture, a treatment of the cloth with live steam through a perforated roll; the object being to prevent subsequent wrinkling.

CRADLE.— (a) A movable hanging scaffold used by painters and builders, supported from above, and operated by ropes and pulleys; (b) in mining, a rocking tray for washing out placer gold.

CRAM.— In weaving, a warp that has more than two threads in each split of the reed.

CRAWLING.— In painting, the wrinkling of varnish, due to too heavy a coat or a sudden rise in temperature while the varnish is drying.

CRAZING.— In the pottery industry, when the glaze separates from the body and forms blisters.

CREASER.— A tool used in bookbinding to define the width of the bands of a book, and to fix the position of the lines on the backs and sides.

CREASING.— A course of tiles projecting on each side of a wall at the top, to prevent the soaking in of water falling upon it.

CREEP.— If the pillars of a mine are not sufficiently large, or the roof is not fully supported the pressure of the superincumbent strata sometimes causes a bulging or rising of the under-clay. Colleries have been entirely destroyed by "creep."

CREEPING.— The movement backward of a rubber tire when it is too loose on the rim.

CRIZZLING.— In glass manufacture, a blemish of the surface due to using cold tools upon it while in the plastic state.

CROP.— An untrimmed hide, struck for sole-leather, is termed a "crop," or "crop-hide" in the trade.

CROPPED.— In binding signifies that the margins of the pages have been trimmed too close.

CROPPING.— In cloth making, a machine process for shearing the nap of cloth.

CRUP BUTT.— In leather work, the oily part of a horsehide which covers the loin of animal, used especially for the uppers of hunting and fishing boots.

CRUTCH OR CRUTCHER.— A term used in soap-making to denote the perforated instrument with which the various ingredients are kept mixed while cooling.

CULLET.— In glass manufacture, clean waste and broken glass from previous meltings and castings added to a raw batch to initiate the fusion.

CURE.— In leather making, the substance used to prevent decomposition in raw hides and skins. The commonest cures are salt, arsenic, boracic acid and some of the coal-tar carbolic products.

CUT.— The block upon which a picture is engraved and from which it is impressed in printing.

CUTTER.— Usually applied, in mining, to a joint or crack which crosses a better defined system of cracks in the same rock.

DABBER.— The use of the "dabber" by printers has largely ceased since the introduction of the ink roller, but the same term is now applied to instruments used by etchers and stereotypers. The former is used to ink the surface of engraved blocks or plates; the latter to dab the back of the damp paper used in the papier-mache process of stereotyping, in order that it may be driven into the interstices of the type.

DABBING.— The term applied to the process in stone-working by which the surface of the stone is covered with small indentations, after having been made uniform.

DAM.— The term applied to the underground wall frequently constructed to hold back water, air or gas.

DAMPING.— A process used in bleaching to add a certain amount of moisture to a fabric, after it has been starched, that it may be properly finished.

DANDY.— The running-out fire for the melting of pig-iron in tin-plate manufacturing.

DANDY-ROLL.— The wire-gauze cylinder beneath which the web of water-pulp is passed in paper-making to drain it partially of water and impress the watermark.

DASH-POT.— A controlling device for checking sudden movements in mechanisms, consisting of a cylinder filled with oil or water in which moves a loosely fitted piston.

DASH-WHEEL.— The partially submerged wheel used in cotton manufacturing to wash and rinse calico in the piece.

DEAD GROUND.— In mining, those parts of the vein which do not contain ore.

DEAD MELTING.— In foundry practice, heating metal to a temperature considerably higher than its melting point.

DECK.— Used in mining to denote the loading or unloading of cars upon the cage.

DECKLE-STRAP.— The contrivance used in paper-making to define the width of the sheet by regulating the flow of pulp.

DELE.— A term used in proofreading to direct the compositor or printer to remove a letter, word or phrase.

DEMY.— A standard size in paper sheets. Printing demy is 22½ x 17½ inches; writing demy, 20 x 15½ inches; drawing demy, 22 x 17 inches.

DENTELLE.— In bookbinding, a style of finishing with delicate lace-like tracery in gilt.

DEPTH OF FOCUS.— The capacity of a lens (q. v.) to focus on one plane images of objects located at widely differing distances from the lens. This capacity is enhanced by the use of smaller stops.

DERBY FLOAT.— In plastering, a tool for smoothing freshly laid plaster. It consists of a longish board with a peg handle near each end. See FLOAT.

DEVIL.— (a) An errand-boy employed in a printing-office; (b) a plumber's fire-pot for heating solder and lead.

DIP CRANK.— A crank formed by bending a rod to crank form instead of building it up from separate pieces, or cutting it from a forging.

DIPPING.— A process in ceramics by which a coarse clay body is coated with fine enamel by being plunged into the liquid which constitutes the coating.

DISCHARGE.— In dyeing, the process by which white patterns are produced on colored grounds by a chemical bleaching or release of the color.

DISCOVERY CLAIM.— In mining law, the portion of ground held by reason of the first discovery of its mineral deposits.

DISHED.— The form given to wheels or discs where the centre is in a hollow as compared with the plane of the rim.

DISTRIBUTE.— A term used in printing for the process of returning dead matter (type no longer required) to the cases; "thrown-in" is another term used to define this process.

DOCTOR.— (a) A term in wine-making, used to indicate that the character of the wine has been changed by the addition of another liquor; (b) to alter any commodity for purpose of deception.

DOFF.— A term that has several distinctions in the textile manufacture: (a) The process of stripping the cotton or wool from the cards preparatory to spinning; (b) the act of mending broken threads; (c) the removal of full bobbins to give place to the empty ones.

DOLLY.— (a) A soft polishing mop rotated at high speed for putting the final surface on metal work to be plated; (b) in mining, a heavy tool, sometimes of wood for crushing soft materials.

DONGOLA.— As applied to leathers, skins which have been tanned by both the vegetable and mineral tanning agents successively.

DOSSIL.— The roll of cloth used to clean the ink from an engraved plate prior to printing.

DOUBLE.— A term used to denote the size and quality of paper: Double medium, a printing paper, 24 x 38 in.; double royal, a printing paper, 26 x 40 in.; double demy, 35 x 22½ in.; double imperial, 44 x 30 in.

DOUBLE-DYEING.— A method of dyeing mixed goods by which the wool and cotton are dyed separately with colors that have no affinity for the other fibre.

DOUBLE-MILLED.— A term applied to denote that cloth has been fulled twice to make it finer in quality.

DOUBLER.— (a) A machine for doubling and drawing silk; (b) a still made to intercept and redistil the vapors of distillation; (c) a felting placed between the fabric and the press before printing.

DOWNCAST.— A term used to denote the system of ventilation used in mining, the shaft down which the air passes into the mine being called the "down-cast."

DRAFT.— In weaving, a chart or plan showing the cording of a loom or the arrangement of the heddles.

DRAG.— (a) A light iron-rod tool with a tapering spiral end, used by miners in cleaning out bore-holes before introducing the blasting charge; (b) the device that guides wood to the saw in saw-milling; (c) also applied in printing to denote the thickened impression on one side of the letters produced by the scraping of the sheet on the type.

DRAW.— In cotton spinning, the extent of the outward and inward run of a mule carriage, usually 63 or 64 inches. The speed of the mule is designated by the number of draws per minute.

DRAWING-PAPER.— A term used commercially to describe a variety of stout papers manufactured expressly for use in drawing. The regular sizes are as follows: Cap, 13 x 16 in.; demy, 15½ x 18½ in.; medium, 18 x 22 in.; royal, 19 x 24 in.; superroyal, 19 x 27 in.; imperial, 21½ x 29 in.; elephant, 22½ x 27½ in.; columbier, 23 x 33½ in.; atlas, 26 x 33 in.; theorem, 28 x 34 in.; double elephant, 26 x 40 in.; antiquarian, 31 x 52 in.; emperor, 40 x 60 in., Uncle Sam, 48 x 120 in.

DRAWING ROLLS.— Rolls used in spinning machinery set in successive pairs, each of which turns more rapidly than any previous pair, the sliver (q.v.) passing through them in succession.

DRAW-BOY.— Formerly the weaver's assistant; now, a mechanical device used in drawing the heddles to form the pattern of the cloth to be woven. The machine upon which this figure-weaving is done is known as the "draw loom."

DRAWN.— A term denoting the method of freeing substances from all particles of iron and steel by use of a magnet.

DRESSER.— (a) The workman employed in type-foundries to remove all defects from the types in preparing them for sale; (b) the tool, or machine employed to cut and dress the furrows on a millstone; (c) a mallet used by plumbers for flattening sheet-lead; (d) one of the picks used in mining.

DRIFT.— A term used in mining to describe the nearly horizontal passage ways frequently excavated in working a mine; sometimes called a "drive."

DRILL.— (a) In agriculture, when a field is not sown broadcast, but in rows, it is said to be in "drills"; (b) also the machine for sewing in this way.

DRIFT-JOINT.— When two sheets of metal used in roofing have been joined without soldering by a step-down, so that the joint forms a water-conductor the arrangement is known as a "drip-joint."

DROP-BAR.— A term applied to the bar or roller on a printing-press that regulates the passage of the paper sheets to impression.

DROP-FINGER.— In some cylinder printing-presses the rods that are employed to hold the sheets in place until they can be seized by the grippers are termed the "drop-fingers."

DROPPER.— A term used in mining to denote a branch or spur that connects with the main lode but does not materially enrich it.

DROPPING.— A term used to denote a defect in the product of the glassmaker. It is caused by the accidental dropping of crude glass or furnace lining into the molten glass in the melting vessel.

DROP-ROLLER.— Used in printing to denote the roller that drops at specified intervals to supply the printing ink for distribution on the ink table.

DROVING AND STRIPING.— A process in stone-cutting by which the shallow parallel grooves are made along the length of the rough-hewn stone.

DRUNKEN SAW.— A "wobbling" circular saw, set off at right angle on its arbor, used for cutting a groove in timber, the width of the groove being governed by the aberrance from a right angle.

DRYING-OFF.— A term denoting the process by which an amalgam of gold is evaporated.

DRYING-PLATES.— Used in brewing to denote the series of frames in the malt kiln. They are placed one over the other, and, being covered with woven wire, the hot air ascends through them in such manner as to dry the malt.

DUMMY.— In plumbing, a wooden rod having a lump of lead at the end, used for ramming out dents in lead pipe.

DUMP.— Used in printing to denote the act of removing types from the stick to place them on a galley.

DUNG-BATH.— In some processes of dyeing and calico-printing the cloth is subjected to a "dung-bath," composed of warm water, animal's dung, etc., for the purpose of removing the superfluous mordant.

EASING.— In weaving gauze, the motion by which the tension of the warp is slackened during the formation of the cross-sheds.

EGG-SHELL.— A term used commercially to denote the thinnest and most translucent of china or porcelain.

EGG-SHELL FINISH.— See BASTARD FLATTING.

ELBOW-PLATE.— In paper-making, the cutter of the rag-cutting machine when bent to an angle in the middle.

ELECTROPLATING.— The process of coating articles with silver or other metal by means of electrolysis.

ELECTROTYPING.— The process of making plate copies of any engraved or molded surface by means of electrical deposition.

ENSILAGE.— An agricultural term used to denote the process of preserving fodder, etc., in a green state by storing the materials under pressure in silos or in pits dug in the ground.

ENTASIS.— The slight convexity in the upright outline of a pillar or column; more pronounced in Roman architecture than in Greek types.

FACE.— In coal-mining, the working, or portion of the seam that is being mined.

FASCET.— A rod, or basket of wire used in carrying the bottle from the mold to the leer in glass-manufacture.

FAT-COLOR.— Paint which has been long mixed and has become thickened and greasy.

FAT LIQUOR.— In leather manufacture, an emulsion of fish or other oils with soap, and, usually yolks of eggs, used as a dressing for skins.

FAT-WORK.— In printing, when copy is particularly profitable to the compositor owing to the fact that it has much open space that may be filled with quads, or that in other ways favors rapid execution, is termed fat-work. To beat, or ink "fat" in printing means that a form of type has been given an excess of ink.

FEEDING.— In printing, a term denoting the method of placing the sheets of paper in such position that they are ready to meet the requirements of the press.

FEINTS.— The first products of distillation which come over from a pot-still when making whisky.

FETTLING.— The operation of removing fins, etc., from castings.

FIGGING.— In soap making, a spotty appearance of the soap due to undissolved specks of potasium stearate; considered a mark of excellence. It is simulated by the addition to common soaps of flecks of clay or talc.

FILATURE.— In silk-culture, a reel by which the silk is drawn from the cocoons. Also used as to the quality of the raw silk marketed on these reels.

FILLET.— (a) In weaving, a strip of card-clothing; (b) in dairying, a perforated curb used to confine the cheese-curds; (c) a wheel-shaped tool used in bookbinding to impress a gilt line, or decoration upon the covers of books; (d) in printing, a rule fixed with lines that may be used as a border.

FILLING.— (a) The term by which the woof or weft thread of a woven fabric is known; (b) in soap making, the treatment through which the soap is made to carry an excess of water or other adulterant.

FILLING CAN.— In rope-making, the can in which the sliver is condensed and wound after coming from the doublers.

FINE-DRAWING.— The term applied to the finishing process in cloth manufacture. By exposing the cloth to a strong light all the minute holes due to breaks are discovered so that they may be repaired with a needle, by the introduction of sound yarns in the place of those that have proved defective.

FINING-ROLLER.— A cylindrical sieve of wire cloth used in paper-making to retain the coarse fibres and knots so that they cannot pass through with the finely ground stuff.

FIRE-GILDING.— A process of gilding by the application of an amalgam from which the mercury is afterward driven by the heat of a muffle, leaving a fine film of gold.

FIXING BATH.— (a) In tanning, the catechu-bath is followed by another known as the "fixing" bath. It consists of water sufficient to cover the skins, acidified with nitric acid, modified with a little glycerine; (b) in photography the chemical bath used to dissolve from an exposed plate the silver salts not changed by the action of light.

FLASHING.— (a) A strip of sheet lead, zinc, or copper used to make a watertight joint between a roof and the chimney passing through it, or in the valleys formed by angular intersections in a roof; (b) in glass manufacture, the laying upon glass of a thin coating of glass of another color.

FLATTING.— In painting, the laying of a coat of paint with a dead surface.

FLESHER.— The tool used in leather manufacture for the purpose of fleshing hides, that is, removing adhering flesh or fat.

FLIGHT.— The series of steps between a floor and a landing.
FLITCH.— The piece of wood or metal added to a beam to strengthen it. The beam is thence termed a flitched beam.
FLOAT.— (a) The flat metal tool used by masons for smoothing the surface of fresh plaster; (b) in weaving, the passage of the shuttle crosswise above or below the threads but without intersecting them.
FLONG.— The combination of moist tissue paper and paste used in stereotyping by the papier-mache process to form the mold or matrix from composed types or engraved surfaces.
FLOOR.— In brewing, each steeping is known as a "floor" or "piece."
FLOORING.— Used in brewing to denote the operation of spreading the grain on the malt-floor, that it may be kept at an even temperature, to check germination.
FLOW.— A term used in ceramics to denote the flux that is used to make the colors run and blend in firing.
FLUE WORK.— In pipe organs, those "stops" which produce their tones by the vibration of air columns, and not by reeds. They include the "principal," "flute," and "stopped" groups.
FLUFFING.— In leather manufacture, the process of smoothing a leather surface on an emery wheel.
FLURRY.— A term used in calico printing to denote the condition of frothiness which is sometimes developed by the colors during the process of printing.
FLY.— (a) One of the arms of a spinning-frame which revolves around the bobbin to twist the yarn as it is wound upon it; (b) in cotton and wool spinning, the term applied to the fibre collecting on the carding rolls: (c) in weaving, a shuttle with wheels driven through the shed by a jerk; (d) in printing, the mechanism which receives and delivers the separate sheets as they are printed on the press; (e) in piano-making, the hinged board with which the keys are covered when not in use; (f) in clocks, the fan which controls the speed of the striking train.
FLY-NUT.— A nut with wings by which it may be turned with the fingers.
FOLIO.— While the word "folio" is used to denote the size of a book it is also applied as a descriptive term for several sizes of paper, each of which is designated by a specific name: Pot folio, 7½ x 12½ in.; foolscap folio, about 8 x 12½in.; flat-cap folio, 8½ x 14 in.; crown or post folio, 9½ x 15 in.; demy folio, 10½ x 16 in.; medium folio, 12 x 19 in.; royal folio, 12½ x 20 in.; superroyal folio, 14 x 22 in.; imperial folio, 16 x 22 in.; elephant folio, 14 x 23 in.; atlas folio, 16½ x 26 in.; columbier folio, 17½ x 24 in.; double elephant folio, 20 x 27 in.; antiquarian folio, 26½ x 31 in.
FOOLSCAP.— A term applied to a writing paper varying in size from 12 x 15 to 12½ x 16 inches. The term was derived from the water-mark, a fool's cap, which formerly appeared upon all the papers that bore this name.
FOOTLINE.— A term used in printing to denote the last line of a page of type. It is usually left blank, although it sometimes contains the number of the page or the signature on the sheets.
FOOTS.— The impure residues left after the refining of oils, fats, waxes, and greases.
FORMAT.— In printing, the plan of the page form of a book; as folio, octavo, etc.
FORWARDER.— A term used in bookbinding to designate the workman whose duty it is to receive the sewed book, put on its back, cover, etc., and prepare it for the finisher.
FRIZING.— In leather manufacture, the removing of a very thin layer from the grain (hair) surface of a skin.
FULL-FACED.— A term used in printing to describe a type with the thick lines that make it print extremely black.
FURNITURE.— The term "furniture" in printing denotes the pieces of wood or metal that are placed around the pages of type, not only to keep them the necessary distance apart but to assist in fastening them securely in the chases. When the furniture has been systematically cut into various standard lengths and widths, so that they may be easily combined, the pieces are known as "labor-saving furniture."
FUSTAIN.— The term applied to a short twilled cotton fabric, usually a cloth having a short pile, like corduroy, velveteen, etc.
GAGING-THREAD.— In weaving, a thread introduced temporarily to stop the weft-thread at a specified point.
GALLEY.— An oblong, shallow tray, now usually made of brass, but sometimes of wood, used in printing by compositors as a place to deposit the type they have set. Galleys in which the type may be locked are known as proof-galleys. Standing galleys are inclined frames fitted with cleats on which the type galleys rest. A proof taken from types being held on galleys is termed a "galley-proof."
GASSING.— In textile manufacture, the process of singeing off loose fibres and fluff from thread by passing it through a gas flame.
GATHERING.— (a) In glass-making, the method of coiling the molten glass on the end of an iron tube preparatory to the work of blowing; (b) in book-binding, the collecting of the printed and folded sheets in their proper consecutive order.
GIGGERING.— A process in bookbinding by which the burnished lines are laid by a sliding or rubbing movement, upon covers decorated in antique fashion.
GIGGING.— The process of finishing cloth by drawing the loose ends of wool in a fabric to the surface to form a nap. After the work of napping is completed the fabric is ready to be finished by shearing.
GILLING.— A term denoting a process for making all fibres level and even in the manufacture of woolen yarns or worsted.
GINGERBREAD-WORK.— A phrase used, somewhat as a term of contempt, in describing the fanciful shapes of the ornate wood-work and carvings seen in the ornamentation of houses, furniture, etc.
GLAIR.— In book-binding, a foundation applied where gilding is to be laid, made of whipped white of egg and a very little vinegar.
GLANCE.— A term used in mining to designate those ores in which a peculiar lustre and color indicates that they are of metalliferous combination.
GLORY HOLE.— A small furnance used to reheat glass in process of manufacture.
GLOSSING.— A term denoting the operation of twisting the hanks of silk, in silk-manufacture, after they have been dyed and dried. This process is sometimes termed "stringing."
GLYPTOGRAPH.— An engraving or carving on a precious stone.
GOODS.— The raw oils, fats and greases employed in soap making.
GOTHIC.— A term used by American printers to describe a style of square-cut printing-type very similar in appearance to the old Roman mural letter. In England this title is given to a boldface antique type.
GRAINING.— In leather manufactures, the impressing of skins with a fictitious grain or surface, to imitate more valued leathers.
GRAIN TIN.— Tin of the finest quality produced in this form by striking it a sudden blow when it is heated to near its melting point. Being brittle at this temperature, pure tin falls into a mass of grains.
GRATING.— In spectroscopy, a surface ruled with very fine lines, 5,000 to 40,000 to the inch; if on glass, it is called a Transmission Grating; if on metal, a Reflection Grating.
GRAVEL.— Used in brewing to denote the appearance of the beer when yeast-cells are floating about in it in the form of fine "gravel."
GRAY PIG.— Pig iron which shows a dark gray crystalline fracture, due to its content of graphitic carbon; as distinguished from white pig, which is a definite carbide of iron.
GRAY SOUR.— In cotton bleaching the dilute hydrochloric acid bath, employed to dissolve out the lime soaps formed in the lime boiling.
GRIZZLE.— A brick which has been slack-burned but is hard enough to hold its shape.
GRIZZLIES.— An arrangment in the mine sluice to receive and cast aside all the large stones brought down by the current during the process of washing the auriferous gravel.
GUARDS.— In book-binding, the narrow strips of paper bound in with the leaves at the back of the book to allow for pasting in material, as in a scrap-book.
GULLET.— The hollows between the teeth of a circular saw The filing out of these hollows as the teeth wear down is called gulleting.
HACKLING.— In flax-manufacture "hackling" is the process of preparing the flax for spinning by the removal of all foreign substances and smoothing and equalizing all the lengths of fibre.
HALF-BOUND.— A style of binding for books in which the backs and corners are of leather; as half-calf, half-morocco.
HALF PLATE.— In photography a standard size of glass plate, measuring 4¼ by 6½ inches.
HALF-TONE.— A term used to designate a photographic process in which a screen made either of netting or ruled glass, is interposed between the lens and the sensitized plate, and from the image thus produced, a positive image is made upon the prepared metal plate. This is etched into relief by the use of acids.
HALL-MARK.— A term used industrially to designate any official stamp that has been placed upon an object of trade to denote genuineness.
HARD-CURED.— A term used in the fishing industry to designate that the fish specified has been cured by being thoroughly dried in the sun after salting, a process by which all the moisture has been evaporated.
HARDENING.— A process used in hat manufacturing, by which the bodies of the hats are rubbed and pressed hard for the purpose of felting the material as well as to diminish the size and render them more dense. A hardening-kiln is a kiln in which the transfer printing process in pottery is completed: The pottery being relieved from all superfluous oils by exposure to a low heat.
HARNESS.— The term applied to the apparatus in a loom by the operation of which the warp-threads are shifted alternately to form the shed.

HESSIAN.— A coarse cloth made of a combination of hemp, and jute and used for bagging is known as "Hessian" by the trade.
HIGH-PROOF.— Commercially all highly rectified spirits are termed "high-proof."
HOGGING.— The curvature upward of a beam between its ends — the reverse of sagging.
HOLLANDER.— In paper making, a special type of machine for beating up rag pulp.
HOLLANDS.— A term which, while formerly applied only to linens imported from the Netherlands, is now used to designate the glazed and unglazed linen cloths that are made in many places. "Brown Hollands" is a cloth that maintains much of the original color of the retted flax-fibre, it having been subjected to but little bleaching or boiling.
HONEYCOMBING.— In cloth-manufacture, a term applied to designate a thin fabric in which the stitches, running diagonally across the material, have been drawn tight in such a manner that the spaces between them are puffed or in relief.
HOP-JACK.— A term applied to a vat with a false bottom used in brewing. It is so arranged that it retains the solid substances in the mash-tubs, but allows the wort to flow away after it has been boiled and the hops have been added.
HOPPER.— Used, in milling, to denote the inverted-cone-shaped trough through which the grain passes on its way to the shaking-shoe.
HORSE-POWER.— A term used as a unit of measurement in every industry in which power machinery is used. Although several values are assigned to this unit the prevailing value, both in America and England, is Watt's horse-power, which places it at 33,000 foot-pounds of work per minute, or 7,460 megaergs per second about three-quarters of the actual power of a horse. Indicated horse-power, commonly abbreviated I. H. P., is the actual work performed by the motive power, as calculated from the indicator diagram of cylinder pressures.
HOST.— In plant industry, an animal or plant which sustains the existence of a parasite.
HOT METAL.— In smithing, metal which is at forging or welding heat.
HOT SHORT.— Applied to iron which contains so much sulphur as to be brittle when hot. Also called "Red Short."
HOUSING.— In carpentry, a joint in which the whole dimensional body of one piece of lumber is let into another piece; as with the treads and risers in a staircase.
IMPOSITION.— The act of laying pages of type, etc., upon a smooth stone slab to secure them in the chases and prepare them for the press.
INDENTION.— A term used in printing to denote that a certain amount of blank space has been left before the line, or a specified number of lines of type. An indenting of every line after the first, with an increasing blank constantly shortening on both sides is termed "diamond" indention. An indenting of every line except the first, that being of full width and so overhanging the others, is termed "hanging" indention.
INFUSION.— A term used in brewing to denote the process of preparing the mash by treating the bruised malt with water at a temperature of from 70° to 75°.
INVERSION.— The alteration of dextrorotatory cane sugar into laevorotatory fruit sugar through the action of dilute acid. The product is termed "invert sugar."
JAPANNING.— The process of coating the surface of metal, wood, etc., with varnish which is immediately hardened by exposure to high temperature.
JIGGER.— (a) In mining, a mechanical appliance for sorting ore; (b) in pottery, the vertical lathe on which is made flat ware, like plates and saucers.
JOLLEY.— In pottery, a machine used in the manufacture of cups, jugs, and other hollow ware.
JUMPER.— In mining, a heavy hand-drill resembling a crow-bar, having a chisel edge, and operated by jumping it up-and-down in the drill hole, either by hand or machinery.
KERFING.— (a) The process of preparing wood for bending without breaking by making a series of small cuts in it with a sawing-machine; (b) in cloth-manufacture, the process of removing the wool by passing it through a shearing-machine.
KETTLESTITCH.— In book-binding, the chainstitching at the head and tail of a book, holding the sections firmly together previous to binding.
KIP LEATHER.— Leather made from the skins of young cattle raised in India.
KIPPERING.— In the fish trade, the process of curing fish by cleansing them, dressing them with pepper and salt, and curing them, either by drying them in the open air, or, artificially, by subjecting them to the smoke of some prepared substances.
KNOP YARN.— In textile manufacture, a kind of yarn which has been twisted in such a way as to form knops or bulging spots.
LACQUER.— A form of varnish made with an evaporable solvent; drying by evaporation and not by oxidation and resinification as do true varnishes.
LAGGING.— The non-conducting material with which boilers and steam pipes are covered to prevent waste of heat. The term is also applied to the operation of applying such covering.
LAMINATED WORK.— In carpentry, the beams or ribs built up from thin layers fastened together.
LAP.— In woolen manufacture, the fleece as it is delivered by the condenser.
LARRYING.— Bedding the inside bricks of a thick wall in thin mortar.
LAW CALF.— In book-binding, the calfskin commonly employed in binding law books. As a rule it is not dyed, and has a whitish appearance.
LAYER.— The vat in which hides are left to lie for six to ten months in a strong solution of tannin, towards the end of the tanning process.
LAYING.— The term is applied to two distinct stages in rope-making: (1) the twisting of three or more yarns to form a strand; (2) the twisting of three strands to form a rope. The machine that performs this operation is termed a "laying machine," the wooden cone placed between the strands to prevent a slack twist is termed a "laying-top."
LINE.— In linen manufacture, the best part of the flax fibre after hackling. If the roots and tips of the stems are cut off, it is more valuable, and is called "cut line."
LINGOES.— Lead weights varying from 12 to 20 pounds, steadying the harness in silk looms.
LOCK NUT.— A thin auxiliary nut screwed down upon an ordinary nut to prevent its loosening.
LOUVER.— A ventilating opening built like a Venetian blind, but with the slats not movable. It excludes rain, but admits air freely.
LUTE.— The refractory cementing material used to fill joints and cracks in high temperature furnaces.
MACERATION.— The softening of substances by soaking them in a fermenting liquid of a warmish temperature.
MACKLED.— In printing, the effect on a printed sheet which has dragged on the inked type at the moment of impression.
MANIFOLDING.— A term used in business circles to denote the process of making several impressions of a single letter or document by one operation, as by means of a manifolding-machine, or by the use of carbon paper.
MASH.— Used in brewing and distilling to describe the mixture of ground grain that has been infused in warm water.
MELLOWING.— In tanning, the aging of the tanning liquors through fermentation. The term is applied also to a similar process which goes on in harsh leathers, when dampened and laid in a pile.
MERCERIZING.— Treatment of cotton cloth with a cold solution of caustic soda while stretched taut, the soda being dissolved away by acid before the tension is released. The cloth becomes stronger, takes dye more readily, and acquires a silky lustre.
MILLING.— (a) The process of manufacturing cereals into flour or meal. There are two methods of milling: (1) low milling in which the grain is ground but once before being bolted, and (2) high milling, in which it is ground repeatedly; (b) in pottery, the operation of grinding and mixing the slip; (c) the process resorted to in tanning to open and soften the pores of hides; (d) in cloth manufacture, the process of felting cloth to thicken it; (e) the machining of metals with revolving cutters; also the corrugating of the rims of discs, coins, etc.
MOROCCO.— In book-binding, a fine quality of tanned goat-skin.
MUFFLER.— An arched oven-like furnace in which crucibles are heated without direct exposure to the flames.
MULE.— In spinning, a reciprocating machine which draws and twists the thread when moving in one direction, and winds it on spindles on the return.
NIGGER.— In soap making, the dirty, watery layer which settles in the soap pans during the manufacture of filled soaps.
NIPPLE.— A short piece of pipe having a right-hand thread cut its entire length on the outside surface.
NOBLING.— The squeezing and hammering of a mass of spongy iron from a puddling furnace, to weld it into solid metal.
NOILS.— Small masses of clustered wool fibres removed from wool fleece by the combing machines.
PADDLING.— A method of tanning light skins in a vat in which a revolving paddle keeps liquor and skins in constant motion.
PANNING.— In placer mining, the gentle rotary shaking of a mass of gravel and water in a miner's pan so as to facilitate the settlement of the gold particles to the bottom. The fine sand and float with some of the water is allowed to slop over during the panning.
PASTE WASH.— In book-binding, a dilution of paste with water, used as a surface on which to lay the glair (q.v.) previous to gilding.
PATINA.— The delicate green incrustation which gathers on the surface of copper and bronzes after long exposure to the air. The finest patina is formed on those bronzes in which tin is in large proportion, and little or no zinc. It is imitated by immersing bronze in acetic acid.

PICKING.— In weaving, the throwing of the shuttle by the picker, or driver.
PIECE-GOODS.— The trade name for fabrics that have been woven in lengths suitable for retail sale by linear measure.
PIG.— (a) In glass manufacture, the grooved iron support for the blowpipes or working rods at the mouth of the glass furnace; (b) the form in which newly melted iron or other metal is cast for marketing.
PITTING.— A defect in varnish work showing tiny holes scattered over the surface, due to varnishing upon a damp or greasy surface.
PLACE BRICKS.— Soft bricks of use only for interior walls where they will be covered with plaster.
PLUS THREAD.— A thread cut on a bulge of a bolt or rod which has been made thicker where the thread is located, so that the diameter of the substance of the rod is not reduced by the depth of the thread.
POCKET.— In mining, a cavity containing a mass of ore which is not connected in any way with a vein or lode.
POINT.— The unit of measurement in types, each point being about one seventy-second of an inch. The various types in use in the United States and their relative sizes in "points" are as follows: Excelsior, 3 points; brilliant, 3½; semi-brevier, 4; diamond, 4½; pearl, 5; agate, 5½; non-pareil, 6; minion, 7; brevier, 8; bourgeois, 9; long primer, 10; small pica, 11; pica, 12; English, 14; two-line brevier, 16; great primer, 18; paragon, 20; two-line small pica, 22; two-line pica, 24; two-line English, 28; four-line brevier 32; three-line pica, 36; double paragon, 40; four-line small pica, 44, and four-line pica, 48 points.
POINTING.— In masonry, a neat finishing of joints between bricks or stones; accomplished by scraping out the rough edges of the original mortar and filling in carefully with a finer grade of mortar, which is often colored.
POLING.— In metallurgy, the reduction of copper oxide in molten blister copper, by the inserting into the liquid metal a pole of green wood. If too much wood is used the copper is said to be overpoled; if too little wood, it is underpoled.
PONTY.— In glass manufacture, an iron rod tapered for part of its length, used in working molten glass. In some localities it is called a "working iron."
PORGIE.— The raw material, largely menhaden, and much of it offal, from which fish oil is extracted.
PORTER.— In metal working, a bar attached to a fagot of rods or a forging, by which it is held and guided during the process of hammering.
POT ARCH.— In glass manufacture, a small furnace in which the glass pots or crucibles are fired before being used in the melting furnace.
POTSHER.— In paper manufacture, a machine for breaking and bleaching pulp.
POT METAL.— An alloy of copper and lead, with sometimes small additions of zinc and tin, used as a cheap substitute for brass.
PRIMING.— (a) The first coat of paint applied upon new work as a foundation for the subsequent coats. It is rich in oil, and has enough white lead to make a firm attachment; (b) the technical name for the foaming or frothing of water in a steam boiler, caused by greasy or dirty water, or by forcing the fire.
PROOF BAR.— In metallurgy, a rod of steel laid with a charge in a cementation furnace, and withdrawn at intervals to give evidence of the degree of progress of the operation.
PROOF SPIRIT.— That grade of dilute alcohol or alcoholic liquor which contains 50 per cent by weight of absolute alcohol. A larger percentage is "overproof," a smaller, "underproof."
PUDDLING.— (a) In metallurgy, the conversion of pig iron into malleable iron by burning out the carbon, sulphur and phosphorus in association with free atmospheric air; (b) the stopping of leaks and crevices in a reservoir with a "puddle" of clay with a little water.
PUGGING.— The rough plaster or slag wool filling placed between the beams of a floor as a deadener of sound.
PUG MILL.— In brick making, the mill in which the ingredients are mixed together. Also used as to a cement mixer.
QUARTER-PLATE.— A term used in photography to denote the size of a plate. Thus, a quarter-plate measures 3¼ x 4¼ in.; a half-plate, 4¼ x 6½ in.; a whole plate, 6½ x 8½ in.
QUENCHED STEEL.— Steel which has been hardened to an extreme degree by plunging it when red hot into cold water.
QUICKLIME.— Lime fresh from the kiln which has not absorbed moisture from the air and become air-slaked.
QUINCUNX.— A method of setting a group of fruit trees so that four of them stand at the corners of a rectangle and the fifth at the intersection of its diagonals.
RABBLING.— The stirring process in puddling iron, effected with a bar with a hooked flat end, called a rabble.
RACING.— A sudden increase in speed of an engine when released from its load; as when the propeller of a steamship is lifted from the water by wave motion in stormy weather.
RACKING.— In liquor making, the aging of the liquor by allowing it to flow in small streams or a very thin sheet from one vessel to another, thus exposing it to the air.
RAG BOLT.— An iron bolt with barbs or an enlarged end for embedding in masonry so it cannot be withdrawn.
RAGLET.— The groove cut in a wall into which the flashing (q.v.) is imbedded.
RAISING.— In woolen manufacture, the operation of drawing out a nap of fibre on the cloth by means of teazles; as in beavers, meltons, and pilot-cloth, and in blankets.
RECTIFY.— To redistil, as in making whisky, which is said to be rectified when it has been twice distilled.
RED SHORT.— See HOT SHORT.
REDUCING FURNACE.— A furnace in which the metallic elements are separated from their ores; as in a blast furnace.
REEDY.— In weaving. a streaky appearance due to the threads of the warp rolling in the splits of the reed.
REEF.— In mining, the outcrop of a vein of ore.
REGENERATING FURNACE.— A furnace in which the heat of the waste gases is used to heat the incoming air-blast. Where gas is used for fuel this also is heated by the hot waste.
REGISTER.— In printing, the accurate adjustment of type and paper so that the second page of a leaf is printed exactly on the back of the first page imprint.
RENDERING.— The first coat of plaster laid on a brick wall.
RETTING.—The treatment of flax by soaking it in water in which certain bacteria carry on a fermentation which releases the fibres.
ROAN.— A tanned and dyed sheepskin used in book-binding. It resembles Morocco, but is cheaper and not so durable.
ROASTING.— The process of heating certain ores to a temperature lower than the reducing point. It secures oxidation and the elimination of sulphur, and thus simplifies the subsequent reduction.
ROVING.— In textile manufacture, the tape-like band of sliver after preliminary twisting, and previous to spinning.
RUMBLE.— A revolving cylinder in which small castings are placed so that they may be cleaned of adhering sand and mould by chafing against each other.
RUSSIA.— In book-binding, a leather made of the skins of young cattle treated on the flesh side after tanning with the oil of birch, from which it acquires its characteristic odor. Cheaper grades are made of goat or sheep skins.
RUST JOINT.— A joint made in iron piping by filling the gap with a mixture of iron filings and sal ammoniac, which in a short time forms a compact hard and waterproof mass.
SAFETY PLUG.— A plug of fusible metal set into the shell of a boiler, and which melts when the rising pressure raises the temperature to the danger point, allowing the steam to blow off.
SALT A MINE, TO.— A swindling operation by which a mine is made to seem more valuable than it really is by the surreptitious introduction of ores obtained elsewhere.
SCREED.— A narrow strip of plaster laid accurately to the required surface, and used after hardening as a guide for the floats.
SETTING.— In leather manufacture, the smoothing and stretching of a hide until all creases and wrinkles are obliterated.
SEVEN POUND LEAD.— In plumbing, sheet lead of such thickness that one square foot weighs seven pounds.
SKIVER.— In book-binding, the thin grain split of sheepskin used for cheap leather bindings.
SHELLS.— Those parts of the lay in weaving in the grooves of which the reed fits. They are of two classes and are termed "upper" and "under" shells.
SLIVER.— The textile fibres gathered into a tape-like strand preliminary to roving and spinning.
SMUDGE.— In plumbing, a mixture of lampblack with other substances, smeared over a piece of work to prevent the solder from taking hold where it is not wanted.
SOAKING.— In metallurgy, cooling slowly a freshly cast ingot of steel in a soaking-pit — a hole in the ground fitted with brick chambers to receive the ingot and allow its heat to escape gradually
SOD OILS.— The oils obtained by pressing skins which have been curried with cod, whale, or olive oils. When refined, sod oils are highly esteemed for watches and other delicate machinery.
SOUPLE.— Silk fibre from which about half of its natural gum has been removed, rendering it lighter in weight and softer in feel.
SOURING.— In leather making, the treatment of leather with weak organic acids, to remove stains and bleach the surfaces preparatory to dyeing.
SPINNING.— In metal working, the formation of round hollow ware by pressing sheet metal into a mold revolving on a lathe.
SPLIT.— A skin which has been split into two layers parallel with its surface; usually effected by a cutting machine.
STOVE SCREW.— A bevel-headed screw with the thread cut close up to the head; used particularly for holding parts of stoves together.
STRIKER.— A pronged lever set astride a driving belt for shifting it on or off the driving pulley
STRIPPING.— The tearing or breaking off of the threads of a screw or the cogs of a gear-wheel.

SUINT.— The natural grease of sheep's wool. When refined, it is called lanoline.
SUMP.— In mining, an excavation below the level of the mine floor, in which water collects.
TACKY.— The condition of the surface of paint or varnish before it is quite dry, so that it is slightly sticky when touched gently with the dry finger.
TAP.— In pipe-fitting, the tool which cuts internal or female threads. The tap first used in this operation is slightly tapered, and is called the "taper tap."
TEMPERING.— In pottery, the mixing and working of the clay into proper condition for molding.
TOOLING.— In book-binding, the ornamentation of a book cover by pressing lines into it with heated tools. They are "blind lines" if without gilt. A book so ornamented is said to be tooled.
TORCHING.— The coat of plaster applied on the under side of a roof of tiles laid on battens.
TOSSING.— In metallurgy, the oxidation of impurities in melted tin by lifting the metal in ladles and pouring it slowly back from a height, thus exposing it to the air.
TOUTER.— Industrially, a person who makes it his business to solicit trade for a shop.
TOW.— The short and twisted fibres of flax separated out in the process of combing. It is carded and spun into coarse rope yarns.
TREBLES.— Sheet iron of gauges 25 to 27 in the Birmingham wire scale.
TREE CALF.— In book-binding, a brown calf which has been stained and squeezed to produce a conventional tree-like pattern on its surface.
TUP.— The principal mass of iron in a steam hammer head to which is attached the steel face piece.
TUYERE.— The nozzle through which the air-blast enters a blast furnace.
UNION.— In textile manufacture, a cloth in which the warp is of one kind of fibre, and the weft of another.
VALLEY.—The V-shaped hollow between two intersecting roof surfaces.
VAMPING.— In leather making, the undue swelling of a hide during the liming process.
VENICE TURPENTINE.— An oleo-resin obtained from the sap of the larch. It dries very slowly and with considerable body.
WALING.— The horizontal pieces which support the planking at the sides of a trench.
WALL.— Used in mining to denote the surfaces of the rock between which the ore is inclosed. If the vein is inclined at such an angle that the ore is over the miner's head it is termed a "hanging" wall; if it is beneath him it is called a "foot" wall.
WARBLE.— In leather manufacture, a small hole in the hide pierced by the bot-fly.
WARP.— (a) In agriculture, the operation of fertilizing a poor piece of land by artificial inundation from waters which have large quantities of earthy matter; (b) in weaving the threads that extend lengthwise in a loom. The roller upon which the threads are wound is termed the "warp-beam"; the machine which treats them with size before they are wound is the "warp-dresser," while the machine which draws the warp threads through the dye beck is termed the "warp-dyer."
WASH.—Used in mining to denote the process of separating the ore from earthy and other matter by the employment of water. The fermented wort from which the spirit is extracted in distilling is also termed the "wash."
WATER GAS.— A fuel-gas produced by blowing steam over a bed of red-hot coals. It carries about 40 per cent of carbon monoxide, and is a deadly and quick poison. It is sometimes used for illuminating with Welsbach mantles, and is sometimes carburetted so as to give the ordinary yellow gas-flame. Its use in house lighting is forbidden in many communities.
WEFT OR WOOF.— In weaving, the thread which is carried by the shuttle, and is laid transversely to the warp.
WINNING.— The work of developing a mine preparatory to the work of mining is termed "winning."
WIPED JOINT.— In plumbing, a joint made to connect two ends of lead pipe which abut each other. One end is slightly expanded so the the other will set into it, and the joint is then encased in plastic solder, which is shaped by continually wiping it with a cloth until it has set.
WORKING IRON.— See PONTY.

INDUSTRIAL VOCATIONAL TRAINING. See EDUCATION, ELEMENTARY.

INDUSTRIAL WORKERS. Education and Training of. Industrial education is that form of education, whether given in a school, a factory or elsewhere, the controlling purpose of which is to train for wage-earning, or to advance the power of wage-earning in the trades and industries. It must be considered from the standpoint of education as well as of industry. Education is the fitting of the individual to take his place and do his part in the life of his community and his time. Industrial education is, then, the fitting of those who are in industry effectively to serve and to achieve in and through their field of activity. There are 9,000,000 wage-earners in the factories of the United States, supporting directly and indirectly including themselves upward of 30,000,000 people. They are working in 275,791 factories. Their educational and economic development are of utmost consequence from whatever standpoint it is viewed. The joy of life, if not its purpose, is service, self-expression, achievement. The daily task may be easy or difficult. If it is simple, that is no reason for allowing the worker to do it poorly. If he can be taught to do it with proficiency in a week or a month, not to say a year, without loss of wages meantime, he has as great right and need of this brief training as a professional man to the 10 or 12 years of additional training which the public rejoices to give him without charge after the period at which the working boy leaves school.

Great as have been the faults of Germany, she so thoroughly developed the industrial intelligence of her workers as to surprise the world. Sixty-five per cent of the men in the topmost places in her industries, in both the managerial and technical fields, came from the ranks of her working boys, who quit the regular schools at from 12 to 14 years of age, but by industrial education, which interpreted their daily tasks and made clear the ways of advancement, in apprenticeship and continuation schools (wherein education is «continued» after leaving the common schools), these boys, as men, surpassed most of the graduates of her higher technical institutions in the attainment of high industrial positions.

Joy in work comes from mastery of work. We like to do what we can do well. We dislike to do what we fail to understand or do poorly. The dislike of work of many who labor is due in great measure to the state's neglect educationally in not teaching the mastery and the dignity of labor. «The latest gospel in this world is, know thy work and do it. All true work is sacred; and in all true work, were it but true hand labor, there is something divine.» (Carlisle). It is the inherent right of every person to be taught to express himself effectively and happily in some field of the world's work, small or large, and by mastery therein to serve himself and society to best advantage. Never taught one thing only that he may rest with that, but so that through the mastery of one thing and the learning of another, he may rise to the limit of his abilities. However much a nation develops its natural resources, it is economically blind if it fails fully to develop its human values, which are the one natural resource which gives value to all others, and the only one that increases with use. The economic value of the human efficiencies of the working people of the United States is estimated at more than $200,000,000,000, or five times the value of all other natural resources combined. The spiritual values, the happiness and self-respect, that come of developed efficiency are incalculable. It is for these and other considerations that each community in the

United States spends upon public education about one-third of all its tax receipts, making a national total of about $650,000,000 annually, aside from an investment of more than a billion dollars in school plants, and both items rapidly increasing. But all this is apparently with the college as the aim, although only 3 per cent of the people take the college course. About $5,000 of public funds are spent upon anyone who fits himself for a profession, but scarcely a dollar especially to fit in his occupation any one of the 96 per cent of the people outside the professions.

Education is a state function. Whatever is done must be by the several communities under the requirement and supervision of the state. Most states require attendance at the public school of all children from the 7th to the 16th year, with, however, the important provision that after the 14th year any child may secure, if he wishes, a working certificate permitting him to leave school forever, with the further provision, in some States that he has completed the sixth grade of the common school, and in other States simply that he is able to read and write the English language acceptably, this latter provision often being carelessly regarded.

Only one child in 30 graduates from the high school; only one in five enters the high school; only one in three finishes the high school; and only half the children who enter school finish the 6th grade. By the end of the 6th grade children have learned little or nothing of fractions, nothing of decimals, only a little local geography and nothing of the rights and obligations of citizenship and the social order. Investigation indicates that the great majority of that half of all American children who leave school by the 6th grade and the 14th year of age are not compelled to by financial circumstances. They leave because they have reached the period of adolescence, at which time the will and the creative faculties assert themselves and nature impels them to "do things," unconsciously to imitate Him who in the six days made the world. This impulse is especially compelling with concrete- or hand-minded children. Those who continue in school are mostly the imaginative children to whom the world of books is often very real.

The mind of man is said to be "hand-made." Through the hand the race has learned a great part of all it knows. Work must be interpreted and made an instrument of education for the vast number who apparently will be educated, if at all, only in and through the life of labor. Legislation might compel these workers to remain in the common schools away from labor and income for a short period longer, often without advantage, sometimes to their hurt, and never to their adequate education, as education must be made available throughout the better years of life.

It is coming to be generally realized that each state must, following the best practice of the countries of Europe, set up and foster, financially and otherwise, educational facilities for the effective advancement of the millions of wage earners in the industries and elsewhere, with their daily needs and experiences as the centre of interest in their educational activities. The foremost industrial nations of Europe by apprenticeship and otherwise have for generations so trained their industrial wage earners. It is commonly conceded that Germany took the lead in the year 1885 in a series of legislative provisions which in the following years have developed a system of industrial education as effective for her wage-earners as are the provisions common to all countries for professional training. She finally came to require in great sections of that empire that every working child under 16, and in the best practice under 18, shall be released by the employer for from 8 to 12 hours per week during working hours, while fresh and vigorous, for training in his occupation or in a better one if need be.

We speak of "blind-alley" and hopeless jobs as the lot of our working children. Germany discovered that there is no such thing as a "blind-alley" job; that there is no job but may lead to high accomplishment under intelligent direction. Consequently 85 per cent of American working children are in "blind-alley" jobs, from which their elders see no way out, while in Munich 85 per cent of the working children are trained in connection with their work in ways that lead readily to high places.

France, Switzerland, Denmark and other nations have legislated in effect like Germany but less extensively. England, impressed by the Continental practice, and especially by German methods and success, planned so to legislate in 1914 but was deterred by the World War. She paused, however, at the height of the conflict, on 8 Aug. 1918 to enact educational measures requiring every child to attend the regular schools from the 5th to the 14th year of age and empowering local authorities to increase the compulsory period until the 15th year. Compulsory day continuation schools must be established for all young persons, unless they are being otherwise educated, up to the age of 16, and after 1925 up to the age of 18. The minimum number of hours of attendance per year at continuation schools shall be 280 and after 1925 shall be 320. Thus England, formerly the most backward of the great European nations in vocational training, takes an advanced position, far ahead of the United States.

Of all these nations, Germany failed to require the teaching of citizenship, of the rights, duties and obligations of the worker as a member of society. In 1903 her greatest authority, Dr. Kerschensteiner, lamented that her industrial schools "did not contain a single subject of instruction which serves any other purpose than the acquisition of technical skill and knowledge, or the promotion of trade efficiency." Since that time, a poor beginning was made in this training but in a way regretted by many of her own leaders in that it did little more than inculcate a false exaltation of her ruling classes and a blind obedience in all others. What we sow, we reap. To fail to educate in efficiency is to suffer inestimable economic loss. Not to teach the duties and obligations of citizenship, is to endanger the democracy of the world.

In the United States in the last 15 years the legislatures of several States have enacted permissive legislation authorizing local boards of education to require the attendance of all working children under 16 upon part-time or continuation schools, but in all these States only one city, Boston, had the courage to act in 1916, with New York city following later in a less extensive way.

State legislation which merely authorizes a local community to require the attendance of its working children upon continuation schools is therefore shown to be inadequate and virtually useless. It is a shirking of legislative responsibility as respects the lives of working children. If the State as such will not safeguard its children, single communities will not.

In 1911 Wisconsin required that every working child in cities of 5,000 population or more attend continuation school for four hours a week until 16 years of age for eight months annually, which provision was later extended to eight hours per week for 10 months until 17 years of age. This legislation proved entirely practicable. It was readily accepted by employers and all others as of high social and economic advantage and is evidence that any State can thus serve its working people. In 1915 Pennsylvania required that every working child under 16, in whatever occupation, attend continuation school for eight hours weekly during working hours. All-day trade schools have proved ineffective as a means of general industrial education. They were tried and generally abandoned in Continental Europe long ago. Working people either cannot or will not attend such schools and forego income and the experiences and hopes that lie in the field of labor for the years required for training in such schools. From 1880 to 1910 there was much agitation for the establishment of these schools in the United States. In those 30 years, however, only 13 such schools were established with a total attendance of less than 2,000 students, being not more for the whole country than should receive industrial training in the average manufacturing city of 50,000 people. The training in these schools is so general in character as to lack immediate interest and not to fit for the specific tasks their graduates enter upon. The cost to the public averages from $150 to $200 per pupil per year. There are 2,000,000 working children under 16 in the United States in industry, agriculture and commerce and more than 5,000,000 under 18. All these children have equal right and need of training in their occupations. There are 30,000,000 older wage-earners to whom the opportunity for training for advancement should be open, many of whom would avail themselves of it. In a single typical industrial city, Milwaukee, it was estimated that a relatively small number of superior wage-earners in her industries in 1910 were sending $80,000 annually to correspondence schools for such industrial training as they could so secure. It was then that Wisconsin provided that her wage-earners should have education in their occupations in continuation schools directly adapted to their circumstances even as her university provides for those who are more fortunately circumstanced. Said the Pennsylvania superintendent of schools, "to educate all children who need it, through any such all-day, all-week schools as have been developed yet, would bankrupt any State." And the loss in wages to the learners would be as great as the cost to the State. The correlation of instruction in continuation schools with the work in the factory makes both work and school educational.

The cost of superior continuation school training in Europe is about $25 per pupil year. It sometimes costs less in the United States because it is not yet of the European quality. The increased interest and efficiency of the workers in the factory should equal or exceed this cost. Because of this increase in efficiency in the factory many great manufacturing institutions in the United States introduced training departments at their own expense during the war period for the training of new workers and the up-grading of old employees, spending in several instances as much as $50 per learner. By this expenditure the employer secured a more contented worker, reduced labor turnover greatly and reduced the wastage of materials. Since the war many of these establishments are continuing these training departments and other manufacturers are introducing them as an essential means of development for the vast production of peace times.

Among the essential provisions for industrial training for all who need it may be noted: First. It must be part-time or continuation, therefore, not requiring the worker to abstain from work and income. Second. Attendance must be made compulsory by the State for all working children under 16, or better 18, during working hours and readily available to all older persons through life at their option so that any worker may continually uplift himself by securing at all times whatever instruction he needs to qualify for the next step forward. Compulsion in the matter of school attendance of young children is only the recognition of the right of the child and the duty of the State, and this recognition expressed in terms of agreement and action. Wherever tried it finds ready acceptance. Third. Industrial schools, and equally those for agriculture and commerce, must be under the control and direction of special State and community boards whose personnel is directly representative of industry and labor. The leading nations of Europe after trial of all other methods insist upon this practical direction and place this education in the Department of Commerce or Labor and not in the department of general education. Only those with life-long and successful experience in industry can know when industrial education is truly industrial and make it so. Wisconsin accepted this principle in establishing a State Board of Vocational Education consisting of three employers, three wage-earners and the State superintendent of schools, the latter being the link between the general and the industrial schools. She also provided that the general board of education in each city appoint a board of vocational education consisting of two representative employers, two wage-earners and the city superintendent of schools, with full authority, subject only to the State board of vocational education. The Federal government, upon advice of the leading organizations of wage-earners, employers and others accepted this principle in making the Federal board of vocational education consist of the Secretaries of Labor, Agriculture and Commerce and one lay representative each, from labor, agriculture and commerce. This Federal board is advisory to

State boards of vocational education and distributes Federal aid in amounts increasing annually until 1925 and thereafter when it aggregates $7,000,000, being $3,000,000 each for industry and for agriculture and $1,000,000 for the training of teachers, but limited in each case to not more than one-half the total spent by a State for these purposes. In Massachusetts and Connecticut a limited number of industrial schools have been highly developed under the supervision of the general State Board. This Board, however, is composed principally of, and in industrial matters dominated by the judgment of, especially qualified manufacturers. In American States where academic school influences control in the direction of industrial education, as formerly in Europe, this education is remote, impractical, lacking in "production" sense and ineffective. Fourth. Training in industrial schools must be upon production, i.e., the making of real things for commercial use in the same manner as they are produced in factories. In Massachusetts it is required that industrial schools "shall conduct a productive shop which conforms in all desirable factors with commercial standards. The work on which pupils are trained shall be planned and perfected with reference to its commercial value and shall be judged by commercial standards." "The most effective shop work is that done on a commercial basis for an outside customer. Work done to fill pupils' orders is least satisfactory." "The general atmosphere, system, standard, practice and administration of the school shall be that of a good industrial shop."

It has been objected to this method that it commercializes education and takes bread out of the wage-earners' mouths by supplying the market from public institutions. The value of school products, however, is inconsequential, being about one-third of the salaries of the teachers who are taken out of industry, or from one-fifth to one-tenth of what these teachers would produce were they left in industry as wage-earners. The leaders of labor support this position in all communities where it has been well worked out. Fifth. Teachers of processes and operations must have had extensive practice and successful experience in factories. They should have that developed "sixth sense" common to the professions, indicating thorough appreciation and understanding of the intricacies and methods of the production. Only the related academic instruction may be given by instructors whose shop experience has been less extensive. Sixth. Every trade must be taught, that of the baker, jeweler, barber, tin-smith, potter, watchmaker, decorator — every trade requiring developed skill — and not the four or five trades only that are commonly taught in old-time trade schools. In Munich there are some 60 schools teaching 50 trades, besides 15 schools for the least intelligent workers who must follow the unskilled trades. These workers are taught to keep personal accounts, how best to use their slender incomes and the fundamentals of citizenship. Seventh. Instruction must be directly correlated with the daily tasks and experience of the learner. Boys and men learning the butcher's trade must be taught to cut all kinds of meat and figure on shrinkage, waste, etc. A butcher shop cannot be in a public school. Consequently a local commercial shop must be used. A large city can have a commercially operated bakery in its industrial school. Smaller communities can readily arrange to use for a few of the dull hours of the day the facilities of a local baker, he giving the practical instruction and advising concerning the related instruction.

Instruction in citizenship should make much of local institutions, social and industrial, as a point of contact.

Mathematics and English should in each case be taught in terms of the learner's occupation.

The following brief excerpt from Industrial Continuation Courses are illustrative:

(a) From a course for boys from 14 to 18 in a school in a tannery;

Monday — REVIEW OF CHROME RE-TAN AND COMBINATION TANNAGE:

I. Chrome re-tan.
  1. Solution for re-tan.
    a. 2 per cent tannoline to 100 lb. leather.
    b. Run in drum two hours.
    c. Horsed five hours.
  2. Purpose.
    a. To tan green spots.
    b. To make leather firm and solid.

II. Combination 10 hours.
  1. Cossack only has combination tannage.
  2. Chrome re-tanned first.
  3. Horsed 10 hours instead of five hours.
  4. Solution.
    a. Extracts used are quebracho, hemlock, spruce, gambier.
    b. About 100 lb. extract to 1000 lb. leather.
    c. Run in drum five hours.
  5. Horsed 10 hours.

Tuesday — LECTURE OF FOREMAN OF STUFFING DEPARTMENT.

I. Definition of stuffing.
II. Purpose of stuffing.
III. Kinds of leather and processes.
  1. Hemlock tannage.

    1. Location.
    2. Establishment.
    3. Development.
  (Note: Apply foregoing outline under II to several local industries).

Eighth. Most of this training for working children must be given in public schools and a large part of it for older workers. Schools or training departments must, however, be set up in factories under State supervision for that great part of the 9,000,000 factory workers who do not need or will not take an extended course in training in the industrial schools.

The development of industrial training departments in factories for the quick intensive fitting of new workers to their tasks and the upgrading of more experienced workers has been one of the interesting experiences of the great war. Such training departments are also known as vestibule schools. France and England found these factory training departments a war necessity for replacing enlisted, skilled men by women and for developing in old employees the high technical skill required in war production. The French Ministry of Munitions early in the war required every manufacturer employing 300 workers or more to install these training departments. The British Ministry of Munitions in many of its contracts for war supplies required this of her manufacturers. In the United States the Council of National Defense through its section on industrial training assisted manufacturers in their development of training departments in the earlier months of the war. The United States Training Service, established in August 1918, then became the Federal agency in this field. Since the armistice so many factories are using this method as to give promise of a great improvement in American productive methods and of happier and greater production by the

wage-earners. It is estimated that 25 per cent increase in production is secured through factory training departments. Of the 9,000,000 industrial workers, nearly one-half are in 3,000 factories; 1,613,000 are in 833 factories of 1,000 or more employees each. The desirability of developing in these factories inexpensive and intensive industrial training highly acceptable to wage-earners and employers is evident. The fast developing appreciation of industrial education available to all who need it of whatever age, and of using to this end the resources of the public schools and the vaster and infinitely varied facilities of the factories of the country upon the invitation of their owners is one of the better omens of the new democracy. See EDUCATION, INDUSTRIAL.

H. E. MILES,
Chief of Training, United States Training Service, Washington, D. C.

INDUSTRIAL WORKERS OF THE WORLD, or I. W. W., a labor organization of revolutionary character, with tenets similar to those of the Syndicalists. The strike of the Western Federation of Miners at Colorado in 1903 brought to a head the grievances of labor and its need for new centralization. A conference of labor leaders was held at Chicago in 1904, which resulted in a general convention of labor delegates a few months later at which the leading principles of such an organization were outlined. Another convention took place in 1906. The many factions which constituted the labor revolutionists fought for supremacy, and several schisms widened and separated the groups. The "revolutionaries" opposed the "reactionaries"; the "political" and "industrial" socialists could not agree; and the local trade-unionists were pitted against the believers in one all-embracing union of workers. A fourth convention produced the final preamble which may be briefly outlined by some of its leading principles: "The working-class and the employing class have nothing in common. Between these two classes a struggle must go on until the workers of the world organize as a class, take possession of the earth and the machinery of production and abolish the wage system." "It is the historic mission of the working class to do away with capitalism." "An injury to one is an injury to all." The organization differs from syndicalism in that it proposes to build up, after the pattern of capitalistic organization, but on revolutionary lines, a tremendous and all powerful organization of all workers. It does not desire to remodel existing trade unions, but to establish a new and broader organization. It has no use for mediation, conciliation or arbitration, and considers no contract binding on employees. To strike whenever they can inconvenience employers most is the fixed policy of the members. They endorse sabotage (q.v.), the general strike and all forms of direct action.

The I. W. W. is composed of 535 recruiting stations; industrial unions having a total membership of 85,000; and five national administrations at Hawaii, Australia, New Zealand, Great Britain and South Africa respectively. The constitution and by-laws provide for membership of local industrial unions directly federated with headquarters, local recruiting unions, industrial councils and individual members. The membership of these last mentioned fluctuates considerably, depending on disturbed conditions and strikes for increase. Recently the I. W. W. has made tremendous efforts to reach the agricultural laborers. All alliances with political parties are refused. The organization has trained strike leaders and propagandists throughout the country who have been conspicuous in notorious campaigns, notably the Lawrence, Mass., strike in 1912, the strikes in the mines at Bisbee, Ariz., Mesaba Range at Minnesota and Everett, Wash., 1916. The organs of the movement are *Solidarity*, the official English paper; the *Industrial Worker* published at Seattle, Washington and papers in foreign languages including the Hungarian, Polish, Lithuanian, Spanish, Yiddish, Swedish, Slavonian. Defense of imprisoned leaders has become one of the points for concerted effort among this group of revolutionists.

At the convention held on 20 Nov. 1916, a pertinent war declaration was adopted. "We condemn all wars and for the prevention of such we proclaim anti-militarist propaganda in time of peace, thus promoting solidarity among the workers of the entire world; and in times of war, the general strike in all industries." The unpatriotic efforts of the I. W. W. in this latter direction after the United States entered the war in 1917 were suppressed by the government with severe measures of imprisonment and fines. (See SYNDICALISM). Consult Brooks, J. G., 'American Syndicalism; the I. W. W.' (New York 1913); Brissenden, S. F., 'The Launching of the Industrial Workers of the World' (Berkeley, Cal., 1913). In recent numbers of the 'Readers' Guide to Periodical Literature' complete lists of timely magazine articles will be found describing and discussing the latest operations of this organization. Consult especially Parker, C. H., 'The I. W. W., A Different View' (in *Atlantic Monthly*, November 1917).

INDUSTRIALISM, a term of somewhat vague significance, employed in different senses by different writers. With some it is a type of social organization; with others it means our present system in which industry predominates as militarism did in past centuries. According to Spencer it is a theoretically possible form of society purely industrial in all its activities. The last is the sense mostly frequently attacked by preachers, pseudo-reformers and others.

INDUSTRIES, Welfare Work in. An interesting and valuable feature of modern industrial life is the attention given by many employers to the safety, comfort and health of workers. The new impetus in this field takes its origin not only from philanthropic and paternalistic motives, but from the demands of modern business for scientific management and industrial efficiency. In addition to reform legislation making many such measures effective, an increasing number of employers have found it expedient to adopt various methods for safeguarding and protecting their employees. The result has been manifest not only in the improvement of the immediate working environment and the creation of numerous safety devices, but in the provision for lunch and rest rooms; recreation facilities, rest periods in monotonous work; medical inspection and attention which includes all arrangements from simple first aid to elaborate hospitals, factory physicians, sanitariums, home care by nurses; social organization and education of workers; housing facilities; insurance, pension, etc. A welfare secretary is often employed whose duties consist in caring for the general personal interest of the employees, and in addition, the engaging and readjusting of labor, the meeting of complaints and solving the problem of discipline. The principle of the entire work is the most economic use of the energy available by the right adjustment between the worker and the machine and the adaptation of both to the general work. The result from the employer's point of view has been a marked increase of output because of the lessening of fatigue, the adjusting of the "man to the job" and the heightening of interest on the part of the employed. In connection with the European War, studies of the labor problems have established the fact that such measures for industrial betterment heighten human efficiency and lessen the fatigue and monotony consequent to excessive demand for labor on diminished physical forces. (See LABOR LEGISLATION IN THE UNITED STATES). Consult Proud, E. D., 'Welfare Work' (1916); Cadbury, E., 'Experiments in Industrial Organization' (London 1912); Hoxie, R. F., 'Scientific Management and Labor' (New York 1915); Whitney, A. L., 'Rest and Recreation Rooms and Rest Periods for Employees' (in monthly review of United States Bureau of Labor Statistics, Vol. V, October 1917, No. 4); id., 'Medical, Surgical and Hospital Treatment for Employees' (id., September 1917, pp. 59–67); Goldmark, Josephine, 'Fatigue and Efficiency' (1912).

INDY, an'de', **Paul Marie Théodore Vincent d',** French composer: b. Paris, 1851. His early instruction on the piano was received from his mother under whose tutelage he mastered the instrument before his 14th year. Subsequently he studied under Diémer, Lavignac, Marmontel and César Franck. He served in the army during the war with Germany in 1870–71. He entered the Conservatory of Paris after the war and in 1873 was a member of the organ class there. Subsequently he was employed as choirmaster by the Société des Concerts du Châtelet. He was made manager of the National Musical Society in 1885, and president five years later. He served also as inspector of music in the Paris schools and managed several choral societies. In 1896 he was one of the founders of the Schola Cantorum. He visited the United States in 1906 and there conducted his own works with the Boston Symphony Orchestra. He has written the operas 'Fervaal' (1897) and 'L'Etranger' (1903) but is pre-eminent as a composer of instrumental music. He has written 'Jean Hunyade,' 'La forêt enchantée' and 'Wallenstein,' symphonic poems; two orchestral suites, 'Le chant de la cloche,' a dramatic legend; orchestral pieces, some chamber music, choruses, piano and organ pieces. He published biographies of César Franck (1906) and Beethoven (1910). In collaboration with Sérieyx he wrote 'Cours de composition musicale' (3 vols., 1902–12). Consult Borgex, L., 'Vincent d'Indy; sa vie et son œuvre' (Paris 1913) and Sérieyx, A., 'Vincent d'Indy' (ib., 1914).

INEBRIETY. See ALCOHOLISM.

INERTIA, in physics, denotes the mechanical continuance, or persistence, of energy in existence. The German language has two words for our word "inertia." An explanation of these should serve as an illustration of the way in which inertia is used in a dual sense by English-speaking physicists. *Beharrung,* the better of the two German terms, because it is a positive expression, has been defined above. The other German word is *Trägheit,*— a literal German translation of what we commonly mean by inertia. But there are some experimental as well as theoretical considerations which reveal that whenever one understands by inertia the non-appearance of new energy, or motion, or activity,— and this is the meaning of *Trägheit* — one does so by laying all the emphasis on a merely negative characteristic of inertia. A gentleman of Vienna, J. Popper, alluded while conversing with Prof. Ernst Mach, a distinguished physicist, to an interesting parallelism subsisting between the meaning of inertia as used in physics and the meaning of heredity as employed by biologists. Mach's version of Popper's remarks was given in an inaugural address delivered on assuming the rectorate of the University of Prague, from which we quote as follows: "Take a body in motion; the body retains the velocity acquired in (or *inherited* from) the interval of time just preceding, except it be changed in the next moment by an accelerating force. In the case of the body in motion the change of velocity (abänderung) was looked upon as a matter of course, while the discovery of inertia (or persistence) created great surprise; in Darwin's case, on the contrary, the heredity (or persistence) was taken for granted, while the principle of variation (abänderung) appeared novel." From this is revealed the notion of continuity or persistence underlying both the idea of heredity and the idea of inertia. Inertia thus places emphasis on the idea that so long as nothing interferes to bring about change everything in nature will remain as it is. The law of inertia indeed explains itself. Wherever we meet with it, it need not be accounted for. An explanation becomes necessary only when inertia appears to be lacking.

The term is thus used to denote the law of the material world that all bodies are absolutely passive or indifferent to a state of rest or motion, and would continue forever at rest, or persevere forever in the same uniform rectilinear motion, unless disturbed by the action of some extrinsic force. Even in ancient times thinkers attributed to matter a certain inaptitude, reluctance or renitency to motion. But that a body in motion required the operation of an extrinsic cause (potential or actual) to bring it to rest was first discovered by Galileo. He was led to this discovery through his examination of the principle of the height of ascent. Kepler, conceiving the disposition of a body to maintain its motion as indicating an exertion of power, prefixed *vis*; and the compound expression *vis* inertia ("force of inertia") though less accurate than inertia merely, has been nevertheless generally retained. Huygens, upon whose shoulders the mantle of Galileo fell, formed a sharper conception than the latter had of the law of inertia. He achieved this by generalizing the principle respecting the heights of ascent, a principle laid

under contribution by Galileo. Huygens writes: "If gravity did not exist, nor atmosphere obstruct, the motions of bodies, a body would keep up forever the motion once impressed upon it, with equable velocity in a straight line." It may be mentioned in passing, that the principle respecting the heights of ascent employed by Huygens in this connection, is identical with the principle of excluded perpetual motion. Newton showed that if the property of inertia is possessed to an equal degree by two different substances these substances will have equal heaviness or weight. So it appears that that part of the principle of inertia involving continuance in rest if undisturbed was known even to the ancients, and by them attributed to a certain repugnance of matter to motion. It was thus reserved for Galileo to show that the remaining portion of the principle was equally true and general.

The word inertia occurs in compounds; viz., as in moment of inertia. The moment of inertia of a body or a system of bodies upon or round an axis is the *sum* of the products obtained by multiplying each element of mass by the square of its distance from the axis. But with regard to a plane or point, the moment of inertia is the *sum* of the elements of mass each multiplied by the square of its distance from the given plane or point. There are other compounds, and phrases, in which the word inertia conveys a specific meaning. All, like the above, are defined in the better works on physics.

We gain our first conception of inertia by the attempts that we make to move bodies that are at rest, or to stop those that are in motion. As to the underlying notion of continuity inherent in the idea of inertia, we can hardly say more, philosophically speaking, than, that nothing in the known world is inconsistent with the hypothesis that all changes are really continuous. Indeed if the a priori belief in permanence or continuity had not existed the same laws which are now formulated in terms of this belief might just as well have been formulated without it. In a hypothetical sense continuity may be allowed to be the necessary condition if two appearances are to be classed as appearances of the same thing. Even if bodies are suspended freely, so that fractional forces are negligible, we find that their state of rest or motion cannot be modified without the exercise of a certain amount of muscular force; and by abstracting our own personality in the case, we gradually come to the conception of inertia as a physical property inherent in all bodies. Inertia has been popularly described as a "passive resistance" to change of motion; but this expression is objectionable because it is entirely inaccurate. Freely suspended bodies (that is, bodies that are free from frictional force) cannot be said to "resist" forces that are applied to them. On the contrary, they yield instantly to the smallest force; but a small force, when exerted upon a given body, for a given length of time, does not produce as great a change of motion as would be produced by a large force acting upon the same body for the same length of time. The conception of inertia shades insensibly into that of "mass"; the mass of a given body being proportional (by definition) to the velocity that is communicated to the body by a force of standard intensity, acting upon it for a standard length of time. See MASS; MATTER; MOLECULAR THEORY.

INEZ DE CASTRO. See CASTRO, INEZ DE.

INFALLIBILITY, exemption from the possibility of error. The word is used as applied to arguments, statements, reasoning or the formation of judgments, and does not include impeccability or exemption from the error of sin. The infallibility of the Church as believed by Roman Catholics means that "the Church can neither deceive or be deceived in matters of faith and morals"; and she is limited to the definition of truths already contained in Scripture and tradition. The seat of infallibility rests in the Pope as successor of Saint Peter (Matt. xvi, 18) and in the bishops in communion with the See of Rome, whether dispersed or united in a General Council. In the acts of the Vatican Council, held in Rome in 1870, the following is the text defining the nature of the infallibility of the Pope: "The Roman Pontiff, when he speaks *ex cathedra,* that is to say, when in the exercise of his office of pastor and teacher of all Christians; he, in virtue of his supreme apostolic authority defines that a doctrine on faith and morals is to be held by the whole Church, by the assistance of God promised to him in the person of blessed Peter, has that infallibility with which it was the will of our Divine Redeemer that His Church should be furnished in defining a doctrine on faith or morals, and that therefore these definitions of the Roman Pontiff, of themselves and not through the consent of the Church, are irreformable." The Greek Church, the Church of England and the Protestant Episcopal Church which is its representative and in communion with it in the United States, believe that infallibility resides in the universal Church in accordance with Christ's promise of the Spirit that should guide His followers unto all truth. Consult Allies, 'See of Saint Peter'; Ballerine, 'De Primatu'; 'De Potestate Summ. Pontif.'

INFAMY and INFAMOUS CRIMES, in common law the first means disqualification from giving legal evidence as a result of having committed the second, the theory being that a person capable of such crimes is incapable of speaking the truth. Both in Great Britain and generally in the United States this disqualification has been abolished by statute, and previous convictions for crime have been considered to affect a person's credibility without impairing his legal capacity to give evidence. Infamous crimes are strictly those which entailed punishments. The fifth amendment to the Federal Constitution speaks of "capital or otherwise infamous crime" and we read in 2 Dane, Abridgment, 569, 570: "Punishments clearly infamous are death, gallows, pillory, branding, whipping, confinement to hard labor and cropping." Infamous punishments include imprisonment in State prison or penitentiary with or without hard labor, and crimes which entail such punishments are undoubtedly to be considered infamous crimes, in the sense implied in the fifth amendment to the Constitution.

INFANCY. The term infancy is used variously by different writers to include a shorter or longer period of the earliest stage of human

existence. By most writers it is limited to the first 12 or 14 months, extending to the time when the baby begins to walk and to talk, and so is synonymous with a "babe in arms"; many medical authors would make it include the whole period of the first dentition, or up to about two and a half years. The characteristics of the period are utter helplessness, rapid growth of body, gradual development of muscular functions and great impressibility of the nervous system. In mankind this helplessness is more marked and the period of dependence is longer than in any other of the higher animals. It has been pointed out by John Fiske that the present elevation of man above other animals is due largely if not entirely to this lengthened period of plasticity,— to his prolonged immaturity. Man is born with only a few of the lowest vegetative capacities fully developed, such as digestion, respiration and circulation; the muscular and nervous functions are latent and only gradually develop; while the higher functions of the mind go on evolving until the fifth decade of life. A long infancy or period of immaturity means a great capacity for development.

Birth and Heredity.— The infant comes into the world with a fixed sum total of vital force, along with certain hereditary tendencies in development toward health and, perhaps, toward disease. These hereditary tendencies are all modified by the physical, social, intellectual and moral status of the child's family and surroundings: in a word, they are vastly influenced by the child's environment. Heredity was formerly regarded as the most important factor in the child's life; but heredity is really only one of three great factors,— the others being the nutrition of the child, and his physical, intellectual and moral environment. During the plastic years of infancy, childhood and adolescence, a bad heredity can frequently be overcome by proper management; on the other hand, the capital of a good heredity can be squandered. Nature always tends toward the normal or healthy, so that there is always the possibility for a bad heredity to be obliterated if only the natural tendency is assisted. More then depends on the nutrition and environment of the infant than upon its heredity.

Nutrition: Breast-Feeding.— The best method of nourishing the infant is nature's way — to have it nursed by the mother. But for various reasons this is often impossible. Modern life — and especially city life — has in some way rendered a certain proportion of women incapable of producing breast milk for their offspring. Every encouragement, however, should be given to the young mother; for it frequently happens that a second baby can be successfully nursed after failure with the first. Again, in not a few instances, the infant does not thrive upon the breast-milk, even though it may be abundant. In both these classes of cases some form of artificial or substitute feeding is a necessity. Good wet nurses are so difficult to procure in the United States that artificial feeding is generally preferable unless the baby is premature or feeble and failing: then the services of a wet nurse may be needed to save the infant's life.

Artificial or Substitute Feeding.— The best available substitute for human milk is an adaptation of fresh, clean unadulterated cow's milk. The milk should be diluted and otherwise modified to suit the infant's feeble digestive powers, and it should be given preferably, without being scalded or sterilized. In summer, or when there is any doubt as to the freshness of the milk, the cleanliness of the dairy or the careful handling of the milk, "Pasteurization," or heating the food to a temperature of 155° F. is advisable. Details as to milk modification and Pasteurization can be found in any book on "Infant Feeding." Ready-made infant foods,— the canned or bottled proprietary foods — do not contain the right ingredients for properly nourishing the infant, and their prolonged exclusive use is nearly always followed by some form of malnutrition — especially scurvy and rickets. These proprietary foods contain large proportions of sugar or starch, and so make fat babies, but such infants are generally pale, have feeble powers of resistance, and are prone to succumb to disease of the lungs or of the digestive tract. When the prepared infant foods are used as additions to milk they are less objectionable, and may at times be of advantage.

Weight and Development.— The infant that has been properly nourished before birth and is born at full term weighs on the average about seven and a half pounds — boys being somewhat heavier than girls.

During the first few days, while the nourishment from the mother is insufficient, the baby regularly loses from six to eight ounces; but it soon begins to gain, and if the nutrition is normal and the infant remains well, there will be a steady increase in weight throughout the first two years. The gain during the first year is more regular however, as well as more rapid than that during the second year. During the first three months the increase in weight each week is about half a pound: from the third to the sixth month the weekly gain is somewhat less, from four to six ounces: from the sixth to the ninth month about four ounces, and after the ninth month a little more, usually a weekly increase in weight of from four to six or even eight ounces. By the end of the fifth month the baby that has been perfectly well and is being properly nourished should have doubled its birth-weight and weigh about 15 pounds: at the end of the 15th month it should weigh three times its weight at birth. In many instances the baby will treble its original weight by the end of the first year; but 21 pounds may be considered the average weight for the end of the 12th month. Infants that were very large at birth do not increase so rapidly; while small or premature babies are apt to make a gain that is greater in proportion to their original weight. "Hand-fed" or "bottle" babies should weigh on the average about the same as breast-fed babies,— provided that they have had no disturbance of their digestion; the food must, however, have been perfectly adapted to the infant, and this is often a very difficult problem.

Height and Other Measurements.—At birth the length of the average baby is about 20 inches; during the first six months there is an increase of four to six inches, and during the second six months from three to four inches more; by the end of the second year the height is 32½ inches, a growth of over a foot since birth. By the end of the third year the stature

is one-half of the adult height. The head grows very rapidly during infancy and early childhood. The circumference of the head at birth is from 13 to 14½ inches; by the end of the sixth month it is 16½ or 17 inches; at the end of the first year 18 inches and at the end of the second year it is 19 inches. By seven or eight years the circumference of the head almost equals the adult size of 21 inches. This is visible evidence that during the first months and years of life the brain is increasing in volume more rapidly than any other organ in the body,—the head or brain-box expanding to conform to the enlarging brain. The soft spot or "fontanel" usually closes between the 15th and the 20th months. The chest is smaller than the head at birth (13 inches), but its circumference increases rapidly, so that at 18 months that of the chest and the head are equal. After this the chest grows steadily but gradually until puberty, when there is a very rapid increase for four or five years. Aside from the regular increase in weight and measurement, the healthy infant shows other signs of well-being. The baby's flesh is firm, and the skin is satiny and elastic: the color is pink, and the body and extremities are well rounded. Very fat babies are not necessarily stronger or healthier than those that weigh less: as has already been noted they are apt to be pale, flabby and of weak resistance to disease. The healthy baby is happy and playful when awake, and sleeps from 16 to 20 hours out of the 24,—longer the younger the baby. It is desirable that the growing child have a nap during the day up to the time when kindergarten work is begun; with nervous or poorly nourished children the practice should be continued until the seventh or eighth year.

Muscular and Mental Development.—These begin with the entrance of the infant into the world, but are slow in unfolding. At first the grosser movements performed by the muscles working over the larger joints, next more complex movements, and during later childhood and early adolescence the finer movements requiring nice adjustment and delicate co-ordination. Hence it is that occupations or accomplishments requiring great manual dexterity, such as violin or piano-playing, should be taken up early,—"before the hand gets stiff," as the phrase is. The first movements are those of the legs, arms and neck: they are not purposeful but merely reflex. By the sixth week the infant can hold up its head, when the back is supported, but very unsteadily until about three months old. At some time in the third or fourth month the infant makes its first voluntary movement, grasping at some object in the range of vision. Within a month or two later the baby can co-ordinate the muscles of the eyes, arm and hand sufficiently to take firm hold. Sitting alone is an accomplishment of the seventh or eighth month, and creeping also begins at about this time, if the baby is ever to creep at all. During the eighth or ninth month the baby begins to stand, having made the attempt for many weeks before; at ten or eleven months the infant can stand alone, and shortly after the twelfth month the first tottering steps are taken. It is some months before the baby is secure upon the feet, the maintenance of the equilibrium requiring nice control of many groups of muscles. Healthy infants differ greatly as to the time when they can walk alone, some walking at as early as ten months, while others may not walk until 18 months. Very fat babies walk late, but, in some instances, an excess of caution seems to be a factor. If a child is far behind in performing any of these muscular functions a physician should be consulted so that careful examintion may be made for signs of rickets or of disease of the brain or of the spinal cord.

Development of Special Senses.—For the first few days the newly-born infant avoids the light, and for many weeks cannot endure a direct bright light. Perception of light soon develops, the color first attracting attention being red. Clear perception of objects comes during the fifth month. Hearing is in abeyance for several days, a baby at birth being practically deaf; but after a week or ten days this function begins, and later hearing becomes very acute, the infant being able to recognize the mother's voice or a footstep at about three months. Loud sounds cause the baby actual pain, so severe are their impressions on the delicate auditory apparatus. The sense of touch (contact) is early developed, especially in the tongue and lips; but sensitiveness to pain is very dull during infancy. Heat and cold are recognized from an early period, the variation of a few degrees in the temperature of the food causing the baby to refuse it. Taste and smell also are present at birth, taste being very discriminating.

Development of Speech.—Speech is very closely related to the higher functions of the brain, and is therefore the last of the simple functions to develop. Usually a baby begins to say "Mamma" and "Papa," with clear knowledge of the meaning, toward the end of the first year. Next names of objects and persons are learned and soon two words are put together. Then verbs are used, and about the end of the second year little sentences are made. Pronouns are regularly the last of all the parts of speech to be used. During the third year speech develops very rapidly, the baby bringing out some new term or expression almost daily. There are great variations in the time when children begin to talk; and for this there are many reasons. Girl's generally talk earlier than boys by two or three months: babies that associate in the nursery with other children talk earlier than only children. If, however, a young child reaches the age of two years without attempting to talk, mental backwardness or organic brain disease is apt to be the cause. Tongue-tie is seldom the cause of backwardness in talking, although it does produce imperfect articulation.

Dentition — Teething.—The first teeth appear about the sixth of seventh month, but a perfectly healthy baby may have no teeth until 10 or 11 months old, or on the other hand may cut the first tooth at four months. The regular order is as follows: lower central incisors, upper central incisors, upper lateral incisors, lower lateral incisors—each pair coming at intervals of three to six weeks: at about the fourteenth month the front double teeth (anterior molars) appear in the two jaws, and four or five months later the canines, known popularly as the "eye and stomach teeth." Finally, the last four molars appear sometime between the twenty-fourth and the thirtieth month, and

these complete the 20 teeth of the first dentition. Teething babies are apt to be fretful, they have a reduced resistance against disease, and they are prone to slight disturbances of digestion. To attribute most of the ills of infancy to the process of teething is a great mistake; usually some other and better cause for the disturbance can be found if the baby is carefully examined. During the time when the successive pairs of teeth are coming through the gums, the usual food should be largely diluted, so as to prevent any serious indigestion.

Fever.—Sudden high temperature is readily produced in young children by slight causes, inasmuch as the heat-regulating centre in the brain is but poorly developed. Again, the temperature in disease is erratic and is apt to be higher than in adults suffering from the same ailment. Only persistent high temperature need cause anxiety.

Convulsions.—A characteristic of infancy is the easy excitability of the motor side of the nervous system. Hence convulsions or spasms are much more frequent and less serious than in adults. The immediate cause of the motor explosion may be an overloaded stomach, fright or mental excitement, or the fever of an oncoming disease. Severe earache, intestinal worms or a paroxysm of whooping cough may also serve as an exciting cause. Underlying or predisposing causes are a nervous heredity, malnutrition, or rickets; or there may be organic disease of the brain or the kidneys. The spasm usually begins with a turning of the eyes to one side and twitchings or grimaces of the face; there may be frothing at the mouth; then the arms and legs are rapidly contracted and relaxed; later the body stiffens out, the breathing becomes noisy and labored, the face,—especially the lips—becomes livid. Shortly afterward the body relaxes, the breathing becomes easy, and spasm ceases for the time being—having lasted anywhere from five to thirty minutes. Until the physician arrives certain simple measures are of value. The infant should be undressed, wholly or partially, and put into a warm bath (not warmer than 105° F.) to which a handful of mustard flour has been added, and the baby should be rubbed all over while in the tub for about five minutes. Then remove from the bath and lay between blankets, putting a warm bottle at the feet and an ice cap or cold compress on the head. If the baby can swallow, a full dose of castor oil should be given. Most convulsions are due to the presence of decomposing food-remains in the alimentary tract, and the spasms usually cease when the stomach and bowels have been thoroughly evacuated.

LINNÆUS EDFORD LAFÉTRA, M.D.,
Associate in Diseases of Children, Columbia University; Director of Children's Medical Division, Bellevue Hospital.

INFANT, *in law.* By the common law persons come to majority at the age of 21 years, until which time they are called in law *infants,* but by common usage in the United States the word minor prevails. This rule is practically universal, by statute, for males, but many States fix the age at 18 years for females. Infants cannot, in general, bind themselves by contracts, as they are supposed not to have sufficient discretion and ability for this purpose. But this is their privilege, and their contracts are accordingly held in general not to be void, but only voidable at their election; and they may elect to avoid their contracts in relation to personal property either after or during their minority, except such as they may have entered into for necessaries suited to their condition in life, but they cannot confirm any contracts so as to be bound by them until their majority. Contracts affecting realty are usually held not to be avoidable by infants until after their majority. Infants may possess property, but it must be under the management and control of a guardian. They have not the right of citizens as to voting and discharging other political functions. But in regard to crimes and punishments, and trespasses and private wrongs, their conduct is regulated by the same laws as that of the other members of the community, in case of their being of sufficient age and discretion to understand their duties and obligations. And for this purpose no general limit can be assigned, as some children are much more intelligent than others of the same age; and it will again depend, in some degree, upon the nature of the offense committed, or the wrong done, whether a child of any given age can be considered legally guilty of it, since some offenses and wrongs can be more easily understood to be such than others. The law, in general, has a tender regard to youth, and does not permit them to be convicted and punished for offenses and trespasses unless it appears clearly that they have sufficient knowledge and discretion to distinguish them to be such. There are exceptions to the incapacities of minors as to contracting, and these exceptions are made for their benefit. Thus an infant not sufficiently furnished with necessary clothes, food, lodging, medical services, or instruction, by his parent or guardian, and not being under the immediate superintendence of the parent or guardian, may make a valid contract, in respect to those subjects, and such contract may be enforced against him. However, an infant who has contracted for and received necessaries is liable for their reasonable value only, and not necessarily for the agreed price. Infants require the consent of parents or guardians to marry. The jurisdiction in respect to infants is generally vested in either probate or orphans' courts. These courts appoint guardians to take charge of the property of infants, and, in case of the decease of the father, to take charge of their persons; but during the life of the father he ordinarily has the guardianship and control of the persons of his children until they are 21 years of age.

Blackstone thus treats the subject infant: "Infants have various privileges, and various disabilities; but their very disabilities are privileges, in order to secure them from hurting themselves by their own improvident acts. An infant cannot be sued but under the protection and joining the name of his guardian, for he is to defend him against all attacks as well by law as otherwise; but he may sue either by his guardian, or by his prochein ami, or alone for wages in the county courts. In criminal cases an infant of the age of 14 years may be capitally punished, but under the age of seven he cannot. The period between 7 and 14 is subject to much uncertainty; for the infant shall,

generally speaking, be judged *prima facie* innocent; yet if he was *doli capax,* and could discern between good and evil at the time of the offense committed, he may be convicted, and undergo judgment and execution of death, though he has not attained to years of puberty or discretion."

INFANT JESUS, Daughters of the Congregation of the, is an order in the Roman Catholic Church. It owes its origin to Anna Maroni a native of Lucca, who having come to Rome entirely destitute, succeeded by her industry in securing a competency. In more advanced years, her charitable feelings prompted her to establish an institution where poor girls should be instructed in such work as would enable them to earn a livelihood. The clergy approved of her plan, and afforded her much assistance, and it was finally established as a regular institution. In 1673 Pope Clement X acknowledged the existence of the society, gave it by-laws, and endowed it with sundry privileges, under the appellation of "Daughters of the Infant Jesus." The number of the "Daughters" allotted to each convent was fixed at 33, in commemoration of the number of years Jesus lived upon earth. The novitiate lasts three years; the sisters make vows of poverty, chastity and obedience. Such as may wish to leave the convent are allowed to do so before taking the vows, but in that case, they are to leave to the convent all they brought to it at their admission. Prayers and fasts are strictly enforced. The regular habit of the order consists of a wide, dark brown dress, and a white hood.

INFANT MORTALITY. See VITAL STATISTICS.

INFANT SCHOOL. See EDUCATION; FROEBEL; KINDERGARTEN.

INFANTE, José Miguel, Chilean statesman: b. Santiago de Chile, 1778; d. 1844. He took part in the War of Independence in 1810 and subsequently served as president of the Junta. 1817 he was dispatched as special envoy to Argentina. He always acted from pure and disinterested motives, refusing public office whenever he felt that conditions were safe without him, and opposing the granting of arbitrary authority to individuals. He founded *El Valdiviano Federal* in 1821 and remained its editor until his death. Many progressive measures were sponsored by him, notably the emancipation of the slaves and the founding of the Chilean educational system. He was offered the post of Chief Justice of the Supreme Court in 1843 but declined to serve.

INFANTE, Spanish title of all princes of the blood royal with the exception of the heir to the throne, who is styled El Principe de las Asturias. The title is also bestowed on consorts of royal princesses and was used similarly in Portugal before that country became a republic.

INFANTICIDE, the murder of a child born alive, is a crime of frequent occurrence. The main cause of the crime is shame, induced by a dread of the social disgrace attaching to mothers of illegitimate children; though in many instances infanticide has been the result of violence produced by puerperal insanity. The morbid disposition to kill the newly born has also been observed in certain of the lower animals. The sanctity of human life, from its beginning to its close, is a maxim of modern civilization, and the law treats as a murderer whoever wilfully terminates it at any stage. According to the law of England every woman who employs means to procure criminal abortion is guilty of felony, and liable to penal servitude for life, or not less than three years; and severe penalties are inflicted on those who aid women to procure miscarriage. The concealment of birth is a misdemeanor, and may be punished with imprisonment for two years. In the United States, when a child's death is occasioned by an illegal act, such act is considered either murder or manslaughter according to the circumstances. The crime, however, is rarely punished, and in large cities many cases occur each year which are never reported to the authorities.

Infanticide was prevalent in Greece and Rome. In modern times many barbarous peoples are guilty of wholesale child-murder. Among some of the Pacific Islanders and aboriginal Australians there is a great destruction of infant life. The Hindus used to destroy female children without compunction. In China infanticide is said to be very common. See ABORTION.

INFANTILE PARALYSIS. See POLIOMYELITIS.

INFANTRY, name given to soldiery serving on foot and using small arms and equipped for marching and fighting on foot. Modern combat demands the highest order of training, discipline, leadership and morale on the part of the infantry. Modern war requires but one kind of infantry—good infantry—and this must take the offensive to gain decisive results. In the local combats which make up the general battle the better endurance, use of ground, fire efficiency, discipline and training will win. It is the duty of the infantry to win the local successes which enable the commanding general to win the battle, and it must have the tenacity to hold every advantage gained, the individual and collective skill needed to master the enemy's fire, the determination to close with the enemy in attack, and to meet him with the bayonet in defense. It must be trained to bear the heaviest burdens and losses, both of combat and march.

Among the ancient nations of Europe, infantry or foot soldiers constituted the chief strength of armies. In the days of the Grecian and Roman states, battles were won mainly by the force and discipline of the phalanges and legions, and the number of the infantry in the field far exceeded that of the cavalry. The cavalry were then, as at present employed chiefly in protecting the wings of the army, and in completing a victory gained by the infantry. The ancient Franks, when they left the forests of Germany, were accustomed to march and fight on foot; and they persevered in this practice even after they had obtained possession of the country of the Gauls, which abounded with horses. But soon after the time of Charlemagne, institutions of chivalry were generally adopted in the kingdoms of Europe. These led to frequent exhibitions of martial exercises on horseback in presence of the sovereigns and assembled nobles; and the interest inspired by the achievements of the knights on

those occasions was naturally followed by a high regard for that order of men. By degrees the cavalry, which was composed of persons possessing rank and property, and completely armed, acquired the reputation of being the principal arm, while the foot-soldiers, badly armed and disciplined, were held in comparatively small estimation. This continued 400 years, and although war was the principal occupation of mankind, military science fell into neglect. But rulers were forced by the power of feudalism to make an alliance with the despised class of foot-soldiers, and in 1214 we find that some of the German infantry was recognized to be "very good and trained to fight even against cavalry." The cavalry of France was routed at Courtrai by the infantry during the next century, and the Austrians suffered defeat by the efficient work of the Swiss pike at Morgarten (1315), Sempach (1386) and Nafels (1388). At Cressy and Poictiers (1346–56), the knights of England dismounted to fight beside the successful infantry. The principal weapons of the infantry before the invention of gunpowder were longbows, halberds, cross-bows, spiked clubs, axes, pikes, straight-swords, shields, corselets, mail-jackets, helmets and partisans. In the 16th century, however, these weapons were replaced by firearms, and in the 18th century, the musket was in general use. It became customary during the Thirty Years' War to form battalions of infantry composed of 500 men, which were massed into dense columns during battle in spite of the deadly effect of the enemy's artillery. The absurdity of this formation was first exposed by Gustavus Adolphus, who recognizing the destructiveness of firearms, arranged his battalions with a view to increasing the effectiveness of the fire of his troops, while avoiding exposure to that from the enemy. His tactics were so successful at Breitenfeld and Lutzen (1631–32) that they were soon afterward universally adopted. Frederick the Great made many improvements till then comparatively unknown. The rapidity with which his infantry troops performed their evolutions during battle contributed largely toward his famous victories in the Seven Years' War. In fact the Prussian infantry have ever since his time served as models for other European countries. The superiority of this arm consists in the troops being able to act on ground which cavalry cannot, and it is obvious that the latter must be nearly useless in the attack on fortified towns.

Co-operation with Other Arms.— The attack of intrenchments is hopeless without the aid of artillery. With reference to the amount of artillery to be used, the opinion is general that there cannot be too much. Artillery and infantry without modern equipment exist only in name.

The infantry should designate objectives for the artillery, since it is this arm that appreciates the danger points and knows definitely where fire should be directed. The eyes of the artillery are the observers, who should be with the infantry in the trenches. The artillery should place the guns where it pleases but the commander and the observers, the brain and the eyes, must preserve the most intimate contact with the infantry. The attacking infantry requires two things: (1) To know where to go and to see how to go; (2) to receive the greatest possible assistance from the artillery before, during and after the assault. The most dangerous period of all for the attackers is after the position is taken when the enemy concentrates his fire upon it and makes a counter assault. Surprise action by concentrated artillery fire is to be sought. The maximum effect in the shortest period of time should be striven for, as this naturally renders the surprise more complete.

It is a grave mistake to try to fix in advance the time of duration of the artillery fire. The fire should continue until in the opinion of the commander of the attacking force, it has accomplished its purpose. When the infantry advances to the assault the artillery protects it with a curtain of fire to the front and both flanks.

To guarantee a close co-operation between the artillery and its own infantry, artillery officers should accompany the advanced infantry lines. The infantry commander has not always the time to communicate to the artillery observer everything that is wanted from the artillery. The observer, by reason of his technical knowledge, can be of great assistance in advising the infantry commander as to the best methods to pursue to bring about effective artillery support. But in order to carry out a mission of this kind, the observer should have a thorough knowledge of the details of the infantry combat to appreciate what is happening around him.

Infantry Machine Guns.— Three machine gun platoons form a part of each regiment of French infantry. In order to avoid premature exposure to hostile fire the platoon advances under cover to a position for unpacking, from which the guns, after being prepared for action, are carried forward to a position in readiness. Great care in reconnoitering and taking up the firing position is enjoined, in order that the position of the guns may not be disclosed.

The regulations recognize three methods of fire: *Distributed fire,* the normal method, which calls for sweeping the designated target from flank to flank with 100 rounds once or twice; *continuous fire,* in which the fire continues until interrupted from time to time by the chief of piece as the target disappears momentarily; and *unit fire,* which is delivered by using the gun substantially as a rifle, thus stimulating rifle fire and preventing the premature disclosure of the presence of a machine gun.

Normally only one of the two guns of the platoon is fired. Firing with both guns at the same time is exceptional and is justified only against a particularly threatening portion of the hostile force; that is, against a deep, broad and only momentarily visible target.

Machine guns are a valuable aid to infantry engaged at close ranges. They are to be regarded as a movable fire reserve. In order that they may be concentrated at the time and place at which fire superiority becomes essential, they should not be put into action prematurely.

The machine gun is valuable mainly at short and mid ranges, and becomes especially effective when it may be used in enfilading a line or in rolling up a flank. Its value is comparatively small against a target of little depth or a line with great intervals.

Machine guns are placed to the best ad-

vantage immediately in rear of a flank or in rear of intervals in the most advanced line. To fire over infantry or other troops by way of supporting them is to be thought of only when the terrain renders possible two or more lines of fire, one above the other.

Infantry Attack.— In the operations before Verdun, the German army corps nearly always attacked with their divisions side by side. Only in exceptional cases, as when the extent or importance of the zone assigned to a single corps permitted only the employment of a single division, did the other remain behind in support of the first.

The front of the zone assigned to a division of three regiments (7,200 rifles) varies between 1,000 and 2,500 meters, according to the importance and number of the successive objectives assigned to it.

In respect of the disposition for attack of its units, if the zone of action be narrow and the objective varied, the division places two regiments in the first line, side by side, with the third in reserve. But if the zone be wide, with only one objective, then the three regiments form in one line, separated by intervals varying with the nature of the ground.

Whatever be the disposition taken by the division, the regiments place in general one battalion in the first line and keep two in reserve, echeloned in depth at distances depending on the nature of the ground. The more advanced of the two reserve battalions is always in readiness to advance, either to support the attack against the first objective, or to carry it on beyond. The other reserve battalion is at ease; its duty is, at the right moment, to relieve the exhausted units of the first line.

The German infantry in general turns out its battalions in two lines. The first is almost invariably composed of two companies side by side; these deploy for the assault either in the most advanced trench or in the last shelter. The second line remains in the supporting trenches either in shelters or under some covering obstacle.

The procedure of attack is always that of successive lines of men, and rests upon the following general principles:

1. To each line of attack is always assigned a limited and well-defined objective, no wider than the front of attack, and never deeper than the distance between two successive lines of trenches.

2. The assaults open only after the artillery has thoroughly swept the trenches and destroyed the obstacles, in order to compel the defense to abandon all idea of resistance.

3. The assault proper is preceded by thorough reconnaissance of the objective sought, in order to make sure that the artillery has produced the desired effect. These reconnaissances in reality constitute the first wave of the assault; the succeeding waves are held back until the first shall have made progress.

In respect of details, the various methods of assault are more or less of the following pattern: the successive waves are three, separated by some 20 or 30 paces. The first of these makes the reconnaissance mentioned above, it is formed by one or two squads from each platoon, is accompanied by scouts carrying tools, and by grenadiers, and is deployed at wide intervals. The second wave consists of a dense line of rifles, and comprises the principal part of each platoon. This line's duty is to occupy the trenches. Finally, the third is composed of the remainders of each platoon, and constitutes a new echelon, whose business it is to fill the gaps that may be produced. With it goes a reserve of munitions and materials in order to hold the captured trenches.

Infantry Against Cavalry.—A cavalry charge can accomplish little against infantry, even in inferior numbers, unless the latter are surprised, become panic-stricken, run away, or cannot use their rifles. A charge from the front is easily checked by a well-directed and sustained fire.

If the charge is directed against the flank of the firing line, the supports, reserves, or machine guns should stop it. If this disposition is impracticable, part of the line must meet the charge by a timely change of front. If the cavalry line passes through the firing line, the latter will be little damaged if the men retain their presence of mind. They should be on the watch for succeeding cavalry lines and leave those that have passed through to friendly troops in rear.

In a mêlée, the infantryman with his bayonet has at least an even chance with the cavalryman, but the main dependence of infantry is rifle fire. Any formation is suitable that permits the free use of the necessary number of rifles. Ordinarily there will be no time to change or set sights. Fire at will at battle sight should be used, whatever the range may be. It will usually be unwise to open fire at long ranges.

An infantry column that encounters cavalry should deploy at once. If attacked from the head or rear of the column, and if time is pressing, it may form a succession of skirmish lines. Infantry, by deploying 50 or 100 yards in rear of an obstacle, may check cavalry and hold it under fire beyond effective pistol range. In any situation, to try to escape the issue by running is the worst and most dangerous course the infantry can adopt.

In attacking dismounted cavalry, infantry should close rapidly and endeavor to prevent remounting. Infantry which adopts this course will not be seriously checked by delaying cavalry. Every effort should be made to locate and open fire on the led horses.

Infantry Against Artillery.—A frontal attack against artillery has little chance of succeeding unless it can be started from cover at comparatively short range. Beyond short range, the frontal fire of infantry has little effect against the artillery personnel because of their protective shields. Machine guns, because their cone of fire is more compact, will have greater effect, but on the other hand they will have fewer opportunities and they are limited to fire attack only. As a rule, one's own artillery is the best weapon against hostile artillery.

Artillery attacked in flank by infantry can be severely damaged. Oblique or flank fire will begin to have decisive effect when delivered at effective range from a point to one side of the artillery's line of fire and distant from it by about half the range. Artillery is better protected on the side of the caisson.

Guns out of ammunition, but otherwise secure against infantry attack, may be immobilized by fire which will prevent their withdrawal, or by locating and driving off their limbers. Or they may be kept out of action by fire which will prevent the receipt of ammunition.

Artillery when limbered is helpless against infantry fire. If caught at effective range while coming into action or while limbering, artillery can be severely punished by infantry fire. In attacking artillery that is trying to escape the wheel horses are the best targets.

Trench Warfare.— In the present warfare, trenches play a most important rôle, and in order to obtain success, it is necessary to employ only infantry which is morally fit and thoroughly trained. The two factors, "*fire action and advance*" have been recognized by all belligerents as not having the same meaning as heretofore. Success will not be brought about by these two factors alone, on account of the extensive use of obstacles. In order to win, the infantry attack must be preceded and must be accompanied by powerful means of destruction, such as fire action in all of its forms, grenades, mines, aerial torpedoes, asphyxiating gases and burning liquids. During the *advance*, the attacking lines are confronted with three kinds of powerful obstacles: barbed wire entanglements, machine guns and the artillery curtain of fire.

The French tactical unit is the infantry division. Every military movement demands that the division be complete in itself. It should have heavy artillery, field artillery and trench artillery. Under the classification of trench artillery are included cannon of less than 7.5 mm. calibre, or those having a shorter range than the present field pieces.

No definite rules can be laid down for trench warfare. New lessons are being taught, and each belligerent is constantly changing his methods of warfare, at least in the manner of execution. There is no greater mistake than to undertake attacks, the necessity of which has not been clearly demonstrated.

The attack on an enemy's trench should never be undertaken except after a careful study of the situation; but, once launched, the objective must be gained, with the minimum amount of losses and with this one idea in mind, of holding the ground captured. The assault must be of short duration. It cannot be so, unless the attack has been well prepared, well arranged, and every detail attended to beforehand. Between any advantage that may be gained through surprise, which is not possible in trench warfare, and a careful preparation by the supporting artillery just before the attack, the latter method is preferred by the infantryman. To attack blindly a line of trenches is a thing of the past. To believe that if the difficulties of an attack are known to the infantry, its offensive spirit is reduced, is nothing but a fallacy. See ARTILLERY; CAVALRY.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

INFANTRY, Mounted, soldiers trained to act as foot and cavalry soldiers and usually equipped with rifles from which fact they are frequently designated mounted riflemen. Their supreme advantage over ordinary infantry consists in their greater mobility. This arm is but little known at present, but was favored by many expert soldiers during the American Civil War and the following decades. In the struggle between the North and South the so-called cavalry was little better than mounted infantry, all their training being along the lines laid down for the latter. Mounted infantry appear to have been first introduced by Marshal de Brissac in 1600. In 1672 they were introduced into the British army. Napoleon I and his generals appreciated the possibilities of this arm. In the 19th century the value of mounted infantry for outpost duty, for covering retreats, for sieging, holding or destroying bridges, and for other works of destruction, such as removing telegraphs, etc., were generally recognized. In this way this arm rendered efficient service in the Civil War. The chief action of such troops must always be as infantry, the horses of the dismounted men being held by their comrades. Mounted infantry differ essentially from cavalry, the latter depending little or not at all on fire-arms, but almost entirely on lance or sabre and the shock of the charge. Mounted infantry on the other hand, depend on the rifle and their mounts are merely intended to give them a maximum degree of mobility. The introduction of aircraft in modern armies has dispensed in great part with mounted troops for purposes of reconnaissance, and motor transport is being increasingly used for the rapid transfer of troops to points where the line is hard pressed. Modern trench warfare, also, has to a very great extent eliminated all mounted troops. It is too early, however, to draw general conclusions from the Great War of 1914–18, in which mounted troops played but a small part after the first few weeks of open fighting.

INFECTION, the introduction of disease-producing micro-organisms in the body. Infection may result in a number of different ways. Micro-organisms may be introduced by means of direct injury. When a person falls and cuts the hand, the bacteria of pus-production or of tetanus may be so introduced, and blood poisoning or tetanus may develop. Many infections come by means of the intestinal tract. Thus typhoid is commonly obtained from milk or drinking-water. The intestinal worms, tapeworm, roundworm, are contracted in this manner, and a number of other parasites, particularly the trichina, may come from infected food taken into the alimentary canal. Infection may also occur by means of the air-passages. The bacillus of tuberculosis is most often taken into the body in this way, and finding suitable soil, it causes the development of the dread disease. The bubonic plague is frequently contracted through the disease-germ entering the air-passages. At the present time it is deemed not unlikely that a number of infectious diseases, notably influenza, diphtheria, scarlet fever, measles, whooping-cough, are contracted through the respiratory tract by infection with the exciting cause. Occasionally direct contact seems necessary for infection, as in gonorrhœa and

syphilis. In malaria, and probably in yellow fever, the active agent that causes the disease is introduced into the body by the bite of an insect, the mosquito. In malaria one particular genus (*Anopheles*) serves as an intermediate host in the developmental history of the parasite, in a manner analogous to the history of the development of a number of the intestinal worms. It is not unlikely that a large number of diseases may be disseminated by the bites of insects of one kind or another. In all the infectious diseases the element of a real, live, and active contagion should never be overlooked. Infectious diseases do not spring out of nothing. There must be some sort of contact in order that a person become infected. A most important part of the treatment of all infectious diseases is the protection of other people by proper care of all one's own excretions during sickness. The doctrine so frequently taught by some that sickness is ignorance is an important half-truth. But for the ignorance of people concerning the proper care of those afflicted with infectious diseases with reference to the protection of others, measles, diphtheria, scarlet fever, whooping-cough, typhoid fever, consumption, and a number of other maladies would be entirely eradicated from civilized communities.

INFERENCE, the mental process of deriving a new judgment from certain premises or assumptions. It is a familiar fact that the mind passes naturally from given facts to more or less assured conclusions based upon them, as when we expect that rain will follow a change in the appearance of the sky. When such mental transitions become explicit so as to be susceptible of being arranged as a series of propositions, we have inference. Inference is more or less experimental, and therefore subject to test by certain rules with regard to its correctness. See DEDUCTION; FALLACY; INDUCTION.

INFERNO. See DIVINE COMEDY, THE.

INFIDEL, in modern parlance, one who deliberately rejects the Christian faith after obtaining knowledge of it. In former times a man might be an infidel who had never heard of Christianity. *Infidelis* in ecclesiastical language means "unbelieving," and is applied to unevangelized heathen as well as doubters and apostates. Thus in the Roman Catholic Church a bishop *in partibus infidelium* merely means a bishop whose diocese is set in heathen countries.

INFINITE SERIES. See SERIES.

INFINITESIMAL CALCULUS. See CALCULUS, INFINITESIMAL.

INFINITIVE, the indefinite mode in which the verb is represented without a subject. As the verb expresses an action, or a state, it generally belongs to a subject whose action or state is expressed; but if we wish to express the mere idea of this action or state we use the infinitive, which, therefore, in many languages is employed without further chance as a substantive — for instance, in Greek and German — only preceded by the neuter article; but as the verb expresses an action or state under certain conditions of time, the infinitive can also express the action or state in the present, past, or future, though these conditions are not expressed in all languages by peculiar forms. Some languages express it by some grammatical contrivance, as is the case in English, where it is denoted by *to* prefixed to the general uninflected form of the verb, as *to love* = Latin *amare; to have loved* = Latin *amavisse*. The infinitive may be regarded as the point of transition from a verb to a substantive, and is often used as the subject of a proposition.

INFINITY, a notion which has assumed the most varied forms, characterized by few common characteristics except the transcendence of our customary notions of boundedness and limit. The chief types of infinitude which come to the attention of the mathematician and philosopher are cardinal infinitude, ordinal infinitude, the infinity of measurement, the ∞ of algebra, the infinite regions of geometry and the infinite of metaphysics.

Cardinal infinitude pertains to assemblages and only to assemblages. An assemblage is finite if it can be exhausted by taking member after member from it. It is what is called reflexive if it can be paired off in a one-one manner with a class derived from it by the removal of one term. Whether all non-finite classes are reflexive is not known, as all supposed demonstrations of this statement rest in the insecure basis of Zermdo's axiom. (See ASSEMBLAGES, GENERAL THEORY OF). The set of all classes which can be paired off in a one-one manner with a given class or assemblage is known as a cardinal number. The cardinal numbers of reflective classes are known as transfinite cardinal numbers. Reflective classes are perfectly definite and bounded, though their manner of limitation is not susceptible of being based on an enumeration, as is the case with finite classes.

Ordinal infinitude is a property of well-ordered series. A series is an order which establishes a definite and unique precedence between any two terms which it concerns, and which is such that if it makes *a* precede *b* and *b* precede *c*, it makes *a* precede *c*. A series is well ordered if every series generated by an operation included in its ordering operation has a first term. A well ordered series is infinite if it contains a cardinally infinite number of terms. Two well ordered series are ordinarily similar if their terms can be put in a one-one correspondence in such a manner that corresponding terms always bear the same relation of precedence or succession to corresponding terms. An ordinal number is the set of all well ordered series similar to a given series. It is transfinite or infinite if it is the number of an infinite series.

Infinitude enters into a system of measurement in two different ways: as infinitude of subdivision and as infinitude of distance. A scale of measurement is a system of entities such that every pair has a corresponding real number, which is regarded as the distance separating the members of the pair. The infinite divisibility of a distance is the fact that the distance can be regarded as the sum of a chain of distances stretching from one point to the other, and of as small a magnitude as may be desired. This is preconditioned by the fact that between every two real numbers there lies another real number. The infinite extent of a system of measurement consists in the fact that starting from any point it is possible to find another point removed from it by a distance of arbitrarily great magnitude.

Strictly speaking, the symbol ∞ has no meaning except in some such context as $f(\infty)$. $f(\infty)$ is an abbreviation for the limit of $f(x)$ as $|x|$ increases without limit, and is only significant when $f(x) - f(x')$ can be made arbitrarily small if $|x|$ and $|x'|$ are only chosen larger than some number A. $f(\infty)$ may also be written $\lim_{x=\infty} f(x)$. $f(+\infty)$ or $\lim_{x=+\infty} f(x)$ means the limit of $f(a + ib)$ where a and b are real and a increases through positive values without limit. $f(-\infty)$ and $\lim_{x=-\infty} f(x)$ have the analogous meaning. $f(+\infty)$ and $f(-\infty)$ may exist when $f(\infty)$ is meaningless.

In ordinary Euclidean geometry parallel pairs of lines and intersecting pairs of lines exhibit many important analogies. The convenient expression of these is rendered possible only by the adjunction to the ordinary points, lines and planes of certain entities, called points, lines and planes at infinity. The method of this adjunction differs in the several mathematical disciplines, for it is dictated by considerations rather of convenience than of logical necessity. In solid projective geometry (q.v.) the adjoined points form a plane cutting every ordinary line or space in one point. This enables the universal law to be formulated, that every two lines intersect in one point, and only in one point. In the theory of the functions of a complex variable (q.v.), on the other hand, it is much more convenient to regard the entire infinite region as a single point, lying on every line.

The infinite of philosophy, corrupted though it is with much undigested and misunderstood mathematics, contains a motive of its own. It is that which lacks external relation, not merely in so far as it is of a spatial, temporal or numerical character, but in any manner at all.

The idea of the infinite is as old as the Ionian philosophy, when Anaximander (610 B.C.) declared that the one in the many, the basis of being in Nature, was *το ἄπειρον*, the infinite. The reality of infinitude has been the source of much controversy, and the tendency of many modern philosophers is to deny it, for there is unquestionably a difficulty in the entrance of the unrelated into the cognitive relation. The discursive nature of knowledge makes us bring every object into a context. This difficulty of finding a context for the infinite is the basis of those antinomies of Kant (q.v.) which concern it. "An infinite number," says Bosanquet, "would be a number which is no particular number, for every particular number is finite. It follows from this that infinite number is unreal." On the other hand F. H. Bradley states the contrary, in the clearest terms, "We may be asked whether Nature is finite, or infinite. . . . if Nature is infinite, we have the absurdity of a something which exists; and still does not exist. For actual existence is, obviously, all finite. But, on the other hand, if Nature is finite, then Nature must have an end, and this again is impossible. For a limit of extension must be relative to an extension beyond. And to fall back on empty space will not help us at all. For this (itself a mere absurdity) repeats the dilemma in an aggravated form. But we cannot escape the conclusion that Nature is infinite. And this will be true not of our physical system alone, but of every other extended world that can possibly exist. . . . Every physical world is, essentially and necessarily, infinite."

It seems as if Aristotle had a clearer and more logical view of infinity, *το ἄπειρον* than many moderns such as Bosanquet. He says, *λείπεται οὐν δυνάμει εἶναι το ἄπειρον*. He means of course, that, with regard to finite human intelligence, the infinite remains unrealized, although logically it could be realized, and of course, when we speak of infinite time, or infinite creative change in nature, we speak of something which potentially exists, but is only gradually becoming actual. In other words, we can transcend whatever relations we choose, so long as we do not transcend Relation.

Professor Royce of Harvard has undertaken the task of vindicating the concept of the actual Infinite against the charge of self-contradiction. He is controverting Mr. F. H. Bradley of Oxford, who while he admits "we cannot escape the conclusion that Nature is infinite," expresses also his belief that such an assertion is a contradiction in terms. Professor Royce attempts to accomplish this vindication by proving the following theses:

1. The true Infinite, both in multitude and in organization, although in one sense endless, and so incapable in that sense of being completely grasped, is in another, and precise sense, something perfectly determinate. Nor is it a mere monotonous repetition of the same, over and over. Each of its determinations has individuality, uniqueness and novelty about its own nature.

2. This determinateness is a character which, indeed, includes and involves the endlessness of an infinite series; but the mere endlessness of the series is not its primary character, but simply a negatively stated result of the self-representative character of the whole system.

3. The endlessness of the series means that by no merely successive process of counting, in God or in man, is its wholeness ever exhausted.

4. In consequence, the whole endless series, in so far as it is a reality, must be present, as a determinate order, but also all at once, to the absolute experience. It is the process of successive counting, as such, that remains, to the end, incomplete, so as to imply that its own possibilities are not yet realized. Hence, the recurrent processes of thought reveal eternal truth about the infinite constitution of real Being,— their everlastingly pursued Other; but themselves,— as mere processes in time — they are not that Other. The true Other is, therefore, that self-representative system of which they are at once portions, imitations and expressions.

5. The Reality is such a self-represented and infinite system. And herein lies the basis of its very union, within itself of the one and the many. For the one purpose of self-representation demands an infinite multiplicity to express it; while no multiplicity is reducible to unity except through processes involving self-representation.

6. Nevertheless, the Real is exclusive as well as inclusive. On the side of its thought the Absolute does conceive a barely possible infinity,

other than the real infinity, a possible world, whose characters, as universal characters, are present to the Absolute, and are known by virtue of the fact the Absolute thinks.

The Royceian theory of the infinite is based on the analogy of cardinal infinitude, and presupposes that there is such a thing as a complete universe. Certain paradoxes discovered by Russell and Burali-Forti tell very strongly against the existence of a complete unity embracing all lesser unities. Royce's work possesses value rather as an account of the potential infinity of a universe capable of indefinite enlargement than as a description of a given, complete infinite. Furthermore, it is clear that systems of much less extent than the Royceian infinite may possess the self-reflecting property of cardinal infinity. (See ASSEMBLAGES, GENERAL THEORY OF). NORBERT WIENER,
Editorial Staff of The Americana.

INFLAMMATION, a term long used to indicate the phenomena that follow mechanical, chemical or physical injuries to living tissues. These changes have been described for centuries as rubor (redness), calor (heat), dolor (pain) and tumor (swelling), which are the phenomena particularly seen on surface inflammations. At the present time the idea is becoming fixed that inflammation is a conservative process, the phenomena attending nature's effort to rid the tissue of harmful substances. In the normal process of repair of an injury there are changes which closely resemble the milder types of inflammation; but when to a mechanical, chemical or physical injury there is added a growth of micro-organisms, the reply on the part of the body-cells differs from the ordinary repair of injury. The changes witnessed depend upon the strength and kind of invading micro-organism and the particular tissue invaded. The first change is *hyperæmia,* a suffusion of the part with blood from capillary dilatation; following this the liquid part of the blood, the serum, is poured out into the tissues and offers its resisting powers to the poisonous substance. If these measures be insufficient, the white blood-cells called phagocytes congregate in the tissues, destroying the invading organisms, by actually consuming them and neutralizing their toxic products. During this struggle there is more or less death of the cells, called "degeneration"; large masses "slough"; the remnants of the cells and the phagocytes killed form the thick fluid called pus. When an inflammation goes on to the formation of pus, it is spoken of as *purulent* or *suppurative.* Certain poisons cause a peculiar reaction on the part of the tissues, characterized by the formation of new tissue that is unable to carry on the function of the part. This tissue is the same as the connective tissues, and the process is called *productive inflammation.* The poisons that continue to act for a long time are particularly apt to cause this reaction, and the inflammation is called *chronic* because of its permanency. Catarrhal inflammations are these same processes when they occur in mucous membranes; the appearance of these catarrhs, however, is different, owing to the peculiar structure of mucous membrane and to the fact of the epithelial covering offering excellent resistance to invasion. When death of cells occurs they can readily be cast off. Croupous inflammation is the term used to describe those in which there is considerable destruction of the superficial layers of the mucous membrane, which, with the fibrin of the blood, forms a coating or "false membrane" on the surface. Granulation tissue (q.v.) is the name applied to the tissue formed during the repair of an injury. Names are given to certain types of inflammation having a characteristic appearance to the naked eye, but microscopically there is nothing absolutely distinctive in these except their arrangement. Particular examples of these are tubercular and syphilitic inflammations.

The majority of the diseases of the body that we recognize as entities are due to inflammation in some tissue or organ, but the picture depends on the various changes in the functions of different parts of the body. The kind and virulence of the generated poison, together with the reaction on the part of the body-tissues, makes the complete picture that we seek to recognize. The treatment of inflammation is, in large part, the practice of medicine and surgery. Efforts to help the tissues combat against invasion are made with more success as knowledge is gathered of the peculiar invading forces and the natural modes of defense. It is not that we wish to combat the inflammation *per se,* but rather to make it unnecessary by helping it to a successful issue. The actual destruction of the bacteria by drugs introduced into the body is of little use, for they would be apt to cause as much destruction of the body-cells as of the invading cells; but their toxines, which cause the actual damage, we are learning to neutralize by the administration of artificially prepared antitoxins, and by placing the body and its special tissues under the most favorable conditions for developing its natural forces of resistance.

In exposed parts of the body, where antiseptics may be applied, the toxic germs may be killed, and various measures that change the blood-supply may be advantageous. Where death of tissue takes place, nature may require help in its removal. It has long been the rule to evacuate pus wherever it is formed, unless its escape from the tissues is easy.

The treatment of chronic inflammation is entirely different, as this is a process where actual structure is changed beyond repair in many instances. The all-important question is whether the tissue can carry on its proper functions; for if it can, the body need not suffer. The inflammatory process is arrested in its progress by the removal of the irritating cause, by improving the blood-supply of the part and the vitality of the body generally. These constitute the measures in general applied for the cure of chronic inflammations, it being understood that the endeavor is to place the tissues in such a condition that they may carry on their functions for the good of the whole organism; and the failure of these measures shows either that they are at fault or that the tissue-change has gone too far. Inflammation of any part is indicated by adding the suffix "itis" to the name of the organ or tissue. (See BRONCHITIS, COLITIS, LARYNGITIS, MENINGITIS), etc. Consult Delafield and Prudden, 'Textbook of Pathology' (9th ed., New York 1911), and Smith, A. H., 'Intermediate Inflammatory Process' (in Transactions of the Association of American Physicians' (ib. 1900).

INFLAMMATION OF THE LUNGS. See PNEUMONIA.

INFLECTION. See INFLEXION.

INFLEXION (Latin, *inflexio,* a bending), that process in grammar which modifies words when placed in relation to other words in a sentence; the act or process of varying the form of words, as by altering the endings or suffixes, so as to express grammatical relationship. It was primarily called bending, evidently because the word was bent to a new shade of meaning. It includes both declining and conjugation, and it is interesting to note that declining also carries out this same idea of bending down the word. In the grammatical term "case," from the Latin *cado,* to fall, there is also the same idea of falling away. Hence, it is well to regard inflexion, in grammar, as the allowing of a word to fall away in a different manner to express some relationship. We say "I love," "he loves," "I am loved" and sometimes "thou lovest." In each case the fundamental idea of love is the same, but the ending on inflexion is bent to agree and harmonize with the noun. In the case of nouns, pronouns and adjectives, we call this process *declension,* and this term was once also used for verbs, but has been displaced by *conjugation.* Nouns and their adjectives should agree in gender, number, person and case. In primitive speech it is obvious that men talked largely by nouns, mainly of one syllable, for the most common things are thus named, viz.: eye, ear, arm, leg, nose, knee, axe, bow, box, tree, hole, sun, moon, etc. Then came longer nouns, as house, elbow, throat, breast, arrow, etc. Then came words of action, the verbs. Qualifying words followed, now known as adjectives and adverbs. Then came joining words, the conjunctions, prepositions and articles. The next step in the development of language was obviously the showing of relationship. As expressions of gender, came "he," "she" and "it"; adding s came to show the plural in most cases; the person, as present or objective, was suggested by "I" and "you"; the case is illustrated by "thou" (nominative), "thine" (possessive), and "thee" (objective).

To conjugate means primarily to join in couples or pairs, but it has been extended in meaning "to state the principal parts of a verb." Conjugation is a connected process of giving the entire series of inflexions of a verb, that is, all its forms in person, number, mode, tense and voice. Many conjugations seem tedious and unnecessarily prolix, but other languages may be more difficult in this respect, as Arabic, in which verbs have 15 conjugations, in theory if not always in practice. In English the common auxiliary verbs am, do, have, shall, will, may, can, asserting respectively existence, action, possession, obligation, volition, liberty, power, assume the function of inflexions and are themselves inflected to denote past time. In French the same inflexional law exists, the connection between the auxiliary and the root being closer than in English. *Aimer-ai,* I have to love, that is, I shall love, is compounded of the infinitive *aimer,* to love, and *ai,* I have, the first person present indicative of *avoir.* The same is the case in Italian and Spanish.

Pronominal and predicative roots are combined to form one word in the Semitic and Aryan tongues, which are therefore called inflexional, a process impossible in monosyllabic languages like the Chinese or in languages of the agglutinate order like those of the Turanian family. The Semitic and Aryan families of languages, which admit of phonetic corruption both in root and the terminations, are called organic or amalgamating languages. The pronominal termination varies according to the person or number. Thus the Sanskrı *mi, si, ti,* the endings of the three persons singular of the present of the verb, are perhaps from the personal pronouns *ma, sva, ta* and the persons of the plural indicate the plural number by the form of the pronominal affixes. The plural of masculine and feminine Greek and Latin nouns of the third declension is probably a contraction of the duplication of *sa,* the pronoun of the third person. See GRAMMAR.

INFLUENCE OF THE WAR ON LITERATURE, ART AND MUSIC. See LITERATURE, ART AND MUSIC, INFLUENCE OF THE WORLD WAR ON.

INFLORESCENCE, INFRUCTESCENCE, botanical terms referring respectively to methods of flowering and fruit-bearing. The flowering shoot, says Strasburger, frequently bears only a solitary, either axillary or terminal flower. In many cases, however, the metamorphosis of the generative region, which results in the production of flowers, has led to the formation of a special system of fertile shoots termed an inflorescence or, after the fruit is formed, an infructescence. (See FLOWER; FRUIT). Such inflorescences are wanting or ill developed among the Gymnosperms, while in the Angiosperms they are often well differentiated, constituting unities of a higher order. The modifications exhibited by the fertile shoots of such an inflorescence are due, partly to a difference in their mode of branching, partly to the reduction or the metamorphosis of their leaves. These changes are the result of an adaption to pollination, in the endeavor to aggregate and at the same time render the flowers more conspicuous by the reduction of the foliage-leaves. Sometimes the whole system of fertile shoots is converted into an attractive apparatus, as in the *Araceæ,* where the axis and the subtending leaf of the inflorescence have assumed the function, usually exercised by the perianth, of enticing insects. Viewed from a purely morphological standpoint, two types of inflorescences may be distinguished, the Botryose (racemose, monopodiale) and the Cymose.

INFLUENZA. The word is derived from the Italian *influenza di freddo,* influence, effect of cold. The other common name is grippe or grip, from the French *agripper,* to attack, or from *gripper,* to grip. The French name dates from 1712. Influenza is a febrile affection involving the respiratory tract oftenest, but attacking almost any set of tissues, especially the mucous membranes. It usually occurs as a pandemic, that is, an infection spreading to every people. It has been seen as a pandemic often since the early 16th century and there are accounts of it before. The epidemic of 412 B.C., mentioned by Hippocrates and Livy, is considered to have been influenza. The first American epidemic was in 1647, when some 6,000 deaths occurred in the Barbadoes and Saint Kitts. Cromwell is said to have died from it some 10 years later. There were four pandemic influenza periods in the last century — 1830–33; 1836–37; 1847–48; and the one recalled the best, that of 1889–90. This began in Turkestan in June 1889. By the end of the year it was as far west as the Pacific. It crossed the Pacific to rage in India the following spring and in a year and a half it had circled the globe. The disease probably always originates in the East at a time when crowded populations are suffering from want and therefore lack resistive vitality against the specific microbe which gains in virulence as the result of having such favorable material to multiply in. The affection usually attracts the attention of the medical world in some European country intimately in touch with the East. It rages with virulence and receives as an epithet the name of that country for a time. The epidemic at the end of the 19th century, first noted in Russia, was for some time called Russian influenza. The epidemic of 1918–19 was, for a similar reason, called Spanish influenza.

The duration of the disease in any locality is usually under two months. There is probably no disease which attacks so large a proportion of the inhabitants of infected territory. Often one-fourth, sometimes even more than one-third, of the population catch the disease. Unlike most other diseases, adults from 20 to 40 suffer most. Infants are almost immune; the old, particularly if they have gone through a previous epidemic, seem to be protected to a great extent. Some protection is undoubtedly afforded by a previous attack, though a few persons seem to be thus predisposed to subsequent attacks. The mortality of uncomplicated influenza is low. In the German army in 1889–90, out of some 60,000 cases the mortality was not more than one-tenth of 1 per cent. The deaths from pneumonia and other complications make the disease serious. Most of the deaths during an epidemic are due to pneumonia. The disease is much more fatal at the beginning of the epidemic in any locality and deaths may take place even in strong, young, healthy adults, within two or three days after the first symptoms are manifest. The index that the epidemic is about to wane is that the disease becomes much less severe in its symptoms and less fatal. It is usually not until after this that the number of patients attacked begins to reduce and then the mortality drops rapidly. The latest epidemic followed all these rules rather closely.

The cause of the disease is not known for certain. The so-called influenza bacillus, found by Pfeiffer (1892), is practically always present in the disease and is considered by a great many good authorities to be the cause, but the etiology is not definitely settled. Other microorganisms supposed to be concerned in the causation of special epidemics have been described, notably a filterable virus, that is, a microbic agent so small that it passes through the pores of a laboratory filter, but this has not been confirmed with any degree of certainty up to the present time. The presence of this agent was noted in many cases during the recent epidemic. The disease does not spread through the air but is a true contagion requiring for transmission contact, direct or indirect, with an individual suffering from the disease. The bacillus of Pfeiffer has been found in a very great many cases in large numbers in the secretions of the nose, throat and lungs, though the supposition that it must produce catarrhal symptoms, running from the eyes and nose, has not been confirmed in the present epidemic. It is found to exist luxuriantly in the back of the throat, growing in and between the cells and being distributed from here through the body to produce the respiratory or gastro-intestinal symptoms. The infection may readily occur therefore from the hands in eating, and one of the most important precautions against the disease is thorough cleansing of the hands before meals. The bacillus may be scattered around for considerable distances by coughing or sneezing, so that it is important to insist on the use of a handkerchief, or still better, of some waste cotton material or soft paper that can be burned, to be placed before the nose and mouth during sneezing and coughing.

The best protective against the disease is a state of vigorous health. The respiratory organs particularly should be kept in the best possible health and that is secured by plenty of outdoor air, especially in the sunlight. People who are run down in health should avoid coming in contact with patients affected by the disease, though apparently the presence of tuberculosis in the lungs, in spite of its consumptive effect, helps to protect against rather than predispose to the disease, for tuberculosis patients do not suffer much from influenza. The mouth and nose should be kept clean, but rough cleansing or the use of strong antiseptics will probably do more harm than good. The cells of the mucous membrane of the mouth and nose may be rendered less capable of resisting invasion. The use of chemical protectives and the carrying of camphor and other odoriferous materials with the thought that they protect against the disease is without confirmation in experience. The treatment of the disease is that of fevers in general but with an abundance of fresh air. During the epidemic of the '90's the coal-tar products, antipyrin, acetanilid and other similar materials were used in large quantities because they reduced the fever and made the patient more comfortable by their anodyne effects. They have a tendency to favor the destruction of red blood corpuscles and as the disease has a similar tendency, the combined result was often serious for the patient. They probably did much more harm than good. The pains in the bones at the beginning of influenza represent the effect of the disease on the blood forming marrow of the flat bones and the consequent blood deterioration predisposes to heart and other complications, hence the necessity for rest, once the fever declares itself, which should be continued until the extreme feeling of prostration often associated with the disease is relieved. The individual must be helped by general supporting treatment until the tissues are able to throw off the disease. Without complications the fever usually comes down on the fourth or fifth day, but the patient often has to stay in bed for nearly a week longer. When pneumonia occurs it is lobular, attacking the lobules and not the lobes of the lungs and ends by lysis, that is, by gradual absorption of the effusion, and not by crisis as in ordinary pneumonia. Supporting treatment is extremely important. The bowels must be kept regular so as not to interfere with movements of the diaphragm, and above all, the patient's mind must be set at rest as far as possible. Discouragement is a serious element for the prognosis and patients must not be told of the death of relatives or friends. Alcohol has been used with reported benefit, but the only good effect it may have is by lessening the dread of the affection which in some people's minds amounts to a serious pathological factor.

After previous epidemics of influenza, the disease has always become endemic, that is, sporadic cases of it have occurred years afterward, sometimes almost in epidemic form. This will almost surely happen at this time also, so that respiratory affections, especially in the changeable seasons of the year, will take on a special influenzal character. The particular strain of the bacillus whose evolution has been fostered by war conditions will gradually lose virulence, but continue with us for some time.

JAMES J. WALSH, M.D.

INFORMATION, a proceeding for some offense, usually against the government, differing from an indictment in not being found by a grand jury. It is usually brought by an authorized public official and is in use in the United States and England. The use of the information in the United States is restricted to misdemeanors in criminal cases, and it is allowed in certain civil cases, as to bring a person into court who has assumed the duties of a civil office to show by what authority he so acts, or to arraign a corporation for failing to observe the provision of its charter, etc. In England to-day information in criminal cases is brought by the Attorney-General or Solicitor-General, but not for treason, misprision of treason or felonies. However, it is rarely used there except for aggravated offenses, such as sedition, or crimes that are pernicious, as attempting to bribe public officials. In addition, informations are filed in the Court of Exchequer in revenue cases. In the United States also, in some jurisdictions, violations or attempted violations of the revenue laws are proceeded upon by information. The term is also applied to the written sworn statement made, as before a committing magistrate, prior to the issuance of a summons or complaint against a person charged with certain offenses.

INFORMER, a person who sues for a penalty against those who have infringed any law or penal statute. To encourage the apprehending of certain felons, guilty of offenses not so much criminal as bordering on criminality, many English statutes, from 1692 downward, granted rewards to such as should prosecute to conviction. The penalty in whole or in part inflicted in the case of a successful conviction and immunity from certain troublesome parish offices were the inducements held out to informers. In many cases this practice has been resorted to in modern statutes. But the institution of a Crown prosecutor in England and of prosecuting attorneys in the United States has nullified the importance of informers to a great extent. In the United States one who informs the government of the whereabouts of smuggled goods, counterfeit money, etc., is rewarded by a fee of 10 per cent of the net value of the confiscated goods. In criminal law (q.v.) an informer is said to turn state's evidence.

INFRALAPSARIANISM, in soteriology, the characteristic theological tenet and practice of those Calvinists and even also of some Roman Catholics, who maintain the dogma of absolute divine decrees of election and approbation and consider the decree of election as contemplating the apostasy as a past event, and the elect as being at the time of election in a fallen and guilty state. Infralapsarianism is really synonymous with sublapsarianism, and is opposed to supralapsarianism. Sublapsarianism conveys the general idea of having been «done after the time of the fall of man»; and this too is the meaning, considered etymologically, of infralapsarianism also. The Infralapsarians suppose that God in predestinating had respect to man, not merely as a fallen being, but specifically as either also redeemed through union with Christ, or as condemned through final impenitence. This, it need scarcely be said, amounts to an assertion that God decrees men to suffer His wrath on the ground of their foreseen guilt. This is the ultra-Calvinism of the Gomarist school. And it is consciously or unconsciously, implicitly or explicitly, presupposed — that an all-loving God somewhere in His Word appears as Creator of men simply with the sovereign purpose of then damning them eternally! It assumes likewise that believers are elected on the ground of foreseen faith and obedience, whereas the finally impenitent are predestinated to perdition by a damnatory decree on the grounds of their foreseen impenitency. This rigid Christianity refers the eternal election of men and their reprobation by God to his foreseeing, rather than his positively decreeing, that all men would fall in Adam, and thus would deserve reprobation; and thus the election of grace becomes conceived as simply a remedy for existing evil. Out of the entire mass of mankind thus fallen, God in his sovereign grace freely elects a certain number to life; and by virtue of the same electing act, He in an equal exercise of his sovereignty leaves others, non-elect, to the death which their sins deserve. Some, calling themselves Preteritionists, hold a modified — can it be said a less gloomy? — view on this subject. These reject the dogma that God has determined in the exercise of his authority to elect any, but to blessing. Yet they nevertheless contend for the decree of preterition, in virtue of which God has determined to pass by those who are not saved. Can it be necessary more than to allude to the gross fatalism inherent in

all these dogmas? Here the Bible takes on the aspect of a gloomy epic, terrible and grand as the elder 'Edda,' a book to plunge man into melancholy; the prophets thunder out doleful menaces; men burden their minds with the pitiless doctrines of Calvin. Fancy, if you can, the effects of such ideas on solitary and morose minds! An anthropomorphic superstition pervades them all. Admitting for a moment that God decrees anything at all (which, seriously, is to look upon him as Zeus, or even as a human legislator, making enactments) — might one not logically adopt the principle that He decrees in respect of what He does, but not in respect of what He does not do; and conclude that He decreed, by an absolute decree, to save the saved, but did not decree not to save the lost? And, obiter dicta, in all fatalism, whether (said to be) Christian, Mohammedan, Hellenic, Old Norse, Roman or Teutonic, whether Materialistic, Socialistic, Individualistic or Intellectualistic — and all are *variations* on a single theme — there is involved a fictitious idea both of causation and of necessity. Man's will is free. And it is no more logical — and this all determinists do, whether openly or tacitly — to presuppose that prevision creates the future, than to presuppose that memory creates the past.

INFRINGEMENT, a breach or violation of an agreement or right, especially the infraction of the copyright, patent rights or trademark of another. The usual method of procedure for the injured party is to secure an injunction restraining the infringement and to enter an action for the damages sustained. See COPYRIGHT; PATENTS, etc.

INFUNDIBULUM. See PITUITARY BODY.

INFUSION, in pharmacy, an aqueous solution of a medicinal substance obtained by treating with water, usually without the aid of boiling. The water may be either hot or cold, varying with the object to be obtained. According to the directions of the United States Pharmacopœia, infusions are generally prepared by pouring boiling water upon the drug and macerating in a tightly closed vessel until the liquid cools. The active principles are in this manner extracted more rapidly and, as a rule, in much larger portions than if the solution is colder. Heat is not advisable if the active principles are volatile. If an infusion is desired of a greater degree of concentration than that obtained by the process of maceration, it is frequently prepared by percolation, in which operation the drug is sliced or broken up into small fragments, packed in a percolator, and the water, either hot or cold, is passed through. Infusions are sometimes made with the aid of other liquids than water, but this is the exception rather than the rule. Infusions do not keep well, and therefore they should be made extemporaneously and in small quantities. In household medicine, infusions are very widely employed. These may be made at home or made by the pharmacist. It is essential to remember that if they are made in hot weather in large quantities they must be sterilized.

Infusion of saline solution into the blood-vessels is a very important procedure in medicine. It is employed largely in the treatment of shock and in severe hemorrhage, especially following operations or childbirth. The solution that is used is known as a normal salt-solution and consists of about one teaspoonful of common salt to a pint of water. This solution should be boiled carefully for one-half to three-quarters of an hour, the amount of evaporating water being made up as the boiling proceeds, and after being made it should be kept in large bottles provided with cotton plugs for stoppers. In severe cases of hemorrhage, infusion has often saved life, as it provides a body of fluid on which the heart and blood-vessels can act. The salt-solution is usually introduced into one of the large veins of the arm at a temperature of one to two degrees above that of the body temperature. See BLOOD; TRANSFUSION.

INFUSORIA, protozoa or organisms of the primary division of the animal kingdom, consisting of single cell or groups of cells, of the classes *Flagellata* and *Ciliata,* so-called from propagating and abounding in infusions of organic matter. While the term, first used in 1763, is now restricted to the ciliate protozoans, it often includes the flagellate protozoans as well. The latter are represented by the monads. These are exceedingly minute, round or pear-shaped animals, which move by one or two lash-like processes called flagella. They contain a nucleus and contractile vesicles. Some of them are fixed by a stalk, and are provided with a collar, as in *Codosiga,* out of which the flagellum projects. One of the simplest monads (*Heteromita*) is obtained by placing a cod's head in water at a temperature of about 70° F. In a few days the water will swarm with these monads. The young germs will live in boiling water, but perish at a temperature of from 212° to 268° F., while the adults are destroyed at 142° F.

In the ciliata infusoria the body is more or less flattened and covered with cilia (*Paramecium,* etc.). They have on the under side of the body a slightly defined mouth (or cytostome), which is permanently open, and the food is swept into it by the action of the cilia around it. The mouth leads into a funnel-shaped throat or cytopharynx, which ends in the protoplasm of the body. The food-particles swept into this throat and pressed into the protoplasm form a small enlargement which finally sinks farther in forming the "food vacuole," which, by the flow of the protoplasm, is carried about the body, while the digestible portions are absorbed and the waste matter is cast out at a fixed point,— a sort of vent (cytopyge). The fresh-water forms have contractile vesicles, and in certain species the animal possesses so-called stinging rods (trichocysts), which are very minute and are placed vertically to the surface of the cortex; by some students they are supposed to be tactile rather than stinging structures. What correspond to the muscular fibres of the higher animals cause the quick convulsive movements observed in these creatures. Two important organs are present in all ciliate infusoria, that is the nuclei. The larger nucleus (macronucleus) is an oval, rod-like or spiral body, which appears to control the processes of feeding and motion. The other nucleus (micronucleus) is much smaller and is concerned with reproduction. Reproduction occurs usually by self-division, and more rarely the infusorians contract into a ball and divide into spores, which grow to become adults. The periods of fission are at times interrupted by the process of conjugation, which only differs from sexual reproduction in the fact that two individual infusorians meet and fuse together and then separate, the result being a process of fertilization which leads to a complete new formation of the nucleus, and thus to a new organization of the animal.

The more specialized infusoria are *Stentor* and *Vorticella.* The former is large enough to be seen without a lens. It is purplish, and under the microscope shows itself to be a beautiful creature. It is trumpet-shaped, with a spiral tract of thicker cilia around the mouth-end. The most highly organized infusoria are the bell-animalcules (*carchesium,* etc.), which are compound bell-shaped forms, forming colonies with forked branched stalks. The nucleus is sausage-shaped, and near it is the micronucleus. They form a white mass like mold on the stems and leaves of aquatic plants. Some of the infusoria are parasitic in the digestive and circulatory organs of the higher animals. For a more detailed and illustrated account, consult, W. Saville-Kent's 'Manual of the infusoria, including a description of all known flagellate, ciliate and tentaculiferous protozoa, British and foreign, and an account of the organization and affinities of the sponges' (London 1880–82).

L., 'Study on the life history of hypotrichous infusoria' (Baltimore 1905).

INFUSORIAL EARTH, a term often but incorrectly applied to diatomaceous earth. See DIATOMS.

INGALLS, in'gălz, **James Monroe,** American soldier: b. Sutton, Vt., 25 Jan. 1837. He served in the Civil War, participating in the Atlanta campaign, and remained in the South during the Reconstruction period until 1871. In the following year he was graduated at the Artillery School, Fort Monroe, Va. In 1882 he founded the department of ballistics at the United States Artillery School, Fort Monroe, and was principal instructor there until the school suspended operations in April 1898, on the outbreak of war with Spain. He was retired from the army 25 Jan. 1901 and was advanced to the rank of colonel, retired, by act of 23 April 1904. He has written on professional topics for encyclopedias and in the *Journal of United States Artillery* and the volumes 'Exterior Ballistics' (1883; 1885; 1886); 'Ballistic Machines' (1885); 'Handbook of Problems in Exterior Ballistics' (1890; 1901); 'Interior Ballistics' (1894; 1911); 'Ballistic Tables' (1891; 1900); 'Ballistics for the Instruction of Artillery Gunners' (1893).

INGALLS, John James, American lawyer: b. Middleton, Mass., 29 Dec. 1833; d. Las Vegas, N. Mex., 16 Aug. 1900. He was graduated from Williams College in 1855, and was admited to the bar in 1857. In 1858 he moved to Kansas and established a law practice there, first in Sumner, and in 1860 in Atchison. In 1859 he was a delegate to the First Constitutional Convention. He was secretary of the territorial council in 1860, and of the State senate in 1861, and in 1862 was elected a member of the senate. During the Civil War he acted as judge-advocate of the Kansas militia (1863–65) and for three years edited the Atchison *Champion.* In 1873 he became a Republican member of the United States Senate, and was re-elected in 1879 and 1885. Charges that bribery had been practised in connection with his election in 1879 were made in and investigated by both the Kansas house of representatives and the United States Senate. They were found to be partially true, but Senator Ingalls himself was entirely exonerated and the claim to his seat was fully sustained. He was president pro tem. of the Senate from 1887–91. In 1891 he was again a candidate for senator, but was defeated by the Farmers' Alliance. During his service in the Senate he was known as one of its most eloquent members. From that time till his death he devoted himself chiefly to lecturing and writing. His writings were published by Conelley, W. E., ed., 'A Collection of the Writings of J. J. Ingalls' (Kansas City 1902). Consult Inman, H., 'J. J. Ingalls' (in 'Distinguished American Lawyers,' H. W. Scott, ed., p. 457, New York 1891); Kansas Bribery Investigation Committee, 'Report of the Special Committee of the Kansas House of Representatives, etc.' (Topeka 1879); Taft, G. S., 'Compilation of Senate Election Cases' (49th Congress, 1st Session, Senate Misc. Doc., No. 47, Washington 1885).

INGALLS, Melville Ezra, American railroad president: b. Harrison, Me., 6 Sept. 1842; d. 11 July 1914. He was educated at Bowdoin and at Harvard. He practised law successively at Gray, Me., and at Boston, Mass. In 1867 he was elected to the senate of Massachusetts. Becoming interested in railroads he was, in 1870, president of the Indianapolis, Cincinnati and Lafayette Railroad and in the following year was appointed its receiver. After effecting a thorough reorganization he added other roads which together are known as the "Big Four," the Cleveland, Cincinnati, Chicago and Saint Louis Railroad. He was chairman of the system until 1912 when he retired. He was also for many years executive head of the Chesapeake and Ohio Railway Company and in 1905 was chosen president of the National Civic Federation.

INGALLS, Rufus, American soldier: b. Denmark, Me., 23 Aug. 1820; d. New York city, 15 Jan. 1893. He was graduated from West Point in 1843, fought in the Mexican War and was brevetted first lieutenant for gallant and meritorious conduct. In 1854–55 he was a member of Steptoe's expedition to the Northwest. At the outbreak of the Civil War he defended Fort Pickens, Fla., then became quartermaster of the Army of the Potomac, and was present at many of the important engagements, was twice brevetted for gallant and

meritorious conduct, and at the close of the war had attained the rank of major-general. In 1867 he became successively quartermaster of the military division of the Atlantic, Pacific and the Missouri, quartermaster-general of the United States army, and brigadier-general in 1882 and was retired in 1883.

INGE, ĭnj, **William Ralph,** English clergyman and author: b. Crayke, Yorkshire, England, 6 June 1860. He was educated at Eton and at Kings College, Cambridge, where he won many honors. He was assistant master at Eton, 1884–88. At the same time, 1886–88, he was Fellow of Kings College. In 1889–1904 he became Fellow and tutor of Hertford College, Oxford. He was vicar of All Saints, Ennismere Gardens, London, 1905–07, Margaret professor of divinity, Cambridge 1907–11, and since 1911 dean of Saint Paul's, London. He was select preacher at Oxford 1893–95, 1903–05; at Cambridge in 1901, 1906 and 1910. In 1899 he delivered the Bampton Lectures, and in 1906 he delivered the Paddock Lectures in New York City. In 1915 he was lecturer at Sion College. In 1902 he was examining chaplain for the bishop of Lichfield. He is the author of several school books and is an authority on the subject of mysticism. His works include 'Society in Rome Under the Cæsars' (1886); 'Christian Mysticism' (1899); 'Faith and Knowledge' (1904); 'Selections from the German Mystics' (1904); 'Studies of English Mystics' (1906); 'Truth and Falsehood in Religion' (1906); 'Personal Idealism and Mysticism' (1907); 'Faith' (1909); 'Speculum Animæ' (1911); 'The Church and the Age' (1912); 'Authority and the Inner Light' (1913); 'Types of Christian Saintliness' (1915).

INGELOW, ĭn'jĕ-lō, **Jean,** English poet and novelist: b. Boston, Lincolnshire, 17 March 1820; d. Kensington, London, 20 July 1897. Her first published work appeared anonymously in 1850 under the title 'Rhyming Chronicle of Incidents and Feelings.' It was followed by 'Allerton and Dreux: or the War of Opinion' (2 vols., 1851), a story, and 'Tales of Orris' (1860); but not till the publication of 'Poems,' in 1863, did Miss Ingelow become famous. This volume won the enthusiastic praise of critics and the instant approval of the public, and by 1879 had passed through 23 editions. The most widely appreciated poems in it are 'The High Tide on the Coast of Lincolnshire'; 'Songs of Seven'; 'Divided'; and 'Supper at the Mill.' Later volumes were 'Studies for Stories' (1864); 'Stories told to a Child' (1865); 'Poor Mat' (1866); 'A Sister's Bye-Hours' (1868); 'Mopsa the Fairy' (1869); 'Off the Skelligs' (4 vols., 1872), her first long story; 'The Little Wonder Horn' (1872), a new series of stories told to a child; 'Fated to be Free' (3 vols., 1881); 'Sarah de Berenger' (3 vols., 1879); 'Don John' (3 vols., 1881); and 'John Jerome' (1886). A second volume of verse, 'A Story of Doom and Other Poems,' appeared in 1867 and a third volume, 'Monitions of the Unseen' in 1885. Collections of her poems were published as 'The Poetical Works of Jean Ingelow' (New York 1894; London 1898). Her works have been even more popular in America than in her native country. She was at her best as a writer of children's stories, even though her popularity during her life was based chiefly on her poetry. The latter contains some few very excellent pieces, but the bulk of it has not stood the test of time. In her own days, however, she was greatly admired for her songs, and many of her poems, indeed, have considerable lyrical merit. Consult Anon., 'Some Recollections of Jean Ingelow and her Early Friends' (London 1901); Stuart, G. B., 'Personal Recollections of Jean Ingelow' (in *Lippincott's Monthly Magazine,* Vol. LXXVII, p. 306, Philadelphia 1906).

INGEMANN, ĭng'ĕ-man, **Bernhard Severin,** Danish poet and novelist: b. Torkildstrup, on the island of Falster, 28 May 1789; d. Sorö, 24 Feb. 1862. He was educated at the University of Copenhagen, and it was while a student there that he published his first 'Poems' (1811–12), of a dreamy, melancholy nature, showing the influence of German romanticism, and displaying the unhealthy state of his body and mind. In 1814 he published a long allegorical poem, 'The Black Knights,' which showed a marked advance. The next six works which he produced were plays, the tragedy 'Blanca,' brought out in 1815, being the most popular and successful, though 'The Miraculous Child Reinald' (1816) was undoubtedly the best. 'The Subterranean Ones, a Story of Bornholm,' his first prose work, was written in 1817, and the following year he started on a tour of the Continent, returning in 1819. On his return he wrote his 'Stories and Miraculous Tales,' which was published in 1819, followed in 1820 by two volumes of poems, 'The Travel Lyre,' and in 1821 by a comedy, 'Magnetism in a Barber's Shop,' which, however, was unsuccessful, and thereafter he confined himself to prose work. In 1822 he accepted the chair of Danish language and literature at the Academy of Sorö, and then began his voluminous writings on historical subjects, his novels probably being inspired and copied from the Waverly novels, by Scott. The subjects and characters were taken from Danish history, and, while they were to a great extent inaccurate, were possessed of such strong nationality that they became of great interest. Among these historical romances were 'Valdemar the Victorious' (1826); 'Erik Menved's Childhood' (1828); 'King Erik and the Outlaws' (1833); 'Prince Otto of Denmark and His Time' (1835); 'Queen Margaret' (1836); 'Holger Danske' (1837). From 1837–39 he wrote a collection of 'Evening and Morning Songs,' which became very popular on account of their great beauty of religious expression. From this time until his death his writings were mainly religious and the last of his works, 'The Apple of Gold,' was published in 1856. A number of his works have been translated into English and many of them into German. His collected works in 41 volumes were published in Copenhagen (1843–65). He left an autobiography which was edited by Galskjöt (1862). His correspondence was published in 1879, edited by V. Heise, and his letters to Grundtvig were edited by S. Grundtvig (1882). Consult Brandes, G., 'Essays' (Copenhagen 1889); Nörregaard, J., 'B. S. Ingemanns Digterstilling og Digterværd' (Copenhagen 1886); Petersen, R., 'Mindeskrift over B. S. Ingemann' (Copenhagen 1889): Schwanenflügel, H., 'Ingemanns Liv og Digtning' (Copenhagen 1886).

INGENHOUSZ, ĭng'ĕn-hous', **Jan,** Dutch physician and scientist: b. Breda, Holland, 8 Dec. 1730; d. Bowood, the seat of the Marquis of Lansdowne, England, 7 Sept. 1799. He studied medicine at Louvain, Leyden, Paris and Edinburgh, and after practising in his own country for several years removed to London in 1764 or 1765. In 1769 he was appointed aulic councillor and body physician to the Austrian Empress, Marie Theresa, and to Joseph II, introducing vaccination against smallpox in Vienna. After serving for nine years in that capacity he returned to London, where he began his scientific researches, later becoming a fellow of the Royal Society, and publishing in its 'Philosophical Transactions' several treatises and essays. From 1780–89 he again resided in Vienna, devoting himself chiefly to experiments in chemistry, physics and botany. From 1789–99 he lived in England. His works include 'Experiments on Vegetables, Discovering Their Great Power of Purifying the Common Air in Sunshine, but Injuring it in the Shade, or at Night' (London 1779; Leipzig 1780; Paris 1787–89); 'Respiration of Plants' (Vienna 1786); 'Miscellanea Physico-Medica' (Scherer, J. A., ed., Vienna 1795); 'Essay in the Food of Plants and the Renovation of Soils' (London 1796). Collections of his scientific papers were published in German (Vienna 1785) and in French (2 vols., Paris 1785–89). Dr. Ingenhousz is credited with being the discoverer of carbonic acid, assimilation of plants, and he also invented the plate electrical machine. Consult Weisner, J., 'Jan Ingen-Housz' (Vienna 1905).

INGERSOLL, ing'gĕr-sōl, **Charles Jared,** American statesman, lawyer and author; son of Jared Ingersoll (q.v.): b. Philadelphia, 3 Oct. 1782; d. there, 14 May 1862. After finishing his collegiate course he studied law, was admitted to practice, traveled in Europe and became attached to the American embassy to France. In 1812 he was elected to Congress, taking his seat in May 1813. In 1815 he was appointed United States district attorney for Pennsylvania, an office which he held until 1829. Shortly after he was elected to the legislature of Pennsylvania. He was a member of Congress 1841–47 as representative of one of the districts of which the county of Philadelphia was then composed. He was the author of the poem 'Chiomara' (1800), of the tragedy 'Edwy and Elgwia' produced in Philadelphia (1808), of 'Julian' (1831); and of 'Inchiquin — the Jesuit's Letters on American Literature and Politics' (1810); 'Historical Sketch of the Second War between the United States and Great Britain' (4 vols., 1845–52), etc. Consult Meigs, W. W., 'Charles Jared Ingersoll' (Philadelphia 1898).

INGERSOLL, Ernest, American naturalist: b. Monroe, Mich., 13 March 1852. He studied at Oberlin College and in the Lawrence Scientific School and Museum of Comparative Zoology of Harvard University, where he was a pupil of Agassiz, and in 1874 and 1877 was connected as naturalist with the Hayden survey. He was also an expert on the United States Fish Commission, and later became known as a popular writer and lecturer on scientific subjects. In 1901 he was lecturer in zoology at the University of Chicago. Among his works are 'Nests and Eggs of North American Birds' (1880–81); 'Oyster Industries of the United States' (1881); 'Knocking 'Round the Rockies' (1883); 'Country Cousins' (1884); 'The Crest of the Continent' (1884); 'Down East Latch-Strings' (1887); 'Wild Neighbors' (1897); 'The Book of the Ocean' (1898); 'Nature's Calendar' (1900); 'Wild Life of Orchard and Field' (1902); 'The Life . . . of Mammals' (1906); and several popular juvenile tales, notably 'The Ice Queen.' He is editor of the 'Farmer's Practical Library,' secretary of the Authors Club (New York), and an officer of the National Association of Audubon Societies.

INGERSOLL, Jared, American politician: b. Milford, Conn., 1722: d. 1781. Upon the passage of the Stamp Act he was appointed, in 1765, a stamp agent in Connecticut and accepted the post by the advice of Franklin. This subjected him to the personal abuse and insults from which all colonial stamp agents suffered, and finally he was forced to resign; later, in 1770, becoming an admiralty judge. He was the author of a pamphlet called 'The Stamp Act' (1776).

INGERSOLL, Jared, American lawyer: b. Connecticut 1750; d. Philadelphia, 21 Oct. 1822. Having been graduated at Yale College in 1766, he went to London, was entered of the Middle Temple and passed five years in the study of law. The American Revolution breaking out while he was still in London, he espoused the cause of the colonies, although the son of a Loyalist. He went from London to Paris, where he remained for 18 months, making the acquaintance of Franklin. Returning home, he took up his residence in Philadelphia, where he won almost immediately a prominent position as a lawyer. In 1787 he was chosen one of the representatives of Pennsylvania in the convention which framed the United States Constitution. Twice attorney-general of the State, he was United States district attorney for Pennsylvania, presiding judge of Philadelphia County District Court and in 1812 the Federal candidate for Vice-President of the United States.

INGERSOLL, Leonard Rose, American educator: b. New York, 1 June 1880. He was graduated at Colorado College in 1902 and received the degree of D.Ph. at the University of Wisconsin in 1905. In 1905–08 he was instructor, in 1908–10 assistant professor, and since 1910 associate professor of physics at the University of Wisconsin. He is a Fellow of the American Association for the Advancement of Science and member of the American Physical Society. He was a member of the Smithsonian expedition to Mount Wilson, Cal., for solar investigations in 1905, 1906 and 1909. With O. J. Zobel he published 'An Introduction to the Mathematical Theory of Heat Conduction' (1913). He has contributed many articles to scientific journals, chiefly on subjects connected with the electro-magnetic theory of light.

INGERSOLL, Robert Green, American lawyer, lecturer and author: b. Dresden, N. Y., 11 Aug. 1833; d. Dobb's Ferry, N. Y., 21 July 1899. He received a common school education

in various towns in Ohio and Illinois where his father, a minister, held charges and was admitted to the bar at Mount Vernon, Ill., in 1854. He soon became prominent in the courts and in Democratic politics. In the Civil War he recruited the 11th Illinois Cavalry and entered the army as its colonel. He was in the battle of Shiloh and saw considerable fighting in Tennessee. On 18 Dec. 1862, while trying with a force of 600 men to intercept a Confederate raiding party, he was captured by a force of 10,000 men but was soon paroled and given command of a camp in Saint Louis. He soon afterward resigned. After the war he became a Republican, and was made attorney-general of Illinois in 1867. He was a delegate to the Republican National Convention in 1876 and placed in nomination for President James G. Blaine, whom he termed "the plumed knight." His nominating speech gave him national reputation as an orator, and he afterwards lectured frequently, always before immense crowds. He was an agnostic and in his lectures attacked the Bible and the beliefs of the Christian religion. He was prominent in politics for several years, and had he not given such frequent expression to his agnostic views he would doubtless have been honored with high offices, though, to judge from his refusal of two or three diplomatic posts, he was far from eager for office. He took up his permanent residence in New York city in 1882 and practised law there till his death, being one of the most successful trial lawyers of his times. His lectures on theological subjects formed for many years the basis of extensive and frequently violent discussion and attacks. His most famous lectures include 'Some Mistakes of Moses'; 'The Family'; 'The Liberty of Man, Woman and Child'; 'The Gods'; and 'Ghosts.' His publications include 'Lectures Complete' (1886); 'Prose, Poems and Selections' (1888); 'Famous Speeches' (1906); and 'Political Speeches' (1914). A complete collection of his works was published in 12 volumes (New York 1912). Consult Brann, H. A., 'The Age of Unreason' (New York 1881); Curtiss, S. I., 'Ingersoll and Moses' (Chicago 1880); Dement, R. S., 'Ingersoll, Beecher and Dogma' (Chicago 1878); Duganne, A. J. H., 'Injuresoul; a Satire for Science' (New York 1884); Goldthwaite, V., 'The Philosophy of Ingersoll' (San Francisco 1906); Hubbard, E., 'Ingersoll' (in 'Little Journeys to the Homes of Eminent Orators,' (Vol. XIII, p. 23, East Aurora 1903); Kittredge, H. E., 'Ingersoll; a Biographical Appreciation' (New York 1911); Lambert, L. A., 'Notes on Ingersoll' (Buffalo 1883); McClure, J. B., ed., 'Mistakes of Ingersoll, etc.' (Chicago 1879); United States War Department, 'The War of the Rebellion. (Official Records' (Series I, Vol. XVII, Washington 1886–87).

INGERSOLL, Royal Rodney, American naval officer: b. Niles, Mich., 4 Dec. 1847. In 1868 he was graduated at the United States Naval Academy. He was promoted through the various grades, attaining that of rear-admiral in 1908, and retired the following year. He has served as naval officer in all parts of the world. During the war with Spain he commanded the *Supply* and in 1905 was in command of the *Maryland*. He was member of the General Board of the Navy at the time of his retirement. On 7 July 1917 he was again placed on duty in the Bureau of Ordnance. He has published 'Text-Book of Ordnance and Gunnery' (1887); 'Exterior Ballistics' (1891); 'Elastic Strength of Guns' (1891).

INGERSOLL, Canada, town in Oxford County, Ontario, on the Thames River and the Grand Trunk Railway, 19 miles northeast of London. It is the marketing centre for a rich grain and fruit-producing section, and has an important trade in lumber, grain, cheese and general country produce. It has manufactures of iron products, machinery, agricultural implements, woolen goods, woodenware, lumber and creamery products; banks, and weekly newspapers. Pop. 4,763.

INGHAM, ĭng'ăm, **Benjamin,** English evangelistic leader: b. Ossett, Yorkshire, 11 June 1712; d. Aberford, 1772. He received his education at Batley School and at Queen's College, Oxford, where he graduated B.A. in 1734. In 1735 he was ordained, and, becoming associated with John and Charles Wesley, went with them to Georgia, remaining two years. In 1738 he went with John Wesley on a visit to the Moravians in Germany and became so strongly attached to their doctrines that he broke with the Wesleys and founded in Yorkshire several congregations of what were known as "Moravian Methodists," but more commonly as "Inghamites." He endeavored to unite in this organization the chief doctrines of the Moravians and Methodists, and so successful was he as bishop or general overseer that in a few years there were 84 of these congregations in England. He moved to Aberford about the time of his marriage with a daughter of the Earl of Huntingdon in 1741 and succeeded in converting the whole surrounding neighborhood to his faith. In 1760, however, the greater part of his followers deserted him after he adopted many of the mystical views of Robert Sandeman (q.v.). Only about 13 of the Inghamite churches followed him into the Sandemanian sect. The rest were absorbed by other sects, especially by the Methodists. He wrote 'A Discourse on the Faith and Hope of the Gospel' (Leeds 1763). Consult Tyerman, L., 'The Oxford Methodists' (London 1873).

INGHAM, Charles Cromwell, American painter: b. Dublin, Ireland, 1796; d. New York, 10 Dec. 1863. He was a pupil of William Cunning at the Dublin Academy, came to New York in 1817, was there a founder of the National Academy of Design (1826), and its vice-president in 1845–50. He painted many portraits and miniatures of beautiful women and children, as well as of prominent men; amongst the latter are to be mentioned portraits of De Witt Clinton and Lafayette. His works include 'Day Dream'; 'The White Plume'; 'The Flower Girl'; 'The Death of Cleopatra.'

INGLE, Richard, English sea captain of the 17th century. When the civil war arose in England Ingle was engaged in the tobacco trade in Maryland. He espoused the cause of the Parliament against Charles I and in 1645 expelled Governor Calvert from Maryland. The latter, however, gathered forces and again took possession of the province late in 1646. During the 20 months of his rule Ingle committed many outrages and plundered several of the inhabitants. Charges were made against him in England which he defended on the ground that he acted from religious motives and plundered only "Papists." When the proprietary government was restored Ingle was not included in the general amnesty granted to other rebels. On 14 Nov. 1653 he petitioned for a share of prize money and thereafter disappears from history. Consult 'Captain Richard Ingle, the Maryland Private and Rebel, 1642–53' (Baltimore 1884).

INGLEBY, ĭn'g'l-bĭ, **Clement Mansfield,** English author and Shakespearean critic: b. Edgbaston, near Birmingham, 29 Oct. 1823; d. Ilford, Essex, 26 Sept. 1886. After graduating from Trinity College, Cambridge, he entered into partnership with his father, but in 1859 gave up his law practice and moved to Ilford, where he began writing for the magazines on scientific and metaphysical subjects. His best-known works are his Shakespearean studies, among which are 'The Shakespere Fabrications' (1859); 'Shakespere Controversy' (1861); 'Shakespere's Centurie of Prayse, etc.' (1874); 'The Still Lion' (1874; new edition 1875, entitled 'Shakespere's Hermeneutics'); 'Shakespere: the Man and the Book' (1877–78). He also wrote 'Outlines of Theoretical Logic' (1856); 'An Introduction to Metaphysics' (1864–69), etc.

INGLEFIELD, Sir **Edward Augustus,** English admiral and explorer: b. Cheltenham, 27 March 1820; d. 5 Sept. 1894. He was educated at the Royal Naval College, Portsmouth; went to sea at 14, and participated in the naval operations on the coast of Syria in 1840. He became commander in 1845. He commanded the yacht *Isabel* in 1852 on a cruise to Smith Sound in search of Franklin. He published a narrative of this cruise, 'A Summer Search for Sir John Franklin' (1853). As commander of the *Phœnix* he afterward made three voyages to the Arctic; in 1854 he rescued part of the Belcher expedition and later in the same year made a last futile attempt to find Sir John Franklin. He took part at the siege of Sebastopol during the War of the Crimea. In 1877 he was knighted and two years later was made admiral. He invented the anchor known by his name and a hydraulic steering-gear. He was also a competent marine artist.

INGLIS, Ing'lz, Charles, American Anglican bishop: b. according to some authorities New York, according to others Ireland 1734; d. Halifax, Nova Scotia, 1816. After teaching school for a few years near Lancaster, Pa., he was ordained in England. He was at first assigned to a missionary post at Dover, Del., and in 1765 became assistant minister at Trinity Church, New York. About 1770 he became one of the governors of King's College, now Columbia University. A stout Loyalist, he refused to omit from the service the prayer for the king and royal family, and upon the occupation of New York by Washington retired for a time to Long Island. In 1770 he received an honorary M.A. degree, and in 1778 that of doctor of divinity, both from Oxford University. In 1777 he was chosen to the rectorship of Trinity, and in 1783, at the evacuation of New York by the British, went to Halifax in the emigration of the United Empire Loyalists. He was consecrated in 1787 bishop of Nova Scotia (with jurisdiction over the other North American provinces), and was the first colonial bishop of the Church of England. In 1809 he became a member of the Council of Nova Scotia. He published sermons and pamphlets. Consult Dix, M., 'A History of the Parish of Trinity Church in the City of New York' (4 vols., New York 1898–1906); Eaton, A. W. H., 'Bishop Charles Inglis and his Descendants' (in *Acadiensis,* Vol. VIII, No. 3, p. 183, Saint John 1908); O'Callaghan, E. B., ed., 'Documentary History of New York' (4 vols., Albany 1850–51); Perry, W. S., 'History of the American Episcopal Church' (2 vols., Boston 1885); Sabine, L., 'Loyalists of the American Revolution' (2 vols., Boston 1864); White, H. V., 'Charles Inglis, our First Colonial Bishop' (Dublin 1899).

INGLIS, John, Canadian bishop: b. New York 1777; d. London, England, 1850. He was a son of Bishop Charles Inglis (q.v.), graduated at King's College, Windsor, Nova Scotia, and was consecrated third bishop (Anglican) of Nova Scotia, 25 March 1825. He was a benefactor of King's College and viewed with disfavor the Anglican "test" imposed as a condition of entrance to that institution.

INGOLD, Augustin Marie Pierre, French clergyman and author: b. Cernay, Haute Alsace, 21 April 1852. He was educated at Colmar, Alsace, and at Saint Sulpice and the Sorbonne, Paris. In 1873 he joined the French Oratorians and three years later was ordained to the priesthood. He was successively librarian, archivist and professor of history and exegesis in the Paris scholasticate. Since 1899 he has been editor of the *Revue d'Alsace.* In 1914 he was made chaplain to the 30th Army Division. He has published about 200 works on Jansenism, Alsatian history and the history of the Oratorians. He collaborated in Vacant's, 'Dictionnaire de Théologie Catholique'; Vigouroux's 'Dictionnaire de la Bible'; Bandrillart's 'Dictionnaire d'histoire et de géographie ecclésiastiques'; and Cabral's 'Dictionnaire d'archéologie chrétienne et de liturgie.' He contributed to 'The Catholic Encyclopedia' and with Duchesne founded the *Bulletin Critique.*

INGOLDSBY LEGENDS, The, or MIRTH AND MARVELS (1837–40), by the Rev. Richard Harris Barham ("Thomas Ingoldsby"), a collection of tales, mostly versified and nearly all laughable, sets the standard for its kind. Other English humorous narrative verse may equal or surpass it in one quality or another — Thackeray's 'Ballads' in the delightful employment of vulgarisms; 'John Gilpin' and the 'Elegy on a Mad Dog' in simplicity; the 'Ballads of Bon Gaultier' in thinly veiled satire; 'Hudibras,' 'The Fable for Critics,' and much of Browning's serious verse in *tours de force* of whimsical rhyming; the 'Bab Ballads' in *bouffe* irresponsibility of theme and in sureness of rhythm; Thomas Hood's poetical tales in the mingling of grim pathos with humor; but none other combines these qualities so uniformly and in so large a body of verse. Ingoldsby has other merits of its own. Its verve is unfailing. Its literary sources are extraordinarily various, ranging from saints' legends, mediæval chronicles and Kentish local traditions, down to La Fontaine's 'Contes,' Goethe's 'Zauberlehrling,' and De la Motte Fouqué's 'Undine'; so that it offers the richest antiquarian farrago of witchcraft,

ghosts, magic, and demonology, with legal, genealogical, heraldic, ecclesiastical, and gastronomic history and anachronisms. Its careful technique in the details of narrative and description is in the tradition of Sterne; and its rollicking masculine fun is the peculiarly English fun of a by-gone day of roast-beef, puddings, and ale, a hierarchical social order, and a gentlemanly acquaintance with the classics. Its defects are the often flippant handling of themes essentially serious; the rarity of its genuine wit or humor—their place being generally occupied by fun and volubility; its employment of digression beyond the point where digression ceases to amuse and begins to bore; and its outworn insularity and prejudices. These penalties it pays for smacking so racily of its time and its land; Ingoldsby takes the gauge of early Victorian England relaxing over the nuts and wine; yet, all deductions made, does it so excellently well as to make itself the permanent model of its *genre*. Various editions are illustrated by Cruikshank, and by Leech and Tenniel. Early issues are now in request. Consult 'The Life and Letters of the Rev. Richard Harris Barham,' by his son, R. H. D. Barham (London 1870).

SAMUEL LEE WOLFF.

INGOLSTADT, Bavaria, town situated at the confluence of the Danube and the Schutter, 52 miles north of Munich. It contains an ancient ducal palace, now used as an arsenal, old university buildings, theatre, a Gothic Frauenkirche, a Franciscan convent and nunnery, ammunition works, a school of military engineering, gun powder works, cloth factories and breweries. It was a royal villa in the 9th century and received its charter as a town before 1255. In 1539 it was fortified. It suffered severely in the wars incident to the Reformation; was ceded to Austria in 1743 and in 1800 was taken by the French and its fortifications were dismantled. Since 1870 it has ranked as a fortress of the first-class and improved defensive works have since been erected. Pop. 23,745. Consult Gerstner 'Geschichte der Stadt Ingolstadt' (Munich 1853).

INGOT, a small bar of metal formed by casting it in molds. The term is chiefly applied to the bars of gold and silver intended for coining, although both iron and steel are molded into ingots.

INGRAHAM, ĭng'gra-am, **Duncan Nathaniel,** American naval officer: b. Charleston, S. C., 6 Dec. 1802; d. there, 16 Oct 1891. He entered the navy as midshipman in 1812, served during the War of 1812 and in the Mexican War before Vera Cruz and Tampico, and became a captain in 1855. While in command of the sloop-of-war *Saint Louis* he arrived at Smyrna 22 June 1853, and under instructions from the American Minister at Constantinople, took action in the case of the illegal arrest by order of the Austrian counsel, of Martin Koszta, an American citizen of Hungarian birth, which assumed considerable international importance. (See KOSZTA AFFAIR). After his return he acted for more than four years as chief of the bureau of ordnance and hydrography of the navy department. In 1860 he resigned from the United States Navy, entered the Confederate service and became a commodore, serving as chief of ordnance at Richmond, Va., and as naval commander at Charleston, S. C.

INGRAM, ĭn'grăm, **Arthur Foley Winnington,** Anglican bishop: b. 26 Jan. 1858, Worcestershire, England. He was educated at Marlborough College and Keble College, Oxford. He was a private tutor 1881–84; the next year he served as curate of Shrewsbury; 1885–89 he was private chaplain to the bishop of Litchfield; in 1889 he was chaplain to the archbishop of York and to the bishop of Saint Albans, at the same time he was head of Oxford House, Bethnal Green; rector of Bethnal Green 1895; rural dean of Spitalfields, 1896; canon of Saint Paul's, London, 1897–1901 and bishop of Stepney for the same period. Since 1901 he has been dean of the Chapels Royal and bishop of London. He has a wide reputation as a preacher. He is author of 'Work in Great Cities' (1895; 5th ed. 1909); 'The Men who Crucify Christ' (1896); 'Christ and His Friends' (1897); 'Banners of the Christian Faith' (1899); 'The Gospel in Action' (1906); 'Early English Colonies' (1908); 'Joy in God' (1910); 'Secrets of Strength' (1911); 'Attractiveness of Goodness' (1913); 'Eyes of Flame' (1915); 'Church in Time of War' (1916); 'Day of God' (1916); 'Gospel of the Miraculous' (1916); 'Under the Dome' (1916); 'Call of the Father' (1917); 'Potter and the Clay' (1917).

INGRAM, John Kells, English educator and author: b. County Donegal, Ireland, 7 July 1823; d. Dublin, 1 May 1907. He was educated at Trinity College, Dublin, and was appointed professor of oratory and English literature there in 1852, Regius professor of Greek in 1866, and librarian in 1879. At one time he was vice-provost of the college, and also held the presidency of the Royal Irish Academy. His 'History of Political Economy,' originally printed in the 9th edition of the 'Encyclopædia Britannica,' was separately published in 1888 and widely translated. He further wrote 'A History of Slavery and Serfdom' (1895); 'Sonnets and other Poems' (1900); 'Human Nature and Morals according to Auguste Comte' (1901), etc.

INGRASSIA, Giovanni Filippo, Sicilian physician: b. Palermo, 1510; d. there, 6 Nov. 1580. He studied at the University of Padua, where he received the degree of doctor in medicine in 1537. He taught with great success in Naples. He made several important anatomical discoveries. In 1563 he was named first doctor of Sicily by Philip II of Spain, and during the pestilence which devastated Palermo in 1575 he acquired the lasting esteem of its citizens by his work in suppressing the plague. He was granted a pension of 3,000 gold crowns. His more important works are 'Jatropologia, liber quo multa adversus barbaros medicos disputantur' (1558); 'De tumoribus præter naturam' (1553); 'Ragionamento sopra l'infermità epidemica del 1558' (1560); 'Methodus curandi pestiferum contagium' (1583); 'In Galenum librum de ossibus doctissima et expertissima Commentaria' (1603). Consult Eloy 'Dictionnaire historique de la Médicine.'

INGRES, Jean Dominique Auguste, zhŏn dō-mē-nēk ō-güst ăng-r, French historical

painter: b. Montauban, 29 Aug. 1780; d. Paris, 14 Jan. 1867. Placed in the school of David he made such rapid progress that in 1800 he gained the second, and in 1801 the first prize of the Academy of Fine Arts. In 1806 he departed for Italy, where he passed nearly 20 years first at Rome and then at Florence, abandoning, under the influence of a close study of Raphael and the old masters, the dry, classic style acquired from David. After his return to Paris he opened, about 1824, a studio where he taught. From 1834–41 he was director of the French Academy at Rome. In 1845 he was made a commander and in 1855 a grand officer of the Legion of Honor. In spite of these honors, he was at times excessively attacked on account of his artistic principles. His works are numerous, and comprise generally serious historical and classical subjects; in the great exhibition of 1855 at Paris an entire salon was appropriated to them and he was awarded a gold medal. Many are in Louvre, on the ceiling of one of the apartments of which is painted his 'Apotheosis of Homer.' He painted the portraits of many distinguished personages, including that of Napoleon I. The art of Ingres is adjudged to hold a middle place between the classic and the romantic schools. His weakest point was his coloring, his strongest his drawing. Amongst his best known works are 'Œdipus and the Sphinx'; 'Christ Delivering the Keys to Saint Peter'; 'The Sleep of Ossian'; 'The Triumph of Romulus'; 'The Vow of Louis XIII'; 'Francesca da Rimini'; 'Joan of Arc at the Coronation of Charles VII'; Portraits of Cherubini, Charles X, himself, etc. Consult Amaury-Duval, E. E. P., 'L'Atelier d'Ingres' (Paris 1878); Blanc, C., 'Ingres. Sa Vie et ses Ouvrages' (Paris 1870); Boyer d'Agen, R., 'Ingres d'après une Correspondance inédite' (Paris 1880); Chesneau, E., 'La Peinture Française au 19e Siècle, etc.' (Paris 1862); Cortissoz, R., 'Art and Common Sense' (New York 1913); Delaborde, H., 'Ingres, etc.' (Paris 1870); La Forge, A. de, 'La Peinture Contemporaine en France' (Paris 1856); Lapauze, H., 'Ingres, Chef d'École, 1824–34' (in *Nouveau Revue,* Ser. III, Vol. XX, p. 453, Vol. XXI, p. 19, Paris 1911); id., 'Ingres dans l'Atelier de David, etc., 1797–1806' (in *Grande Revue,* Vol. LXVI, pp. 72, 304, 749, Paris 1911); Merson, O., 'Ingres' (Paris 1867); Mirecourt, E. de, 'Ingres' (Paris 1856); Mommeja, J., 'Collection Ingres au Musée de Montauban' (Paris 1905); Moore, G., 'Modern Painting' (London 1893); Saunier, C., 'Exposition Ingres' (in *Les Arts,* Paris, July 1911); Silvestre, T., 'Les Artistes Français' (Paris 1878); Wyzewa, T. de, ed., 'L'Œuvre Peint de J. D. Ingres' (Paris 1907).

INHALATION, in medicine, a mode of applying remedies directly to the respiratory tract. Either steam alone, steam charged with drug-vapors, or drugs finely subdivided in sprays, are breathed into the air-passages as deeply as possible. This method of medication is useful only in relieving inflammations of the upper air-passages and possibly the trachea and larger bronchi. The air in the smaller bronchi is not changed by breathing, but by the diffusion of gases, so that substances in aërial suspension are deposited on the surface before reaching the smaller divisions of the bronchial tubes. Steam does not penetrate far, but is cooled, and deposits moisture as far as the trachea. The old-fashioned croup-kettle and many devices for carrying out the same idea are used for the first stages of laryngitis. Many substances, such as tincture of benzoin, etc., are added to the boiling water, but render it no more efficacious. Instead of conducting the steam directly to the mouth and nose by a funnel or tube, it may be well to place the patient in a simply enclosed tent, formed of bedclothes, and to allow the steam to charge the confined air. This method is particularly advisable for infants and older children.

INHAMBANE, e'nyam-ba'na, Portuguese East Africa, a station on the coast just south of the tropic of Capricorn. It has very many European buildings, churches, etc., and dates from the 16th century. It has a trade in ivory, copal, wax, nuts, rubber and other products of the colony. Pop. 4,000, a motley collection of Arabs, Banyans, half-castes and negroes, with about 150 Europeans.

INHERITANCE, *in law,* a perpetual or continuing right to an estate invested in a person and his heirs. There are nine "canons of inheritance"; three may be quoted: (1) That inheritance shall, in the first place, descend to the issue of the last purchaser in *infinitum;* (2) that the male issue shall be admitted before the female; (3) that where two or more of the male sex are in equal degree of consanguinity to the purchaser, the eldest only shall inherit, but the females of the same degree all together.

INHERITANCE TAX, an assessment laid upon those made heirs of property, either by distribution or descent. Sometimes this assessment is confined to collateral heirs, when it is called collateral inheritance tax. The raising of public funds in this way has been sanctioned by legislation from the beginning of Roman law, and in England and other countries is a large and steady source of revenue, although such taxes have been stigmatized by certain economists as "death duties." During the Civil War taxes of this kind were made part of the internal revenue system of the United States, but abolished soon after the struggle ended. The rate and method of assessment vary in different countries, and in different States of the Union. The English inheritance tax ranges from a 1 to a 10 per cent assessment, in accordance with the amount of the inheritance and the degree of relationship of heirs. In the United States lineal, collateral and succession inheritance taxes have been instituted in several States, as a source of domestic revenue. In Connecticut the assessment on inherited property is graded from 1 to 8 per cent, according to degree of relationship and valuation. In California, there is $10,000 to $24,000 exemption to near relatives, and then a graded tax from 1 to 15 per cent; distant relatives, $2,000 exemption and 3 to 25 per cent tax. In Delaware the assessment ranges 1 to 5 per cent, according to the amount of property left, and the degree of relationship. In Illinois, 1 per cent on values over $20,000 to lineal descendants; 2 per cent above $100,000, and 2 per cent to 5 per cent on all amounts to collateral relations. In New York, near relatives exempt to $5,000; 1 to 4 per cent on

larger bequests; non-relatives exempt to $1,000, above that graded from 5 to 8 per cent. In Ohio and Virginia, near relatives exempt, others 5 per cent on all values over $500. Nearly similar laws exist in Maryland, Missouri, New Hampshire, Pennsylvania, Vermont, Virginia and Delaware. In Alabama, District of Columbia, Georgia, Mississippi, New Mexico, Rhode Island and South Carolina, there is no inheritance tax. The tendency to place a large tax on bequests to near relatives is illustrated by the laws of Arkansas, where it is 24 per cent on $1,000,000; Idaho, 15 per cent on $1,000,000; Indiana, Wisconsin and West Virginia, 15 per cent on $500,000; Nevada, 25 per cent above $500,000; North Carolina and North Dakota, 15 per cent above $50,000; Texas, 12 per cent above $500,000, and Washington, 12 per cent above $100,000. Inheritance laws have in the United States occasioned much discussion and litigation, but their justice and utility have been testified to by experience and the decision of the law courts. The economists of the present and other periods have seen the scientific propriety of such legal provisions, and have noted the uniformity with which they deal with all classes of the financial community.

INHIBITION, (1) a writ from a higher to a lower court, as an ecclesiastical court in England, forbidding further proceedings; also, in English law, a command, as from a bishop, to a minister to cease performing ministerial functions. (2) In Scots law, an order restraining an heir from contracting debts affecting injuriously the rights of others in the heritable property. It is sometimes used also in Scots law in the sense of an order secured by a husband forbidding the giving of credit by another to his wife. It was formerly used in English law as synonymous with writ of prohibition.

INIA, a genus of toothed cetaceans similar to dolphins, but placed on structural grounds in the allied family *Platanistidæ,* with the freshwater dolphins of the Ganges and the La Plata. The single species (*I. groffrensis*) is called bouto and tucuxi, and is found in some of the upper tributaries of the Amazon, and in the lakes near the Cordilleras. It measures about eight feet in length, has a long cylindrical snout with stiff hairs, and a very slight dorsal fin. It feeds chiefly on fish, and is hunted for the sake of its oil.

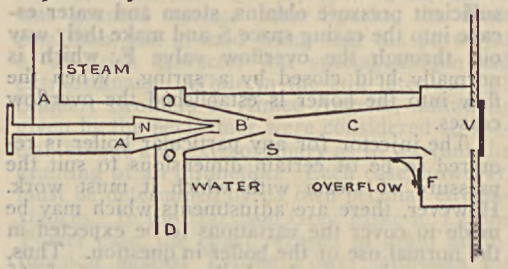
INITIATIVE. The initiative and the optional referendum, which originated in Switzerland, were introduced in the United States to obtain for the voters as a whole a more direct participation in legislation and a more immediate control of the business of government; the movement gained headway rapidly because the opinion prevailed in many sections that State legislatures were no longer representative of the people but were dominated by political rings and moneyed interests. While the referendum (q.v.) is effective in killing pernicious legislation and acts as a preventive to the enactment of such laws, the initiative affords a remedy for a legislature's indifference to public needs and its persistent refusal to pass legislation urgently required, if opposed by a corrupting lobby or other hidden influences. The initiative has long been in operation in Switzerland, originating in the "direct democracies" of the smaller cantons where any voter may require that his proposition be submitted to popular vote. In the larger cantons a certain proportion of the voters must favor the initiation of a legislative measure before it can be placed before the electors. In 1891 the Confederation adopted the initiative as a method of proposing constitutional amendments. The method was first introduced in the United States by South Dakota in 1898, but its principal use has been in Oregon which State in 1902 adopted a constitutional amendment providing that upon petition by at least 8 per cent of the electors who voted for justice of the Supreme Court at the last regular election (which petition must be filed with the Secretary of State four months before a general election), a proposed measure must be submitted to popular vote and must become law if favored by a majority of those who voted upon the measure. In 1901 Illinois passed a law stipulating that upon petition of 10 per cent of the registered voters, a given proposal, such as a "question of public policy" must be submitted to the voters of the whole State. Delaware and other States have enacted similar laws, which might be termed an "advisory initiative." These States were followed by Nevada (1905 and 1912), Montana (1906), Oklahoma (1907), Maine (1908), Missouri (1908), Arkansas (1910), Colorado (1910), Arizona (1911), California (1911), Nebraska (1912), Washington (1912), Idaho (1912), Ohio (1912), Michigan (1913), North Dakota (1914), Mississippi (1916), while Utah (1900) and Idaho (1912) provided for it but their legislatures have not passed the necessary enabling acts. New Jersey is experimenting with the system in cities, and Minnesota rejected it in 1916. In some States the practice is limited to the initiation of ordinary legislation but in other States constitutional amendments may be proposed in the same way, while most States have coupled this measure with the referendum, which provides for submission of the proposed legislation to popular vote. The initiative and referendum have taken their places beside direct primaries, the presidential preference primary, the recall of elective officials, woman suffrage, the short ballot, etc., as an effective means of enforcing the popular will as opposed to that of political bosses; but the initiative is somewhat difficult and cumbersome in its operations and, save in Oregon, has been sparingly employed. While in many States a large portion of the laws subjected to popular vote have been defeated, in Oregon nearly 50 per cent so submitted have been ratified, including a corrupt practices act, a general direct primary law, a workmen's compensation law, and others of vast importance. (See Referendum; Recall; Elections; Primary, Direct). Consult Beard, C. A., and Schultz, B. E., 'Documents on State-wide Initiative, Referendum and Recall' (New York 1912; gives text of laws of various States); and the bibliography given under the article Referendum.

INJALBERT, an'zhal'bar, **Jean Antoine,** French sculptor: b. Béziers, 1845. He received his artistic education under Dumont and in 1874 was awarded the Roman Prize for his 'Douleur d'Orphée.' In 1877 he exhibited at

the Salon a huge bas relief 'La Tentation,' and in the following year a 'Christ on the Cross,' now in the Rheims Museum. Injalbert has the gift of imparting life to his work and a wonderfully rich imagination. His 'Titian' surmounts a great fountain at Béziers. His 'Hippomène' is in the Luxembourg. Other works are 'L'Hérault, l'Orb, le Lez,' in the vestibule of the prefecture of Montpellier, the two groups of 'Enfants aux lions' also in Montpellier; the façade of the theatre of Béziers; figures on the Pont Mirabeau of Paris; the Moliere monument at Pézenas; the 'Fronton du Petit Palais' at the Paris Exposition of 1900.

INJECTOR, a mechanism for feeding water into a steam boiler while it is in operation, through the force of its own steam. The action of this device is based on that principle of hydrodynamics in virtue of which the velocity of a moving body of water or other liquid may be transmuted into pressure, and vice-versa, by proper arrangements of conduits and apertures.

In the injector a jet of steam, issuing from the boiler at a velocity of from 1,500 to 3,500 feet per second (depending upon the boiler pressure), is passed through a conical nozzle, indicated in the diagram by the letter A, from which it passes into another cone-shaped tube B. The open space O around the cone A is connected freely with the water-supply pipe D. This space may be filled with water by gravity from a reservoir above its level; or the action of the injector may be so arranged that through the exhausting of the air in B and O by the jet of steam a vacuum is produced and water may be thus "sucked" up from a well below, if the lift is not more than 15 to 18 feet. The rush of steam through the conical "combining tube" B drags along with it a conical shell of water lying next the walls of B and encasing a cone-shaped body of steam in its centre. As the



moving steam and water are choked at the apex of B, the steam is compressed, in part condensed and in part absorbed by the water, which takes up its velocity to a large degree and rushes into the apex of the conical tube C. Here the flare of the cone is in the opposite direction and as the column of water moves forward into this tube its velocity lessens as the tube grows larger, and is resolved into pressure, which presently becomes greater than the steam pressure in the boiler by which the

check valve V is kept closed. The valve V then opens and permits the water in C to flow through. At this instant the varying pressures throughout the injector come to an equilibrium, based on the condition of that pressure at which the water flows freely from the injector into the boiler — and that condition continues indefinitely as long as the steam pressure in the boiler remains uniform. Previous to the establishing of the steady flow, that is, before sufficient pressure obtains, steam and water escape into the casing space S and make their way out through the overflow valve F, which is normally held closed by a spring. When the flow into the boiler is established the overflow ceases.

The injector for any particular boiler is required to be of certain dimensions to suit the pressure of steam with which it must work. However, there are adjustments which may be made to cover the variations to be expected in the normal use of the boiler in question. Thus, steam issuing at the boiler pressure of 65 pounds may be made by the proper configuration of the conical tubes of the injector to exert a pressure of 90 pounds at the check valve into the boiler. While this pressure is too high for the feeding in of a normal supply of water — that required to replace the water which the boiler evaporates into steam from hour to hour — the pressure in the injector may be modified to a degree by the needle valve N in the steam supply pipe, and the discharge of the injector into the boiler regulated to a nicety.

The injector works well with water of a moderate temperature, that is, about 75°; with water above 110° it will not work at all.

The injectors most in use are of the non-automatic type, although the automatic sorts are coming more and more into favor. There are also some forms with two injector tubes working into the one discharge chamber which feeds the boiler. This latter type is preferable where the injector is operated with the exhaust steam (of high-pressure engines) which requires a larger steam supply and a larger area in the steam orifices to do the work.

The accompanying diagram is intended only to show clearly the principles on which the injector is able to perform its duty. For a study of the adaptations of these principles the reader is referred to 'The Practice and Theory of the Injector,' by S. L. Kneass (New York 1910), or Kent's 'Mechanical Engineers' Pocket Book' (New York 1916). Consult also Nagel, O., 'The Transportation of Gases, Liquids and Solids' — by jet machines (New York 1909).

INJUNCTION, a writ issued by a court of equity, bidding, or forbidding, a person or persons to do a certain thing. The injunction originated in Roman law, and was anciently known as an interdict, a name it still bears in Scottish practice. It was introduced as a remedy for some of the abuses of common law, and as a preventive, when evasion of common law provisions seemed possible. It is to-day one of the most potent of the legal remedies of an equitable character which stand on the statute books.

There are three main divisions in the purposes for which a writ of injunction is issued. A writ may be prohibitive, protective, or restorative. In the first place it may forbid the commission of certain acts of a civil nature which are charged with injustice. Second, it may be so framed as to protect such civil rights of an individual or a corporation as seem to be threatened. Third, it may order the restitution or restoration of such rights as have unlawfully been taken away from an individual or a corporation. These characters of the writ have been clearly expounded by Blackstone, as follows:

"This writ may be had to stay proceedings at law, whatever stage they may have reached; to restrain alienations of property *pendente lite*, and tenants for life and others having limited interest from committing waste. It may be granted to restrain the negotiation of bills of exchange, the sailing of a ship, the transfer of stock, or the alienation of a specific chattel, to prohibit assignees from making a dividend, to prevent parties from removing out of the jurisdiction, or from marrying, or having any intercourse, which the court disapproves of, with a ward. The infringement of a copyright or a patent frequently calls for the exercise of this beneficial process; which may also be had to restrain the fraudulent use of trade marks, or of the names, labels, or other indiciæ of the makers or vendors of goods and merchandise, and in a large class of cases, far too numerous to be mentioned here."

The first two kinds of injunction are most commonly used, and a familiar example of the prohibitory writ is that which orders the abatement of a nuisance. A railroad which lays tracks without first gaining the right of way may be compelled by injunction to remove them. By such a writ patent rights, copyrights and trade marks are secured from infringement, or proceedings in a court of law are stayed. Sometimes a court of equity issues an injunction prohibiting litigants within its own jurisdiction from prosecuting a suit in another jurisdiction; for example, a United States court may restrain creditors for suing in State courts for the enforcement of their claims against a bankrupt, and reserve the disposition of his estate to its own jurisdiction. A court of equity only issues a writ of injunction when a remedy of law appears inadequate to give the wronged party the complete relief to which he is entitled. Thus in recent cases the courts have issued writs forbidding labor agitators and others from inducing or coercing workingmen, in such a way as to bring on a strike to the injury and damage of employers, who might thus be induced to sacrifice their rights in order to escape ruin or irreparable loss.

An injunction in the United States may be preliminary or perpetual. A preliminary writ is sometimes styled interlocutory, as it is issued *pendente lite*. The preliminary writ may be made perpetual, if, after arguments made and heard, the court decides that the grounds advanced for the continuance are valid, and have been so proved by evidence. Failure to obey an injunction is punishable as a contempt of court (q.v.). Consult Beach, C. F., 'Treatise on the Law of Injunctions' (New York 1895); High, J. L., 'Treatise on the Law of Injunctions as Administered in the Courts of the United States and England' (Chicago 1905); Joyce, H. C., 'Treatise on the Law Relating to Injunctions' (3 vols., Albany 1909); Kerr, W. W., 'Treatise on the Law and Practice of Injunctions' (4th ed., London 1903).

INJUNCTION, Government by. See GOVERNMENT BY INJUNCTION.

INJUNCTION, Theatrical, a term applied to a mandate issued by a court of equity, to compel or prevent the performance of some act for which money damages would not properly compensate the injured party. Relief by injunction in matters pertaining to theatricals is probably more frequently sought than in any other business or profession, and precedents in law established in this class of cases have become of considerable importance. At first, courts of this country and England refused to grant injunctions against actors for the purpose of compelling them to perform their contracts, a learned justice saying: "The court could not regard as law the old adage that 'a bird that can sing and will not sing must be made to sing.'" But latterly, when the service of an actor became recognized and it was made to appear clearly that an actor or singer, by intelligence, education and other artistic accomplishments and talents, was of extreme importance to one who had invested money in the production of a play or opera it was held that a court of equity would by injunction enforce a covenant in a contract. But this has simply gone to the extent of compelling a fulfilment of the contract, or forcing the artist to remain idle during its term. The services of every actor will not be enjoined. He must actually possess some exceptional merit, so that his services may be termed special, unique and extraordinary, and it must be shown they cannot be fulfilled by any other person without injury to the employer. In the case of Lumley *v.* Wagner, the courts of England enjoined Johanna Wagner, a prominent prima donna of the early 50's from appearing at Covent Garden Opera House, London, in violation of her contract with Lumley; and then for the first time the British courts asserted their authority over contracts of actors, and granted an injunction forbidding her rendering professional services for any but her original employer.

In the United States, the Federal courts recognized the right of a manager to have the exclusive services of his employee, and in McCall *v.* Braham an injunction was granted which prevented Lillian Russell from violating her contract. In the State courts, the case of Augustin Daly *v.* Fanny Morant Smith (49 How. Pr. 150), Superior Court Justice Freedman also appreciated the fact that the ancient rule had been abrogated and the modern one compelling actors to live up to their agreements, as other individuals, was there enforced. The contract must unquestionably be fair. The rights of both parties to it must be equal. In other words, if the contract gives the manager the right to terminate it by giving notice before the expiration of the contract, a like right of termination must also be given the actor; and as stated before, the actor's services must be special, unique and extraordinary. In this latter connection, it seems uncertain where to draw the line. In the case of Carter *v.* Ferguson the court refused to grant an injunction to Mrs. Leslie Carter against William J. Ferguson, an actor, saying that his services were not so special and unique as to warrant a court of equity's interference. In Charles Hoyt *v.* Loie Fuller, the court granted an injunction against the dancer, holding that a serpentine dance in the performance of which she became famous, warranted the court's interference by injunction. In George Edwardes, the London manager, *v.* Cissie Fitzgerald, the New York Supreme Court granted an injunction against Miss Fitzgerald, on the theory that a certain wink of her eye used in a play was of special merit, and a drawing card. In Harris *v.* Sparks, an injunction was granted against John Sparks, the Irish comedian, the ground being that his portrayal of an Irish character was special, unique and extraordinary. While in the still later case of Shubert Brothers *v.* Aimee Angeles, imitations given by the performer were considered so special, unique and extraordinary as to warrant the granting of an injunction. Each case, however, must be determined by its own peculiar circumstances. In the Harrison Grey Fiske *v.* Tyrone Power case, the court refused to grant an injunction against Tyrone Power, although his ability as an actor was exploited in the newspapers, on the ground that his services were not so special, unique and extraordinary as to justify an injunction. But in guarding the rights of an actor, the courts will see that no advantage has been taken of him by the manager, and that the manager for whom he is to perform is of such financial responsibility as to insure the salary of the actor. In the case of Rice *v.* D'Arville, Edward E. Rice, the theatrical manager, sought to restrain Camille D'Arville from performing for others; but on the defense that Rice was insolvent and indebted to her on a previous contract, Justice Oliver Wendell Holmes, then of the Massachusetts Supreme Court, would not compel her to perform for Rice.

Injunctions in the theatrical profession are not confined to actors and actresses, but are often invoked to prevent the piracy of a play or the use of a name. Where a play or a scene from a play has been copyrighted, the Federal courts alone have jurisdiction of the matter, and will by injunction prevent anybody from performing or producing it as their own. When there has been no copyright the common law protects the work, as well as its title; and the use of a similar name, or a name which is apt to deceive the public into the belief that it is the one already used by an author, will likewise be enjoined. An instance is the case of Charles Frohman *v.* Arthur Fraser, where the use of the title "Sherlock Holmes" was enjoined, this name having been adopted by William Gillette as the title of a play, notwithstanding the name had been used by A. Conan Doyle as the title of his novel. In that case the court held that Mr. Gillette having first used the name in connection with a theatrical production was entitled to all emoluments arising from it. Notwithstanding the numerous attempts to avoid the principles of law applicable to this class of cases, it matters not whether it is the actor who is involved or the theatrical manager, the American courts are humane, equitable, just and careful, and invariably zealously guard the interests of those engaged in the theatrical profession, as well as those engaged in any commercial business. See INJUNCTION; GOVERNMENT BY INJUNCTION; COURT; EQUITY; CHANCERY; CONTEMPT; LAW, etc.

INJURIES, Industrial. See ACCIDENTS, CAUSES AND PREVENTION OF; WORKMEN'S COMPENSATION.

INJURY, in law, an act by which the rights of another person or of the state are violated and for which the party whose rights are so invaded may institute action for damages against the perpetrator. Wrongs called *damna absque injuria* are those acts while injuring another do not permit the latter the right to enter an action, there being no remedy for such acts. See CRIME; CRIMINAL LAW; EQUITY; TORT.

INK, a colored liquid used for writing and printing. It comprises various classes, as writing and copying, black or colored, India, printing and lithographing inks.

For long ages past the best black writing-ink has been made by mixing together solutions of nutgalls and of ferrous sulphate of iron, known as green vitriol, and holding in colloidal suspension, by aid of a gum, the colored substance produced. The gallo-tannic acid present in a freshly prepared solution of galls, upon exposure to the air, changes gradually largely into gallic acid, and the protoxide of iron changes into peroxide. The color of this changed product is much deeper than that of the original mixture. It has been found that the permanency of the writing is greater if the ink is used before this conversion is fully completed. The change is held in check by having present in the ink a slight amount of some free volatile acid, such as hydrochloric. The trace of acid also serves to hold the iron color in the state of colloidal suspension or solution. The moulding to which such an ink is liable is checked by adding to it a trace of some antiseptic, such as carbolic acid. All known commercial substitutes hitherto used for nutgalls in black writing-ink produce a fluid somewhat inferior to that from nutgalls.

An exhaustive scientific investigation of the chemistry of ink to determine the best ingredients and the proportions to be used of the same for the producing of the most permanent black writing-ink has been made in Germany by Osw. Schluttig and Dr. G. S. Neumann, and published in their work on 'Die Eisengallustinten,' issued by Zahn & Jaensch of Dresden in 1890. Their conclusions were followed in preparing the specifications for the official "Standard Record Ink" required under the laws of Massachusetts to be used on all the public records in that State. The same specifications have since been adopted by the United States Treasury for the ink used in that department. This ink has also been adopted by the Danish government for its official records. The specifications, which were prepared by Dr. Bennett F. Davenport of Boston, as ink expert for the State of Massachusetts, it is to be noted are for the required quality of the ink, and not for the compounding of it. The specifications are as follows:

It must be a gallo-tannate of iron ink, not inferior in any essential quality to a typical standard for comparison which has been properly prepared after the following formula, in which all the ingredients are of the quality prescribed by the United States Pharmacopoeia, and the per cent of true acid present in the sample of tannic acid used has been determined by the Loewenthal and Schroeder method.

Take of pure, dry Tannic Acid, 23.4 parts by weight; crystal Gallic Acid, 7.7 parts; Ferrous Sulphate, 30.0 parts; Gum Arabic, 10.0 parts; diluted Hydrochloric Acid, 25.0 parts; Carbolic Acid, 1.0 part; Water, sufficient to make up the mixture at the temperature of 60° F. to the volume of 1000. parts by weight of water.

Inks submitted will be subjected to the following tests, as compared with the typical normal standard ink described above: (1) A fluid ounce allowed to stand at rest in a white glass vessel, freely exposed in diffused daylight for two weeks to the light and air, at a temperature of 50° to 60° F., protected against the entrance of dust, must remain as free from deposit upon the surface of the ink or on the bottom or sides of the vessel. (2) It must contain no less iron, and must have a specific gravity of 1.035 to 1.040 at 60° F. (3) It must develop its color as quickly. (4) After a week's exposure to diffused daylight the color must be as intense a black when used upon the standard record paper, and it must equally resist changes from exposure to light, air, water, or alcohol. (5) It must be as fluid, flow as well, strike no more through the paper, nor remain more sticky immediately after drying.

To such an ink a slight amount of some one of the water soluble coal-tar colors is usually added to give the desired initial color to the ink when used in writing.

Cheaper grades of black writing-ink are produced by substituting for the nutgalls other tannin containing substances, or by using logwood. In these other iron salts, or salts of other metals are sometimes used, as of copper, aluminum or chromium. For special purposes some of these have certain advantages. For copying, for instance, the ink made from logwood with alum cake and chromate has the highest efficiency known. This ink, however, fades out after a few years' exposure to the open air and daylight.

Within modern times colored liquid solutions have come much into general use as inks, made up with aniline and other dyestuff colors. They are easily and cheaply made, flow nicely from the pen, and allow of a great variety as to choice in coloring, but none of them have the permanency of the ancient nutgall iron ink on exposure to light and air.

The usual basis of commercial marking inks, for use on textile fabrics, is some salt of silver. The permanent color of this ink is developed through the action of light, heat or some chemical, after the ink has been applied. The usual basis of India ink is an exceedingly finely divided solid carbon, mixed with a size to hold it in suspension when the ink is prepared for use by being ground up with water. (See INDIA INK). Printing ink consists of dry pigment, black or colored, ground very fine and mixed with varnish and a few minor chemicals as it may be desired for various purposes. For black printing ink, lampblack and linseed oil were originally employed, but gas-black has taken the place of the former, and the scarcity and high cost of linseed oil has led to much substitution; one of the most common is rosin oil. For pigments, the inorganic or earthy bases are preferred, but of late years a line of coal-tar products has been evolved that yield exceedingly brilliant colors though less permanent than the earth bases. Pigments require very careful grinding. The mills are water-cooled, but nevertheless heat under the pressure and friction on the rolls when grinding is continued too long, to remove the last vestige of grit; the ink thickens, and becomes so pasty that it has to be thinned down before it will flow through the fountain of a printing press. This thinning process tends to lighten the color, that is render a dense black slightly gray. Manufacturers of printing inks are required to produce very thin, cheap ink for rapid printing on newspaper presses, and whole series of better grades of black adapted to presses operating at speeds varying from 500 to 20,000 impressions per hour. They are also called upon to supply all conceivable shades of color in all qualities, and adapted to all varieties of paper. The result is an almost infinite number of grades and kinds of ink for typographic and lithographic work. The temperature of a press room much affects the working of ink. A desirable ink must not dry readily on the type from the ink rollers, but must dry quickly on the paper. To hasten drying, the ink makers insert material called a "dryer," and in recent years it is common in high-grade printing to pass the freshly printed sheet quickly over a gas flame to set the ink. Previous to the World War, the best colors for inks came from Germany. When importation ceased, American manufacturers set to work, and within two years a very fine large line of coal-tar colors of home make were on the American market.

INK DRAWING. See ART DRAWING.

INKBERRY, or WINTERBERRY, an evergreen shrub (*Ilex glabra*) of the holly family native to the Atlantic coast from Massachusetts to Florida, also to Alabama and Mississippi. Its slender and flexible stems are two to four feet high and its leaves, about an inch in length, are lanceolate, of leathery texture, and present a shining upper surface. It bears small, very black berries which are valued for decoration. Formerly its bark and leaves were used medicinally, especially in fevers.

INKERMAN, ĭnk-ĕr-măn', Russia, a village on the site of a ruined town in the Crimea, at the head of the harbor of Sebastopol, 35 miles by rail southwest of Simferopol. It gives its name to the sanguinary battle fought on the heights overlooking the town, on 5 Nov. 1854, when the Russians unexpectedly attacking the British camp were repulsed with great slaughter, losing in killed 3,000 and in wounded 6,000, the loss of British and French allies being 850 killed and 3,500 wounded.

INLAND WATERWAYS. Detailed descriptions of the navigable streams, lakes, bays and canals of the United States are given elsewhere in this Encyclopedia under WATERWAYS OF UNITED STATES. Most of these waterways have been utilized for a long time, and in fact, had greater use in years past than under present conditions of competition of rapid railway service. However, the United States Congress in every session makes large appropriations in the River and Harbor Bill for waterway improvements and there is great general interest in providing suitable ship canals to develop water traffic in various directions. One of the most prominent projects is that of a continuous inland water route along the Atlantic Coast from Massachusetts to the Gulf of Mexico. The "Atlantic Deeper Waterways Association" with large and influential membership has yearly conventions (9th in 1916) to urge that the government should make provision for this project. The plan is to deepen canals now in existence and dig some new ones, about 131 miles in all at an estimated cost of $50,000,000. There can be no question as to the importance of such a waterway to facilitate coastwise commerce and in time of war it might be a most useful avenue for the movement of supplies especially if offshore traffic should be menaced by an enemy.

The advantage of such an inland route is well shown by the cost of shipwrecks along the Atlantic Coast in the decade from 1900 to 1910; it is estimated that there were 4,700 wrecks in this time with loss of 2,200 lives and destruction of about $40,000,000 of property. The unfortunate congestion of freight on railroads in 1916–18 has done much to revive interest in inland waterways and brought conviction that they are a necessary addition to our transportation facilities. Much of the desire for speedy transit of freight is unwarranted and wasteful of fuel and energy. Railways and waterways must work in accord. Suitable legislation can remove hurtful railroad competition so that capital can be safely invested in waterway projects with prospects of reasonable profits. Canada and New York State both present excellent object lessons of the great advantage of inland waterways for the development of local commerce. Europe with her many extensive canal systems has long since demonstrated the utility of waterways. Low cost of transportation is a most important factor in competition along nearly all commercial lines and many industries are crippled by expense of long land hauls of supplies or products. The low cost of wheat transportation mainly by water from the great fields of western Canada to Europe gives Canada considerable advantage in this item alone.

The Inland Waterways Commission created by President Roosevelt on 14 March 1907, consisted of Sen. Theo. E. Burton, Chairman, Sen. F. G. Newlands, Sen. Wm. Warner, Hon. John H. Bankhead, Gen. Alex. Mackenzie, W. J. McGee, F. H. Newell, Gifford Pinchot and H. Knox Smith. Its purpose was to prepare a report on a comprehensive plan for the improvement of the rivers of the United States to increase their usefulness as navigable waterways. The investigation of conditions for flood control and water power development were important features of the work. Various reports were prepared and Congress was recommended to make provision for various improvements, some of which have been incorporated in subsequent river and harbor bills. It is estimated that there are on the mainland of United States about 25,000 miles of navigated rivers and this amount could be doubted by improvement. There are 2,500 miles of canals, many thousand miles of regularly navigated waters in lakes and bays, and more than 2,500 miles of sounds, bays and bayous. Some of these water bodies can be connected by canals to form inner passages paralleling the Atlantic and Gulf coasts.

In the last few decades in the United States most inland waterways have not been economically successful excepting in giving access to certain ports. Long distance river and canal transportation under the blighting effect of railroad opposition has steadily declined. Most

of the canals have passed into the control of railroad companies and the rivers are closely paralleled by railroad lines. The general desire for fast freight service has had a powerful influence. Proper regulation of this competition and the deepening and other improvement of the waterways so that they can be utilized more economically will change this condition and they will become an important factor in cheap transportation. Canada with a 21-foot waterway from ocean to Great Lakes has a notable commercial advantage. The great railroad congestion in 1917–18 could have been avoided or greatly diminished by waterways suitable to carry part of our great freight burden. It has been estimated (by Mulhall) that in Europe there are more than 77,000 miles of navigated waterways of which 13,293 miles are canals, the latter costing considerably more than $1,000,000,000. South America has important inland waterways and for centuries China has had thousands of miles of canals which afford cheap transportation over a large part of the country. Floods are an adversary of river waterways, mainly in damage they cause to the channel but they can be controlled by reservoirs and reforestation. These latter features of development also have great economic advantage in affording water power and adding to lumber resources. Another incidental improvement in some areas is the drainage and reclamation of swamp lands, affording increased acreage for farming and bettering health conditions.

N. H. Darton,
United States Geological Survey.

INLAYING is the art of producing an ornamental surface by inserting varicolored forms and substances and reducing the whole to a smooth uniform condition, but with a pattern formed by the contrasting material introduced. Its essential difference from mosiac work (q.v.) is that mosaic is mainly made up of very small surfaces, while inlaid work is additional to a surface, as of wood on ivory, already existing, to add to its beauty. Various kinds of metal or wood, or pearl, ivory, etc., are employed in this process, which is now applied chiefly to the production of ornamental articles of furniture. When wood of one color is inlaid with others of different colors, as in ornamental devices in flooring, it is generally called parquetry, the various pieces of wood being usually disposed in regular geometrical figures. Marquetry or marqueterie is simply the French term for inlaying. The art of inlaying iron or steel with other metals, as gold or silver, is called damascening. Buhl and reisner work, once highly prized, have lost much of their celebrity. The former took its name from Buhl, an Italian resident in Paris in the reign of Louis XIV, and the latter was designated after Reisner, a German who not long after settled in the same city. Buhl for the most part inlaid brass on tortoiseshell, Reisner a dark wood on a tulip-wood ground. The usual instrument for cutting out veneers for inlaying is a fine saw, mounted in a bow or arched handle, and worked in short quick movements. Three or four veneers are sometimes cut simultaneously in this way. Inlaying with stone, in which the Florentines have long excelled, is called *pietra dura,* and differs from mosaic in having the holes not cut through the ground, which is commonly of black marble, but only to a regulated depth. An Indian variety of inlaying, in which the inlaid metal occupies more of the surface than that which forms the ground, is called *Kuftgari;* and in another variety, *Tutenague* or *Bederywork,* small pieces of silver are hammered into spaces previously cut in the ground, which consist of one part of copper to four of pewter, and is thus both hard and easily cut.

INLIER. See Outlier.

INMAN, Henry, American artist: b. Utica, N. Y., 20 Oct. 1801; d. New York, 17 Jan. 1846. From early boyhood he manifested a taste for art, and in 1814 J. W. Jarvis, the portrait painter offered to receive him as a pupil, and he was bound an apprentice for seven years. Upon the conclusion of his apprenticeship he devoted himself to portrait painting. In 1832 he married and settled at Mount Holly, near Philadelphia. He was one of the founders of the National Academy of Design and one of its vice-presidents. Among his most characteristic portraits are those of Chief Justice Marshall, Lafayette, William Penn, Martin Van Buren, Fitz-Greene Halleck, J. J. Audubon, Horace Binney, Nicholas Biddle and Bishop White. Many of his portraits are to be found in public buildings in New York, Albany and Philadelphia. He painted also landscape, genre and history. The best known of these are 'The Boyhood of Washington'; 'The News Boy'; 'Rip Van Winkle'; 'Mumble the Peg'; 'Dismal Swamp'; 'Dundrennan Abbey'; 'October Afternoon.' In 1844 he visited England, where he was the guest of Wordsworth, whose portrait he painted, and at whose suggestion he executed his 'Rydal Water,' near the poet's residence. During his residence in England he also painted portraits of Dr. Chalmers, Lord Chancellor Cottenham and Macaulay. Inman was not only one of the most prominent American painters of his time, but a man of great personal magnetism, a keen lover and student of nature, a clever conversationalist and after-dinner speaker, as well as a contributor to and illustrator of the magazines of his days. Consult Van Norden and King, 'Catalogue of Works by the late Henry Inman, etc.' (New York 1846).

INN, a river of Europe which issues from a lake at the foot of the Piz Longhino in the Rhætian Alps, at an altitude of about 8,000 feet, forms a series of small lakes, the best known of which is that of Saint Moritz, then flows

northeast through the deep and narrow valley of the Engadine, in the Swiss canton of the Grisons, enters the Tyrol at Martinsbruck, passes Innsbruck, Hall, and Kufstein, and shortly after enters Bavaria. At Mühldorf it turns east till it receives the Salza, where it begins to form the boundary between Austria and Bavaria, and joins the right bank of the Danube at Passau, after a course of over 300 miles. On account of its rapid current it is of little importance as a navigable river, but it is used extensively to bring timber rafts down to the Danube from the well-wooded mountain regions of its upper section. Consult Greiuz, R., 'Von Innsbruck nach Kufstein Eine Wanderung durch das Unterinntal' (Stuttgart 1902).

INN AND INNKEEPER. In Great Britain inns are houses where travelers are furnished, for the profit of the provider, with food and lodging, and may be set up without license by any person, provided he refrains from selling excisable liquors, which, of course, require a license. Hotels, public-houses, taverns, victualing-houses and coffee-houses are all inns when the keepers of them make it their business to furnish travelers with food and lodging; otherwise they are not. In the United States the equivalents of inns are the road-houses, hotels in cities and saloons in rural districts. See Hotel; Hotels in America; Taverns.

INNATE IDEAS, in epistemology and in metaphysics, are ideas as of right, wrong, freedom, immortality, and of God, supposed by some to inhere in the mind, in which case they are opposed to acquired ideas, and synonymous with inborn or inherited ideas. But innate has also another meaning. Not infrequently it is understood as synonymous with natural, essential, necessary, abstract, pure, a priori, transcendental, or with universal. In the sense of inborn, innate conveys a notion of something temporal. At the outset of this article, it may be admitted, without hesitation, that no inborn ideas exist at all. But likewise, it must be granted that innate ideas, as synonymous with the Kantian a priori, as of God, etc., not only exist, but they have both objective validity and are among the most certain cognitions grasped by the mind of man. For the formal sciences, pure mathematics, logic and pure natural science, are not inborn or inherited, but yet are most certainly a priori, and therefore innate in one (the legitimate second sense) of the word. The term innate as applied to ideas was not, as some say, first employed by the philosopher Descartes. Long before his works appeared, innate, as applied apparently to inborn ideas, was in common use in England, and it is to be found in a poem of Sir John Davis, published four years before Descartes was born. The title of this poem tells us expressly that there are innate ideas in the soul. Then with the taunting question put to Descartes the question of innate ideas enters modern philosophy. The prevailing misapprehension with respect to the doctrine usually ascribed to this philosopher can only be accounted for by supposing that the opinions of Descartes have been more frequently judged from glosses of his nominal followers than from his own works. Among those who seem to have misunderstood Descartes was the lively but superficial philosopher Voltaire. As Descartes not only has been misunderstood by Voltaire, but also by a number of others, it may not be amiss to quote him (as the passage in which his elucidation of his conception occurs is very rare), and let the reader judge for himself.

"When I said that the idea of God is *innate* in us, I never meant more than this, that Nature has endowed us with a faculty by which we may know God; but I have never either said or thought that such ideas had an actual existence, or even that they were species distinct from the faculty of thinking. I will even go further, and assert that nobody has kept at a greater distance than myself from all this trash of scholastic entities, in so much that I could not help smiling when I read of the numerous arguments which Regius has so industriously collected to show that infants have no actual knowledge of God while they remain as yet unborn. Although the idea of God is so imprinted on our minds, that every person has within himself the faculty of knowing God, it does not follow that there may not have been various individuals who have passed through life without making this idea a distinct object of apprehension, and in truth, they who think they have an idea of a plurality of Gods, have no idea of God whatever." ('Cortesii, Epist.,' Pars. I, Epist. xcix). For Voltaire's misrepresentation of this idea of Descartes the reader may turn to Voltaire's "Letter 13," in his 'Letters on the English Nation.' A number of Dutch divines whose opinions differed widely from those of Descartes, found it convenient to shelter their solemn nonsense under his established name. No doubt some of Voltaire's strictures might have found an application there. It is probable too, as Hume says, that no more was meant by those who denied innate ideas than that all ideas were copies of our impressions. Dr. Cudworth, who felt that there are some ideas of the mind not stamped upon it from sensible objects without, and therefore which arise from the innate vigor and activity of the mind, enumerates a rather complete group of such innate ideas. He divides them as follows into two groups: (1) Ideas of wisdom, folly, prudence, imprudence, knowledge, ignorance, verity, falsity, virtue, vice, honesty, dishonesty, justice, injustice, volition, cognition, "nay," he says "of sense itself" as a species of cognition, and which is not perceptible as an idea by any sense. (2) Ideas of cause, effect, means, end, order, proportion, similitude, dissimilitude, equality, inequality, aptitude, inaptitude, symmetry, asymmetry, whole, part, genus, species, and the like.

Perhaps no word in philosophy has been responsible for more confusion than the word idea. In Plato what in logic is called an universal, that is the common nature which thought recognizes in different particular things. Nowadays it sometimes means an opinion, sometimes mental images and sometimes it appears merely as an element in a paraphrasis as in "have an idea of."

Some of the greatest names in European philosophy are associated with the discussion of the question of innate ideas. Besides those already mentioned are Newton, Clark, Malebranche, Lord Shaftesbury, Hobbes, Locke,

Hume, Leibnitz, Cousin and Kant. What the followers of Cousin term universal, necessary and absolute, those of Descartes designate as innate ideas. The difference between the philosophers is more verbal than real. Hobbes, indeed, in his zeal against Descartes, appears to have been not conscious of the fact that his conception of time as the mere "phantasm of before and after notion," along with the reason he gave for so saying, makes him approach more nearly the adherents of inborn ideas than even his opponent Descartes. In this respect the late Herbert Spencer, who seems puzzled by his very natural possession of abstract ideas approaches Hobbes very nearly. At bottom, however, no essential difference between the real sentiments of the more important disputants, as Locke and Descartes existed at all. Modern psychology has set the question at rest. The genesis of ideas is as follows: A sensory experience, with many other impressions like it, is realized in consciousness, and a sentient being has a sensation. Sensations become, in time, percepts. Many percepts of the same kind become concepts or ideas. From concepts abstractions are drawn. And among such abstractions our ideas of freedom, immortality, and even of God, are to be numbered. In other words, "nihil est in intellectu, quod non fuerit in sensu,— there is nought in knowledge, that was not born of the spirit."

INNER LIGHT, The, or INWARD LIGHT. A doctrine especially emphasized by the Quakers. The teaching is that within every soul there is a revelation of God. There is a revelation of God in Nature, there is a revelation of God in the Bible, but there is also the Inner Light revealing God. It may be only a seed and may not come to perfection, for its call may be denied. It differs from the Methodist doctrine of the witness of the Spirit in that it is recognized as always residing in the heart, while the witness of the Spirit comes from without through experience. It differs from the conscience, because its function is not to determine the difference between right and wrong but to illume the soul and make it aware of the presence of God. Consult Barclay, Robert, 'An Apology for the true Christian Divinity'; Bradford, Amory H., 'The Inward Light' (1905).

INNER RHODES, or INNERRHODEN. See APPENZELL.

INNES, in'ĕs, **Alexander Taylor,** Scottish jurist: b. Tain, Ross and Cromarty, Scotland, 18 Dec. 1833; d. Edinburgh, 27 Jan. 1912. He was educated at Edinburgh University, and was admitted to the Scottish bar in 1870. He was an authority on Scottish Church law and wrote 'The Law of Creeds in Scotland' (1867, and brought down to date in 1902); 'Church and State: A Historical Handbook' (1890); 'Studies in Scottish History' (1892); 'The Trial of Jesus Christ' (1899); 'Scottish Churches and the Crisis of 1907.'

INNES, Cosmo, Scottish lawyer and antiquary: b. Durris, 9 Sept. 1798; d. Killin, 31 July 1874. He received his education at the Edinburgh High School and at Glasgow and Oxford universities. In 1822 he passed as a Scottish advocate, became sheriff of Moray in 1840, and subsequently was appointed clerk to the Second Division of the Court of Session. In 1846 he was elected to the chair of history in the University of Edinburgh. He is best known, however, as the author of 'Scotland in the Middle Ages' (1860); 'Sketches of Early Scotch History' (1861) and volume I of 'Acts of the Scottish Parliament.' He published also a volume of lectures on 'Legal Antiquities' (1872), and was the author of several memoirs, including one of Dean Ramsay. Consult the memoir by his daughter, Mrs. Hill Burton (1874).

INNES, Thomas, Scottish historian: b. Drumgask, Aberdeenshire, 1662; d. Paris, 28 Jan. 1744. At 15 he was sent to Paris, where he studied at the College of Navarre and the Scots College, of which latter body his eldest brother was principal after 1682. Thomas received priest's orders in 1692, and after three years of mission work at Inveraven, Banffshire (1698–1701), returned to Paris, and became prefect of studies in the Scots College. To pursue his researches he paid a visit or two to England and Scotland; and Wodrow, who saw him at Edinburgh in 1724, describes him as "a monkish, bookish person, who meddles with nothing but literature." Withal, he was a staunch Jacobite, but no Ultramontane, and is said to have been tainted with Jansenism. He may justly be looked on as the precursor of Niebuhr and Niebuhr's successors; for his 'Critical Essay on the Ancient Inhabitants of Scotland' (2 vols. 1729) is much the earliest of all scientific histories. It was meant for an introduction to a 'Civil and Ecclesiastical History of Scotland,' one volume of which, coming down to Columba's death, he prepared for the press, while another, bringing down the narrative to 831, was left incomplete. Both were edited for the Spalding Club by Grub (Aberdeen 1853). The aim of the whole work was "to counteract the inventions of former historians (Hector Boice), and to go to the bottom of the dark contrivances of factious men (George Buchanan) against the sovereignty of our kings"; and though he thus wrote with a purpose, his honesty and acumen were such that the work retains a permanent value. Consult 'Memoir' by Grub; Chambers' 'Biographical Dictionary of Eminent Scotsmen' (Glasgow 1837); 'Dictionary of National Biography' (Vol. XXIX, London 1892); Forbes, 'An Account of the Familie of Innes' (compiled 1698; first printed, Aberdeen 1864).

INNESS, George, American painter: b. Newburg, N. Y., 1 May 1825; d. Bridge of Allan, Scotland, 3 Aug. 1894. His art education began in boyhood and when 16 years of age he learned map engraving. He first attempted nature sketching in 1843, when he showed such promise that he was admitted into the studio of Regis Gignoux, New York; but soon opened a studio for himself and through the liberality of a patron was enabled to visit Europe. After spending 15 months in Italy and one year (1850) in France he finally made his home at Eagleswood, near Perth Amboy, N. J. He was looked upon as the first among American landscape painters, and was not only a clever and imaginative interpreter of the scenery among which he lived, but a man of intellect, a thoughtful yet bold theorist on art subjects and an incisive critic. He had a keen

appreciation of American scenery, and the sky and atmosphere of the eastern States were sympathetically portrayed with an earnestness that recalls the sentiment of the Fontainebleau-Barbizon school. His early paintings are distinguished by conscientious care for detail, vivid perception of color, and the panoramic breadth of a bold and unconventional originality. After 1878 his style had ripened, and his technique grew simpler and less highly elaborated. He was willing to sacrifice all cleverness of touch in handling detail for the sake of portraying the emotion, or transitory effect of light and cloud in a landscape, the perturbation of storm or wind, the pageant of sunset, or the magic calm of a moonlight scene. In such productions his command of color was very remarkable. His pictures are much prized by connoisseurs, and when offered for sale command high prices. Five of them are in the Metropolitan Museum of Art, New York. Among the finest are 'Under the Greenwood'; 'Close of a Stormy Day'; 'Pine Groves of Barberini Villa'; 'An Autumn Morning'; 'Autumn Gold'; 'The Edge of the Forest'; 'Passing Storm'; 'Moonrise'; 'Winter Morning, Montclair, New Jersey.' Consult Caffin, C. H., 'American Masters of Painting' (New York 1902); Daingerfield, E., 'George Inness, The Man and his art' (New York 1911), and 'Fifty Paintings by George Inness' (New York 1913); Trumble, A., 'George Inness, a Memorial' (New York 1895).

INNESS, George, Jr., American painter: b. Paris, France, 5 Jan. 1854. He is the son of George Inness (q.v.), the landscape painter, whose pupil he was at Rome in 1870–74, and of Bonnat at Paris in 1875. He began to exhibit at the National Academy in 1877, and became a member of the National Academy of Design in 1899. In 1899 he obtained a gold medal at the Paris Salon. His manner is forcible, and skilful in color. His work includes landscapes and animal subjects, among them 'The Pride of the Dairy' (1878); 'Pasture at Chemung'; 'A Mild Day' (1887), and 'Morning on the River' (1902). A great deal of his later work has appeared in the *Century Magazine* with which he has been connected since 1913. He wrote 'The Life, Art and Letters of George Inness' (1917).

INNISFAIL, or Isle of Destiny, the name frequently applied to Ireland by the bards and sometimes also by Anglo-Irish writers.

INNISKILLING. See ENNISKILLEN.

INNOCENT, the name of 13 popes, as follows:

INNOCENT I, Saint: b. Albano; d. 12 March 417. He succeeded Anastasius I as bishop of Rome in 402. He supported Saint Chrysostom (q.v.) when the latter was driven from his see of Constantinople through the machinations of the Empress Eudoxia. Rome was pillaged by Alaric in 410, during his pontificate. He is commemorated by the Roman Catholic Church on 28 July. His correspondence is edited in Migne, 'Patrologia Latina' (Vol. XX).

INNOCENT II (GREGORIO DE' PAPI, or PAPARESCHI): b. Rome; d. 23 Sept. 1143. He was elected Pope in 1130 by a part of the cardinals, while the others elected Peter of Leon, who took the name of Anacletus. Innocent fled to France, where he was acknowledged by the Council of Etampes, by Louis VI, and soon after by Henry II of England; also by the Emperor Lothaire, who conducted him in 1133 to Rome, where he occupied the Lateran, while Anacletus occupied the Castle of Crescentius, the church of Saint Peter, and a large part of the city and maintained himself against Innocent until his death in 1138. He held the second Ecumenical Council in the Lateran, which condemned Arnold of Brescia and his heresy, declared all the decrees of Anacletus null, and excommunicated Roger of Sicily, who had supported the latter. Roger, however, obliged Innocent to acknowledge him as king, absolve him from excommunication, and invest him and his heirs with Apulia, Calabria and Capua. His letters are published in Migne, 'Patrologia Latina' (Vol. CLXXIX, Paris 1844–64).

INNOCENT III (GIOVANNI LOTHARIO CONTI): b. Anagni, Italy, 1161; d. Perugia, Italy, 16 July 1216. On the death of Celestine III (1198) he was unanimously elected at the age of 37. Innocent, in the vigor of manhood, endowed by nature with all the talents of a ruler, possessed of an erudition uncommon at that time, and favored by circumstances, was better qualified than any of his predecessors to elevate the Papal power. By his clemency and prudence he gained over the inhabitants of Rome, obliged the imperial prefect to take the oath of allegiance to him, and directed his attention to every quarter where he believed that a papal claim of property or of feudal rights existed. He concluded treaties with many cities of Tuscany for the mutual protection of their liberties and those of the Church, and soon obtained possession of the ecclesiastical states in their widest extent. He excommunicated Philip Augustus, king of France; laid the kingdom under an interdict in 1200 because Philip had repudiated his wife Ingeburga, and obliged the king to submit. He was still more decided in his treatment of John, king of England, who refused to confirm the election of Stephen Langton as archbishop of Canterbury. Innocent laid the kingdom under an interdict, and in 1212 formally deposed him. John was finally obliged to submit, resigned his territories to Rome, and received them as a papal fief from Innocent. All Christendom acknowledged the Pope's spiritual sovereignty; two Crusades were undertaken at his order, and his influence extended even to Constantinople. Innocent was one of the greatest popes and rulers. It has been said of his rule, as of that of Gregory VII, whom he most resembles, that in those times the power of the Pope was salutary as a bond of union for Europe, in which the still firmer bond of a common civilization and knowledge did not, as at present, exist. In 1215 he held a council, the fourth Lateran and twelfth general which passed the decree making confession and communion obligatory at Paschal time. Frederick II was acknowledged as German emperor, and the Franciscan and Dominican orders were confirmed. His correspondence is in Migne (Vol. CXIV–CXVIII). Consult Von Hurter, 'Geschichte des Papstes Innocenz III und seiner Zeitgenossen' (4 vols., 3d ed., Hamburg 1841–43); Luchaire, 'Innocent III' (Paris 1904–08); Mann, 'Lives of the

Popes in the Early Middle Ages' (London 1914).

INNOCENT IV (SENIBALDI DI FIESCHI): b. Genoa; d. Naples, 7 Dec. 1254. He was Pope from 1243–54 and was perpetually at feud with the German emperor Frederick and his successors. They came to terms in 1244, but these were misinterpreted and Frederick set out to capture Innocent. The Pope fled to Lyons where he called a general council to decide the issue (1245). It was not until after Frederick's death that Innocent was able to return to Rome (1253). Conrad IV, Frederick's successor, continued the strife, for which he was excommunicated in 1254. He died a few weeks later, and his cause was espoused by Manfred, his natural son, who, placing himself at the head of Moorish troops, defeated the Papal army in December of that year. Innocent survived this defeat by five days. He published a commentary on the Decretals of Gregory IX, first printed at Strassburg (1477). Consult Weber, 'Der Kampf Zwischen Papst Innocent IV und Kaiser Frederick II' (Berlin 1900).

INNOCENT V (PIETRO IDI TARENTASIA): b. Savoy, 1225; d. Rome, 22 June 1276. He was of the Dominican Order, taught at Paris, and became Archbishop of Lyons (1271). Shortly afterward he became Cardinal. His pontificate lasted only from 20 January to 22 June of the year 1276. The struggle between the Guelphs and Ghibellines occupied his short reign, as well as efforts to reclaim the Eastern Church for Rome. Innocent V published commentaries on the Bible and on the sentences of Peter Lombard. Consult Gregorovius, F., 'History of the City of Rome in the Middle Ages' (Vol. VI, London 1898); Pastor, L., 'History of the Popes' (Vol. I, London 1906); and Carboni, 'De Innocentio V, Romano Pontifice' (Rome 1894).

INNOCENT VI (ETIENNE D'ALBERT): b. Mons, France; d. 12 Sept. 1362. His pontificate extended from 1352 to 1362, and during this period the Papal residence was at Avignon. He was a man of great learning, and encouraged education and literature. Petrarch lived at his court for a time. Consult bibliography under INNOCENT V, above, and Pastor, L., 'Innocent VI et Blanche de Bourbon, lettres du pape' (ed. by Daumet, Paris 1901).

INNOCENT VII (COSMO DE' MIGLIORATI): b. Sulmona, Abruzzi, Italy, 1366; d. Rome, 6 Nov. 1406. He was Pope from 1404 till his death, but was opposed by the antipope, Benedict XIII, who held his court at Avignon. Consult Gregorovius, F., 'History of the City of Rome in the Middle Ages' (Vol. VI, London 1898).

INNOCENT VIII (GIOVANNI BATTISTA CIBO): b. Genoa, 1432; d. 25 July 1492. He was descended from a noble family of Genoa. Paul II made him Bishop of Savona, and he was appointed cardinal by Sixtus IV. He became Pope in 1484 and was for some time at war with Ferdinand of Naples and held the sultan Bajazet's brother Zelim a prisoner. He showed marked favoritism to the various members of his family. He made his natural son, who had been born to him before he began his ecclesiastical career, ruler of several towns near Rome, and married him to the daughter of Lorenzo de'Medici. For this favor on the part of the Medicis, he made the 14-year-old Giovanni de'Medici a cardinal. Consult Serdonati, 'Vita e fatti d'Innocenzo VIII' (Milan 1829).

INNOCENT IX (GIOVANNI ANTONIO FACCHINETTI): b. Bologna, Italy, 1519; d. 30 Dec. 1591. He studied law, and later was appointed bishop by Pius IV. After the Council of Trent, he became nuncio at Venice, which post he held for six years. Under Gregory XIII, he was cardinal, and was well favored by this pope's successors. He occupied the papal chair only from the 29th of October preceding his death. He published a number of works on philosophy and politics.

INNOCENT X (GIOVANNI BATTISTA PAMFILI): b. Rome, 7 May 1574; d. 6 Jan. 1655. In 1629 he was elevated to the cardinalate and became Pope in 1644. Under him the temporal and spiritual power of the papacy was greatly increased. In 1651 he condemned the Treaty of Westphalia and he formally condemned Jansenism in 1653. Consult Ciampi, 'Innocenzo X Pamfili e la sua corte' (Rome 1878); Hergenröther, 'Katholische Kirche und christlicher Staat' (Freiburg 1872).

INNOCENT XI (BENEDETTO ODESCALCHI): b. Como, Italy, 1611; d. 12 Aug. 1689. He served in his youth as a soldier in Germany and Poland, took orders later and rose through many important posts, became cardinal in 1645, and was elected Pope in 1676, on the death of Clement X. He was eminent for his probity and austerity; zealously opposed nepotism and simony, and restrained luxury and excess. He condemned the New Testament of Mons and several other Jansenistic works. He also anathematized sixty-five propositions drawn from the works of modern Causists and condemned Molinos and the Quietists. He determined to abolish the right of asylum exercised in Rome by foreign ambassadors; but Louis XIV would not yield to so just a claim, occupied Avignon, and imprisoned the papal nuncio in France; in consequence of which the authority of the Pope received a severe blow by the IV Propositiones Cleri Gallicani in 1682. These disputes were highly favorable to the English Revolution, as it induced the Pope in 1689 to unite with the allies against James II, in order to lower the influence of Louis XIV. Consult Gérin, 'Le pape Innocent XI et la révocation de l'Edit de Nantes' (in *Revue des questions historiques*, Paris 1878); id., 'Innocent XI et la révolution anglaise de 1688' (Paris 1876); Immich, 'Papst Innocenz XI' (Berlin 1900); Bryce, 'Holy Roman Empire' (New York 1911).

INNOCENT XII: b. Naples, 13 March 1615; d. 27 Sept. 1700. He became archbishop of Naples, a cardinal in 1681 and Pope in 1692. During his pontificate Louis XIV and the French bishops revoked the declaration of the French clergy, and submitted to the judgment of the Holy See in the matters in dispute during the pontificate of Innocent XI. Consult von Ranke, Leopold, 'History of the Popes' (Vol. II, London 1908).

INNOCENT XIII (MICHELANGELO CONTI): b. Rome, 15 May 1655; d. 7 March 1724. In 1695 he was made archbishop of Tarsus, and became a cardinal in 1707. He was also made bishop of Viterbo in 1712 and succeeded Clement XI in the papal chair in 1721.

INNOCENTS, Feast of Holy, variously styled Innocent's Day and Childermas, a festival generally observed on the 28th, but in the Eastern Church on 29 December, in commemoration of the massacre of the children at Bethlehem, "from two years old and under," by the order of Herod, with the purpose of destroying among them the infant Saviour. The Church of England at the Reformation retained it in its ritual among its anniversary festivals. Saint Cyprian refers to these children as martyrs, as does Saint Augustine with still greater explicitness. It is to them that the hymn of Prudentius, 'Salvete Flores Martyrum,' is addressed.

INNOCENTS ABROAD, The, a famous book of travels, by Samuel L. Clemens ("Mark Twain"). In a vein of highly original humor this widely-read book records a pleasure excursion to Europe, the Holy Land, and Egypt, in the sixties. Descriptions of real events and the peoples and lands visited are enlivened by more or less fictitious dialogue and adventures.

INNOMINATE ARTERY. See AORTA.

INNOMINATE BONE. See PELVIS.

INNS OF CHANCERY. Originally buildings or building groups in London set aside as residences for the clerks of the chancery courts. They were 10 in number but have long since ceased to exist as public offices, being now merely incorporated societies. See CHANCERY.

INNS OF COURT are certain societies in London exclusively invested with the right to call to the bar in England. The colleges of the English professors and students of common law are called inns, the old English word for the houses of noblemen, bishops and others of extraordinary note being of the same signification as the French *hôtel*. Societies of lawyers, which before the Conquest held their chief abodes for study in ecclesiastical houses, began to be collected into permanent residences soon after the Court of Common Pleas was directed to be held in a fixed place,—a stipulation which occurs in the great charters both of King John and Henry III. In these houses exercises were performed, lectures read and degrees conferred. The Inns of Court are each self-governing and all have equal privileges, and they are officered by benchers—members of standing at the bar—and stewards, and possess the power of disbarring members in case of serious misdemeanor. The inns have extensive ranges of buildings with suites of chambers generally occupied by barristers. Each inn maintains a chapel, the Inner and Middle Temple having the joint use of the Temple Church. The four Inns of court are: the Inner Temple and Middle Temple (formerly the dwelling of the Knights Templars, and purchased by some professors of law more than three centuries since); Lincoln's Inn and Gray's Inn (ancienty belonging to the earls of Lincoln and Gray). King's Inn, Dublin, the legal school in the Irish capital, and the Faculty of Advocates in Edinburgh, the Scottish law incorporation, perform analogous functions with the English inns of court in their respective countries.

INNSBRUCK, ĭns'brook, or **INNSPRUCK** (ancient ŒNIPONTUM; locally called SCHPRUCK), Austrian town and capital of the Tyrol, beautifully situated at an elevation of 1,880 feet, 59 miles south of Munich, on the banks of the Inn, near its confluence with the Sill, and almost in the centre of the valley of the Inn (Innthal), the sides of which are enclosed by mountains several miles distant, but so lofty (7,000 to 8,500 feet) as apparently almost to overhang the town. It consists of the town proper, situated on the right bank of the river, and of five suburbs. It is for the most part well built. The houses are generally of a limestone breccia and from four to five stories high, and built in the Italian style. The buildings most deserving of notice are the Hofkirche, containing the tomb of the Emperor Maximilian I, one of the most splendid monuments of the kind in Europe, though he himself is not interred in it; and the tomb of Hofer; the church of Saint James, with a painting by Lucas Cranach; the Jesuit church, considered the handsomest in the town; the Capuchin church, with good paintings; the new palace, built by Maria Theresa, a very extensive edifice, with gardens which stretch along the side of the Inn and form an excellent promenade; the old palace, in which the archdukes of Tyrol and several of the German emperors used to reside; the university, founded in 1677 and re-established in 1826, well endowed, provided with a great library of 260,000 volumes, botanical garden and cabinet of natural history and attended by about 1,300 students; a gymnasium and several other important educational establishments; and the museum, called Ferdinandeum, rich in all the productions both of art and nature within the limits of the Tyrol. The manufactures include woolen, silk and cotton tissues, gloves, mosaics, glass, etc. As the capital of the Tyrol, Innsbruck is the place of assemblage for its states and the seat of superior appeal, civil and criminal courts and of many important public offices. Many of the spots in the immediate vicinity have become memorable for the noble exploits which the Tyrolese peasantry performed in the War of Independene. Pop. 53,194, and mainly composed of German-speaking Roman Catholics.

INNUENDO, ĭn'ū-ĕn'dō, in law, an interpretation of words held to be injurious; specifically, in an action for libel or slander, an averment by the plaintiff that written or spoken words of the defendant, though apparently not actionable, are in reality defamatory. This clause is used in a declaration to explain the meaning of words only when they are ambiguous in meaning or application. If not justified by preceding averments, it may be rejected as superfluous. See LIBEL; SLANDER.

INNUITS, ĭn'ū-ĭts. See ESKIMOS.

INO, daughter of Cadmus and Harmonia, second wife of Athamas (q.v.), king of Bœotia, who drew upon herself the anger of Hera by nursing Dionysus, the son by Zeus of her sister Semele. In order to favor her own children she projected the murder of her stepchildren, Phryxus and Helle, who saved themselves by flight. Hera, still more highly incensed, made Athamas, the husband of Ino, mad, and he dashed Learchus, his eldest son by Ino, against a rock. Ino fled with her youngest son, Melicertes, and threw herself with him into the sea. Ino and Melicertes were made sea deities at the prayer of Dionysus. Ino was worshiped

under the name of Leucothea. There are a number of variations of this legend. It formed the basis of lost tragedies by Æschylus, Sophocles and Euripides, as well as by other Greek and Roman writers. Consult Gruppe, O., 'Griechische Mythologie und Religionsgeschichte' (2 vols., Munich 1906); Preller, L., 'Griechische Mythologie' (2 vols., 4th ed., 1887).

INOCARPUS, ī-nō-kär'pŭs, a genus of leguminous plants, having unifoliolate leaves and yellow flowers in axillary spikes. *I. edulis* is the South Sea chestnut, native of Tahiti. It is a large tree, with luxuriant foliage, the delicate evergreen leaves being six inches or more in length. It furnishes seeds or nuts much valued in the South Sea Islands, the inhabitants gathering them while green and mashing them for food.

INOCULATION. See Infection; Vaccination.

INOFFICIOUS TESTAMENT, a testament under which no provision is made by the testator for his issue and in which no reason is assigned for the omission. In nearly all jurisdictions such a testament is considered void. See Heir; Succession; Testament.

INOSIT ($C_6H_{12}O_6$), from Greek *is, inos,* a nerve, a muscle), a saccharine substance found in the muscular tissues of the heart, as well as liver, brain, kidneys, etc. It appears both in health and, to an abnormal amount, in disease. It exists also in a number of plants, such as foxglove, potato, kidney-bean, acacia, asparagus, cabbage. See Glucose.

INOUYE, ē'nō-oo'yā', **Kaoru,** Marquis, famous Japanese statesman: b. 1835; d. Tokio, 1 Sept. 1915. As a young man he was violently opposed to the intrusion of foreigners at the time when Japan first sanctioned the building of foreign legations in Tokio. Together with his friend Ito, afterward Prince Ito, he set fire to the newly-built British legation as a protest. A secret visit to England in 1864, however, completely changed the ideas of Inouye and Ito. It was forbidden then for Japanese to leave their country, hence visits to foreign lands had to be carried out surreptitiously. The enlarged views which Inouye and Ito took back home brought them into collision with their countrymen and led to a murderous attack on the former. The new ideas spread, however; the great clans of Satsuma, Tosa and Choshu rallied to the cause of national regeneration. Inouye was one of the most prominent leaders in the great reform movement that culminated with extraordinary rapidity in the revolution of 1867 and brought Japan at a bound from a condition of Oriental mediævalism into the front rank of nations. Bows and arrows were still used in the army. In 1870 Inouye became Vice-Minister of Finance in the Okuma administration, his first official appointment. Down to 1898, when he retired from public life, he had held the portfolios of Foreign Affairs, Home Affairs, Finance, Agriculture and Commerce. In every department he displayed resourcefulness, courage and energy, gaining a reputation as a great statesman and a builder of modern Japan. In 1894, after the Japanese had driven the Chinese out of Korea, Inouye was sent to Seoul to reorganize the Korean administration and to superintend the introduction of much-needed reforms. At the outbreak of the Russo-Japanese War Inouye, though in retirement, was commanded by the emperor to attend all important councils and to advise the Minister of Finance. He was created a count in 1884 and marquis in 1907. See Japan.

INOWRAZLAU, e'no-vrats'laf, Prussia, town of the province of Posen, 20 miles southwest of Thorn. It contains a gymnasium, Kurhaus and a mediæval church. Its industrial establishments comprise iron works, sugar refineries, flouring mills, brickyards, salt works, etc. It has also a large trade in the agricultural products of the district of which it is the centre. Pop. 26,141.

INQUEST, *in law,* a formal legal inquiry into special matters, as a death, lunacy, an undefended lawsuit or the like; also, the jury making such inquiry. The term had its origin in remote antiquity. It has been in use in England for various purposes for many centuries. It was used not only for official investigation into judicial matters but administrative matters as well.

One of its most important functions, today, both in American and in English law, is to investigate deaths under certain circumstances, as in prison, where violence is suspected, etc. The inquest is usually in charge of an officer known as the coroner, but sometimes it is conducted by a medical inspector, as in some jurisdictions in the United States. The evidence at inquests is taken under oath, after the jury has viewed the body. Often medical experts are called in and a post-mortem examination made of the body. If the verdict of the jury in attendance finds any person guilty of homicide, he is committed to prison to await trial. See Coroner.

Another function of the inquest is to determine whether the government is the lawful owner of lands or goods by forfeiture or lands by escheat. This proceeding is known as "inquest of office" or "office found." In the United States generally this proceeding is held by a commissioner, or similar official, under the direction usually of the Attorney-General. Still another function of the inquest is to determine, under the direction of the sheriff of a county and a jury, the amount of damages due from a defendant to a plaintiff in cases in which the defendant failed to appear or answer and judgment was by default. The procedure is also common in cases of garnishment, replevin and attachment to decide who is entitled to the property in dispute.

INQUILINE, in'kwī-līn, a term applied in zoology to animals which live as tenants within the nests or homes of other animals. The use of the term is almost entirely confined to entomology and then often restricted to the cases in which the rightful and the intruding tenants are closely related. Similar cases among other animals are commonly designated as commensalism (q.v.), but these and similar terms are used rather loosely. Examples of the inquiline relation occur among the termites, ants and bees, but are known especially among the gall-flies (*Cynipidæ*); indeed, one entire division, comprising more than 500 species, is named

Inquilinæ, because of the predominance of this mode of life. These insects differ but little in structure from the true gall-flies, but they lack the power to produce galls and consequently deposit their eggs within those of other species. They infest certain species of galls, as those of the blackberry and some oak-galls, in large numbers and sometimes more than one kind occur in a single gall. Perhaps the most remarkable feature of these inquilines is their frequent close resemblance to the insect which produces the gall which they infest.

INQUISITION, a tribunal or system of tribunals instituted by the Roman Catholic Church for the discovery, examination and conviction of heretics and their punishment by the secular arm. Under the successors of Constantine in the Roman Empire the repression of heresy, or rather the enforcement of the decrees of Church councils and synods, was a function of the imperial government, which inflicted temporal penalties upon the propagators of religious beliefs that contradicted the creeds approved by the state. When the reigning emperor was a favorer of Arianism or any other of the heterodox creeds, the orthodox bishops and their flocks were persecuted; when he was of the orthodox party the heterodox sects were put under the ban. In executing the decrees of the councils the imperial officials, called in the laws of Theodosius and Justinian "inquisitors" (*inquisitores*), were assisted by the bishops; but the tribunals were the ordinary secular courts, and judgment was rendered in the name of the state, not the Church. But in the 12th century, when the supremacy of the ecclesiastical power was universally recognized in western Europe, the initiative in the work of repressing heresy was taken by the Church as of course, and the discovery, trial and conviction of the offenders were functions of the ecclesiastical power solely: the secular power simply executed the judgments of the Church tribunals. Boniface VIII's definition of the respective powers and the mutual relations of Church and state was not proclaimed till the close of the 13th century; but had a similar definition been promulgated in the 12th century it would have expressed the universal sentiment of princes and peoples at the time. The celebrated bull, *Unam Sanctam,* defines that "Both swords, the spiritual and the temporal, are in the power of the Church; yet the one is to be wielded for the Church's behoof, but the other by the Church herself: the one by the hand of the priest, the other by that of the king and the soldier, though at the will and sufferance of the priest *ad nutum et patientiam sacerdotis.* And sword must be subordinate to sword—*oportet gladium esse sub gladio,* and the temporal authority subject to the spiritual power—*temporalem auctoritatem spirituali subjici potestati.*"

The first step toward the establishment of courts of inquisition would seem to have been taken in 1179 when the third Council of the Lateran issued a decree of excommunication against the adherents of the heretical sects of southern France, who are charged not only with holding abominable heretical tenets but also with practising "unheard-of cruelties against the Catholics," demolishing the churches and massacring widows and orphans. The Council grants "an indulgence of two years to those who shall make war on them." This decree was re-enforced by the Council of Verona (1184) over which Pope Lucius III presided and at which the Emperor Frederic I assisted; the Council directs the bishops to bring to trial persons accused of heresy and to inflict fit punishment on the guilty. The fourth Council of the Lateran (1215), held in the reign of Innocent III, imposed on the bishops the duty of making a visitation of their dioceses twice or at least once a year either personally or by delegates to see that the Church's laws be enforced. Bishops are authorized to bind the inhabitants of a district by oath to search out heretics and bring them to trial. By the Council of Toulouse (1229) in the pontificate of Gregory IX the search for heretics (*inquisitio hæreticæ pravitatis*) was systematized. The bishops are to name for each parish two or three respectable laymen who shall take oath zealously to search out heretics and to deliver them up to the *baillis.* Whosoever knowingly conceals a heretic loses all his goods. If heretics are discovered on the estate of a landowner, he incurs the penalties: the house of the heretic shall be torn down. Heretics who recant have to seek a new abode and must wear on their clothing two crosses of different colors until the Pope or his legate permits them to assume the ordinary garb. Whoever abstains from use of the sacraments is held suspect of heresy. A person convicted or suspected of heresy is debarred from the practice of medicine. Lest the ordinary Church authorities should be remiss in carrying out this system Gregory IX named (1232) as "pontifical inquisitors" monks or friars from outside, chiefly Dominicans; shortly after the pontifical inquisitors were chosen from the order of the Dominicans exclusively. Thus the duty of inquisition was taken out of the hands of the bishops and was discharged by officials, responsible only to the Pope; from the judgments of the inquisitorial tribunals there was no appeal but only to the Holy See: in 1263 Urban IV appointed an inquisitor-general for Provence, as a means of lowering the flood of appeals to Rome. The institution passed from southern France into the other provinces of that kingdom and into Italy, Germany and Poland. The Inquisition in England was directed by the metropolitans and their suffragans without being responsible to any inquisitor-general; but as long as Lollardism disturbed the peace of the Church the search for heretics was prosecuted rigorously: bishops and archdeacons were required twice a year to make inquisition of suspects: any man might be compelled under penalties to inform against persons suspected of heresy; the statute *de hæretico comburendo* was enacted by the Parliament in 1396.

In Spain the Inquisition, as set up in 1481 by Ferdinand and Isabella, was as much (or more) a political as an ecclesiastical institution: the officials from highest to lowest were appointed by the sovereigns and its action was directed by them without responsibility to the Holy See: Ranke calls the Spanish Inquisition "a royal tribunal furnished with spiritual weapons"; Llorente admits as much. The number of persons put to death under sentence of the Inquisition in Spain is put by Llorente at 31,000 from first to last, that is, during 330 years. But Llorente made it impossible to check his state-

ments by burning the original documents. Ranke impeaches his honesty; Prescott says that his estimates are "most improbable." Catholic historians call attention to the fact that not only heresy but many other offenses against the laws were judged by the courts of inquisition in Spain, viz.: polygamy, seduction, unnatural crimes, smuggling, witchcraft, sorcery, false personation, etc. At the time when the Inquisition flourished, persecution for heresy was a universal practice amongst all Christian peoples, and the methods of punishment inflicted were general throughout Europe. Protestant England persecuted as harshly and vigorously as Catholic Spain, and in both countries denial of the state religion was equivalent to treason.

INQUISITIVE WOMEN ('Le Donne Curiose'), an opera in three acts by Ermanno Wolf-Ferrari (libretto adapted by Luigi Sugana from a Goldoni comedy) first produced in Munich in 1903. The first dramatic work of the composer to secure more than local notice, this opera, or "musical comedy," as he terms it, quickly achieved world-wide success by reason of its vivacity and delicate charm. Of German and Italian parentage, Wolf-Ferrari is an eclectic. The artistic lineage of 'Le Donne Curiose' is plainly traceable to Mozart, though both 'Meistersinger' and 'Falstaff' influences are apparent. The orchestra, effectively used, is relatively a small one and in some respects the treatment harks back to an earlier day, when leading motives were less known. The music is distinguished by lyric simplicity and rythmical variety. The prevailing character is improvisational, well adapted to the slight tale of harmless intrigue which it accompanies. There are several easily recognized numbers — the trios in the first act, the quartet in the second, Rosaura's love soliloquy and the succeeding pages of almost Mozartean simplicity, the prelude to the last act, the barcarolle chorus and the final ensemble. There is no great emotional intensity, nor intellectual depth, but means and end are fitted in a thoroughly artistic and satisfying way.

Lewis M. Isaacs.

INSANE, Institutional Care of the, in the United States.— Previous to the 19th century there was practically speaking no such thing as care of the insane and no hospitals in which to care for them. The mentally ill were either permitted to roam at large, to subsist on begging and other charities, or indifferently confined with paupers in poorhouses or with criminals in prisons, or perhaps more frequently were cared for as best they could be by their people at home. This latter type of care was often not much better than the care that they received in prisons and in poorhouses because their folks were equally ignorant of how to minister to them.

Previous to the beginning of the 19th century there are recorded here and there laws addressed to the problem of the care of the insane. In 1676 a law of Massachusetts delegated the care of the person and the estate of the dependent insane to the selectmen. In 1798 a law was passed in the same State which provided for the commitment to the house of correction of lunatics who were "furiously mad." In 1811 the Massachusetts General Hospital was incorporated and the McLean Hospital established and subsequently opened in 1818. As early as 1650 in Rhode Island we find the Puritan, Roger Williams, making an urgent appeal on behalf of Mrs. Wilson, urging provision for her, whom he describes as a distracted woman. In 1725 a law was passed permitting inland towns to build houses of correction for vagrants and also for "mad persons." In 1742 the care of all the insane and imbeciles was given to the town council with power to appoint guardians for their estates. In 1828 the Dexter Hospital was opened and in 1847 the "Butler Asylum for the Insane." Similar records of legislation are found in a number of the other States, more particularly States along the Atlantic Coast. The earliest action in this country providing for the special care of the insane in specially constructed hospitals was taken by the "Religious Society of Friends" in 1709 and this action resulted in the foundation of the Pennsylvania Hospital in 1751. A portion of this hospital was set apart for the insane and the first patients were admitted in 1752. The first State hospital, however, for the exclusive care of the insane was established in Virginia and is now known as the Eastern State Hospital, at Williamsburg, Va. It was incorporated in 1768 under the name of the "Public Hospital for Persons of Insane and Disordered Minds" and its first patients were admitted in 1773. In 1806 an authorization to a hospital in the city of New York was granted to erect additions and provide suitable apartments for maniacs adapted to the various forms and degrees of insanity. Other important dates in the early part of the 19th century were the opening of an institution for the care of the insane at Frankfort, Pa., by the Society of Friends in 1817, the founding of the Hartford Retreat, in Hartford, Conn., in 1824, the opening of the South Carolina State Hospital for the Insane in 1824, of the Eastern State Hospital at Lexington, Ky., in 1824, of the Western State Hospital at Staunton, Va., in 1828, of one of the buildings of the Blockley Almshouse for the dependent insane in Philadelphia from 1830 to 1834, the Maryland State Hospital for the Insane in 1832, and the New Hampshire State Hospital for the Insane at Concord in 1842.

From this period on the erection of State hospitals went rapidly forward in the different States of the Union. The first law for the creation of a State hospital in New York was passed in 1842. The Utica State Hospital was opened approximately in 1850. The creation of this hospital, as of many others, was largely the work of Dorothea Lynde Dix (1802–87) whose broad philanthrophy extended over many States of the Union and in Europe as far as Constantinople. It was through her efforts that institutions were erected in Massachusetts, Pennsylvania, New Jersey, Rhode Island, North Carolina and the District of Columbia. Some 32 institutions in this country owe their existence, in whole or in part, according to her biographers, to her efforts.

These laws and the founding of these hospitals as above noted show the origin sporadically of those activities which were addressed toward the more humane and intelligent care of the insane. From the beginning of the 19th century on these activities became more numerous and the demands for better care gradually increased. For the most part, however, throughout the

first half of the century and during a considerable period of the latter half, the insane were cared for in a desultory and unintelligent way, largely by local communities, more especially in the various county houses throughout the States. This county house care of the insane placed them on a social par with the paupers, and it not infrequently became a matter of pride to see how cheaply the county could care for these unfortunates. Not only was this true, but the mentally sick patients in the almshouses received practically no medical attention whatever, except as they might be visited occasionally by the physician who was employed to look after the almshouse patients and who almost always was a practitioner in a nearby town and only spent a brief period at intervals at the almshouse or came out on emergencies when requested. He practically never had any experience or any special knowledge of mental illnesses and did little more than look after the physical condition of his patients, generally in a very crude way. The quarters where the mental cases were kept were usually presided over by persons who had no idea of the nature of their problems, were ignorant, often cruel and unsympathetic, so that the lot of these poor people was indeed miserable. They were practically prisoners shut out from all intercourse with their fellows, confined in quarters that were often filthy, dark, unsanitary and unhygienic in every particular, dominated by ignorant and not infrequently cruel caretakers, cheaply fed and clothed, with no medical supervision worthy of the name, and without any effort being made in any direction to bring about an improvement or to effect a cure. The most important move toward the latter part of the century which was made for the better and more humane, more intelligent and scientific care of the mentally ill, was the movement inaugurated in many of the States for State care, namely, provision by the State of public hospitals for the insane, with the consequent removal from the almshouses of this class of patients and transferring them to the State hospitals.

This was the only solution of the neglect and inefficiency of the county care system. The most fundamental defect of the county care system was that the county was too small a political unit to undertake the problem. It had not enough money to properly equip an institution nor did it have a sufficiently broad vision to secure the services of persons competent to handle the problem. All these matters were changed in the State hospitals. The State hospital was well built, well equipped and for the most part well officered, and the improvement in the care of the insane as a result was very great.

In the first period of State hospital care the main effort was to get away from the abuses of the county system and was directed toward humane and philanthropic efforts. The dealing with the mentally deranged patients as though they were sick and trying to effect a cure was as a matter of fact in the minds of the early hospital superintendents, but did not prevent them in many instances from making the mistake of creating enormous asylums for the so-called chronic insane and setting apart single institutions for the care and treatment of the acute cases, thus making out of the asylums places where all hope was lost for those who entered, and overcrowding and overworking the acute reception hospitals beyond their capacity. For many years, for example, the Utica State Hospital at Utica, N. Y., was reserved for the acute cases of the State, while other institutions, as they were built, were reserved for the chronic, incurable class. The next movement was to make out of all of the State institutions hospitals in the real sense of that word, places where the patients would be dealt with as actually ill and an effort made to cure them. The first efforts in this direction were crude, consisting largely in endeavors to treat the patients as patients were treated in general hospitals by keeping them in bed, making observations upon their general physical condition, taking their pulse, temperature, respirations, examining urine, the internal organs, etc., and treating the physical disease which might be found as a result of such examination. This movement did much toward getting better surroundings for the patients, it was contemporaneous with the establishment of training schools for nurses in the State institutions, and its general result was a vast improvement in the quality of care.

Throughout this latter period the hospitals had more or less actively been engaged in a study of the problems of mental disease with a view to discovering their scientific bearings. These researches led to the definite establishment in connection with well-organized State institutions of scientific departments, usually consisting of a laboratory for clinical pathology, and generally also a laboratory for research in pathology. In these laboratories the autopsy material was studied with a view to discovering the correlation between the mental symptoms of the patient and the changes that were found to have occurred in the brain.

Beginning with the latter portion of the 19th century the several States began to appreciate the great extent of the economic problem that was involved in the care and treatment of the insane in their large public hospitals, and there began to be a more or less consistently directed attitude of study of these problems together with a study of methods of administration and control which would look toward higher efficiency and greater economy. The result has been that in most of the States where there are several institutions for the care of the insane that these institutions are controlled by a central body, a lunacy commission or a board of control, usually appointed by the governor. Sometimes these boards of control have still larger powers and include all of the charitable institutions. The details differ in the different States, but central control is the thing aimed at. Along with this central control the scientific departments of the institutions increase in importance and in some instances, as in New York, Massachusetts, Illinois, there are central research departments for all of the hospitals.

The changes in the outlook for the care of the insane largely as a result of all this scientific work have been very great. Interest no longer centres in the autopsy room in attempts to correlate pathological findings and mental symptoms. The interest now is in the living patient and the scientific institutions have elaborated their departments of clinical pathology

for the purpose of studying the processes that are going on in the living patient, while psychological investigations, are becoming much more in vogue with the development of definite interests in psychotherapeutics.

The large housing problem which confronts the several States is still dealt with by the State hospitals, none of which are longer considered, however, as institutions for the chronic insane. All of the hospitals are equipped for taking care of all varieties of illness, mental and physical, acute and chronic. It is recognized, however, that in large centres of population there should be easy access to wards where mental illness could be intelligently handled. The result has been the creation of psychopathic wards or institutions in a number of cities: Albany, N. Y., Boston, Ann Arbor, Mich., Baltimore. These institutions care for the great stream of mental cases which come from large urban populations and which ordinarily would be distributed in other wards of the city hospital. For example, the alcoholic wards of Bellevue hospital are under the immediate charge of the psychiatrist in charge of the psychopathic pavilion. Thus are the problems of general medicine and psychiatry coming to be considered together and their respective specialists are coming to be of mutual assistance.

As mental disease has come to be considered more and more a matter of defective psychological adjustment and methods of psychotherapy have been more and more applied, the hospitals have reached out into the communities which they serve and through the intermediation of dispensaries and social workers have endeavored to extend aid to these communities and also endeavored to assist the discharged patients in rehabilitating themselves in the community. The State hospital, therefore, has come in the past hundred years from a condition in which it was merely a place to confine "mad" persons, to be a centre for education in matters pertaining to mental illness and for the rehabilitation of failures and defects in adjustment for the community in which it is located.

As outlined, the problem of the care of the insane has been gradually evolving as it became progressively larger, first a matter for villages and townships, and for counties, and finally a matter for individual State hospitals, receiving patients from a certain number of counties, then a matter for the State as a whole, governing its several State hospitals by a central board. Beyond that there has never been any recognized statutory central control. The superintendents of all of the institutions for the care of the insane have been organized into a medical society which has now been in existence since 1844, originally known as the Assocation of Medical Superintendents of American Institutions for the Insane. Since 1893 it has been known as the American Medico-Psychological Association. This association has through the years been the clearing-house to which annually was brought all institutional problems and has served most eminently in helping along the work of the care of the insane in several States of the Union. This until recently has been the only agency which in any way correlated the work of the several institutions throughout the country. In 1909, however, there was organized the National Committee for Mental Hygiene under the stimulus and as a result of the unceasing efforts of Mr. Clifford W. Beers. Mr. Beers had himself had a serious attack of mental illness in the course of which he had been a patient in more than one institution. As a result of his experience he felt convinced of the need of an organization which was independent either of political influence or financial or other personal consideration which would help various hospitals to deal with their problems to better advantage. As always happens in large problems the individual elements of which are dispersed over a wide territory, many of the institutions and some of the States remained very backward in their care of the insane. There were no members in their hospitals of the central organization, The American Medico-Psychological Association. As some of the State institutions were as badly off as had been the county asylums, it became the function of the National Committee to endeavor to improve these bad spots throughout the country and in doing so it took an attitude of helpfulness rather than one of criticism and as a result almost always found that defects in methods were due to ignorance, many primitively conducted institutions really believing that they were giving the best possible service that medical science could suggest. Such institutions were quick to avail themselves of the help of the National Committee and a great deal of improvement throughout the country has resulted from its activities. This has been the work of the National Committee until the beginning of the European War, when it turned its attention practically entirely to war work. The great importance, however, which the conduct of this war of necessity attached to mental problems will result in great benefit to this particular department of medicine.

WILLIAM A. WHITE,
Superintendent Saint Elizabeths Hospital, Washington, D. C.

INSANE, Statistics of. Statistical data relating to the insane in the United States are found principally in Federal census reports, the reports of State commissions charged with the supervision of the insane, reports of individual State hospitals and special studies. In 1904 and in 1910 the United States Census Bureau issued a special statistical volume relating to the insane and feeble-minded. Prior to 1904 the data concerning the insane were made a part of the general decennial census report. Beginning with 1850 and continuing to 1890 an attempt was made at each decennial census of the population to secure a complete enumeration of the insane by inserting a question relative to insanity in the general population schedule. The results down to 1880 were unsatisfactory as it is generally believed that only a small portion of the people suffering from mental disorders were enumerated as insane. At the tenth census, 1880, the returns of the enumerators were supplemented by special reports from physicians. The latter reported about 17 per cent of the total number of insane enumerated in that year. In taking the census of 1890 no attempt was made to secure supplemental data from physicians. Consequently, the number of insane enumerated in that year did not show an increase commensurate with the growth of the population. In the census of 1900 and of 1910 the question relating to the insane was omitted from the general population schedule. In 1904 a census of the insane in institutions was taken by special enumerators appointed for such purpose. A similar census was taken again in 1910. In 1917 the National Committee for Mental Hygiene made a special census of the insane in institutions, the data being obtained from schedules filled out by hospital superintendents.

These various enumerations of the insane, while in part incomplete, give a general view of the increase in insanity in the United States since 1850. The following tabulation shows the total insane enumerated at each of the several censuses, together with the number of insane per 100,000 of the population:

YEAR OF CENSUS	Total insane enumerated: Number	Total insane enumerated: Per 100,000 population
1917*	234,055	227.6
1910*	187,791	204.2
1904*	150,151	183.6
1890	106,485	170.0
1880	91,959	183.3
1870†	37,432	97.1
1860†	24,042	76.5
1850†	15,610	67.3

* No enumeration of insane outside of institutions.
† Enumeration believed to have been seriously deficient.

The data for the years 1904, 1910 and 1917, which relate to the insane in institutions only, show a remarkable increase of this class of unfortunates as compared with the increase of the general population. The ratio of the insane in institutions to the general population in 1904 was 1 to 545, in 1910, 1 to 490 and in 1917, 1 to 439. It is probable that the actual increase in insanity has not been as great as these figures would indicate. During the last 15 years the practice of placing the insane under institutional care has been greatly extended. As the institutions for the care of the insane have improved they have won a greater degree of public favor, and more mild cases of mental disorder have been admitted thereto. As the incidence of mental disorder increases with advancing age, the lengthening of the average period of human life in recent years has increased the insanity rate by bringing a larger proportion of the population into the advanced age periods. The rate of insanity is found to be much higher in cities than in rural districts. The trend of the population from country to city during the last three decades have therefore been an important factor in causing the upward trend of the rate. After all allowances have been made, however, it is believed by those who have given careful attention to the subject that the insane are increasing more rapidly than the general population, but that the difference in rate of increase is too slight to be alarming.

Insanity in the Several States.— Owing to various factors, such as institutional provision for the insane, distribution of urban and rural population, the composition of the population with respect to age, nativity and race, marked differences in the ratio of the insane to the general population are found in the various States. The following table shows the insane in institutions in the United States by divisions and States in 1910 and 1917, together with the number per 100,000 of general population in each of the two years:

INSANE IN INSTITUTIONS IN THE UNITED STATES BY DIVISIONS AND STATES 1 JAN. 1910 AND 1 JAN. 1917.

DIVISIONS AND STATES	Number: 1 Jan. 1910	Number: 1 Jan. 1917	Rate per 100,000 of general population: 1 Jan. 1910	Rate per 100,000 of general population: 1 Jan. 1917

Oregon	1,565	2,309	232.6	272.0
California	6,652	9,698	279.8	325.0

Insane in Foreign Countries.— Available statistics of the insane in foreign countries are very unsatisfactory. The classifications of mental disorders in the various nationalities are dissimilar and wide variations exist in the provision made for the care of the mentally afflicted. In some cases the insane are enumerated with the feeble-minded and epileptic and the number of the separate classes is not given.

On account of shell shock and the stresses of army life, it is believed that insanity has greatly increased in the belligerent countries of Europe since the beginning of the present war, but the conversion of hospitals for the

insane into military hospitals has reduced the number of civil insane in institutions in these countries. Current statistics of the civil insane in the European countries at war are therefore misleading.

According to the report of the Commissioners in Lunacy, published in 1914, the insane in England and Wales increased from 36,762 in 1859 to 140,237 in 1914, an increase of 281.5 per cent. During the same period the general population of these countries increased 89.5 per cent. The ratio of insane to the general population in England and Wales on 1 Jan. 1914 was 1 to 266, or 376 per 100,000. During the year 1913 there were 18,407 first admissions and 3,896 readmissions to institutions, for the insane in these countries. The rate of first admissions during 1913 was 49.9 per 100,000.

The report of the Inspectors of Lunatics for Ireland for the year ending 31 Dec. 1915 gives the number of insane in institutions in Ireland on 1 Jan. 1915 as 25,180, or a ratio of 575 per 100,000 of estimated population. The number of first admissions in 1914 was 2,798, a ratio of 64 per 100,000 of estimated population. The readmissions numbered 730.

In Scotland, on 1 Jan. 1914, there were 18,682 insane patients in institutions, a ratio of 394 per 100,000. The admissions in 1913 numbered 2,908, a ratio of 61.4 per 100,000 of estimated population.

In Australia, on 1 Jan. 1913, there were 16,439 insane persons under care, a ratio of 347 per 100,000 of estimated population.

In the Netherlands, on 1 Jan. 1914, there were 13,975 insane persons in institutions. The admissions during the preceding year numbered 2,897.

The following table gives a comparison of the increase of insane patients under treatment in various countries from 1890 to 1910, together with the ratio of the insane to the general population in 1910. Owing to the reasons above stated the ratios must be taken with some allowance.

COMPARISON OF INCREASE OF INSANE PATIENTS UNDER TREATMENT IN VARIOUS COUNTRIES, 1890–1910.

(Compiled from official yearbooks and census reports).

COUNTRIES	Insane in institutions 1 Jan. 1890	1 Jan. 1900	1 Jan. 1910	Number per 100,000 of population in 1910

* 1904. ** Data not available. † 1892. ‡ 1902. § 1908

Switzerland on 1 Jan. 1916 was caring for 9,916 insane patients in its 24 hospitals. The admissions of the preceding year totaled 4,070.

In Sweden, in 1914, the 18 hospitals for the insane housed an average patient population of 9,610. In 1910 the average number housed was 7,866. There were 1,978 admissions in 1910.

In Denmark, on 31 Dec. 1916, the insane in institutions numbered 4,644, a ratio of 168 per 100,000 of the general population.

The insane in public and private institutions in Germany increased from 78,155 in 1891 to 120,872 in 1901. Since 1901, the data in the German yearbooks concerning the insane have included feeble-minded, epileptics, etc.

The total population of the hospitals for the insane in France on 31 Dec. 1912 was 77,237.

Sex of Insane.— The total number of insane enumerated in institutions in the United States on 1 Jan. 1910, included 98,695 males and 89,096 females; the total number of insane admitted during the year 1910 included 34,116 males and 26,653 females. The rates per 100,000 of the general population were: Males, 72.1; females, 59.7; total, 66.1. The ratio of males to females among patients in institutions was 110.8 to 100; and among admissions, 128 to 100. In the general population of the United States in 1910 the ratio of males to females was 106 to 100.

In New York State where the sexes are nearly equally distributed in the general population, on 30 June 1917, there were 18,422 males and 20,342 females in institutions for the insane, a ratio of 90.6 males to 100 females. Among the first admissions to all institutions for the insane in the State in 1917, there were 3,878 males and 3,462 females, a ratio of 112 males to 100 females.

The excess of males among first admissions is largely due to the greater prevalence of general paralysis and alcoholic insanity in this sex. As patients with general paralysis have a high rate of mortality and patients with alcoholic insanity improve rapidly, the average duration of hospital life is less for males than for females. In the New York civil State hospitals in 1917 the average duration of the hospital life of the male patients who died in the hospitals was 5.5 years, and of the female, 7.2 years.

Age of the Insane.— Mental diseases occur principally during the period of adult life, the rate of incidence increasing with advancing age. The age distribution of the 6,877 first admissions to the New York civil State hospitals in 1917 as compared with the age distribution of the general population of the State in 1910 is given in the following table:

COMPARISON OF AGE DISTRIBUTION OF FIRST ADMISSIONS, 1917, AND OF THE GENERAL POPULATION OF THE STATE, 1910.

AGE	First admissions 1917	Per cent of total first admissions 1917	Per cent of general population of New York 1910
Under 15 years	12	0.2	27.3
15 to 19 years	317	4.6	9.2
20 to 24 years	721	10.5	10.3
25 to 29 years	833	12.1	9.7
30 to 34 years	835	12.1	8.4
35 to 39 years	797	11.6	7.8
40 to 44 years	639	9.3	6.6
45 to 49 years	604	8.8	5.5
50 to 54 years	518	7.5	4.6
55 to 59 years	405	5.9	3.2

Causes of Insanity.— Causes of mental diseases are multiple rather than single. Several factors may operate together to cause the onset of a psychosis. Alcohol has always been a prominent factor in the causation of mental disease but its influence seems to have declined in recent years. Syphilis is the primary cause in all cases of general paralysis and of psychoses with cerebral syphilis. Opium and its derivatives, cocaine and other habit-forming drugs cause psychoses in comparatively few cases. Arteriosclerosis by shutting off the blood supply to important parts of the brain prevents this organ from performing its natural functions and thus causes various forms of mental disorder. Blows on the head cause insanity in a similar way by injuring brain tissues. Fevers and exhausting physical diseases often give rise to mental disease.

Insanity may also be due to mental causes, such as fear, joy, anger, grief or anxiety.

Abnormal mental make-up in either the temperamental or intellectual sphere is a predisposing cause in many cases. The abnormal mind gives way to unusual stress while the normal mind is able to withstand it. When the stress is prolonged or of extraordinary severity, as in army life, even the normal mind may give way.

The following table shows the relative prominence of the principal definite causes among males and females as reported by the New York State hospitals.

CAUSES OF MENTAL DISEASE AMONG FIRST ADMISSIONS TO THE CIVIL NEW YORK STATE HOSPITALS FOR THE INSANE, FOR THE YEAR ENDING 30 JUNE 1917.

CAUSES	Number of Cases Males	Females	Total	Per cent Males	Females	Total
Alcohol	655	209	864	18.2	6.4	12.6
Syphilis	750	212	962	20.8	6.5	14.0
Drugs	5	12	17	0.1	0.4	0.2

Total first admissions	3,605	3,272	*6,877	.....	.....	.....

* As each cause reported was enumerated, the number of causes exceeds the number of patients.

Insane Classified with Reference to Psychoses.— No nation-wide census of the insane in the United States with reference to psychoses of mental diseases has ever been taken. The accompanying table gives the result of a census of the 36,357 patients in the New York State hospitals taken by psychoses on 1 July 1917. As the patients of the New York State hospitals have been carefully classified with reference to psychoses for the past 10 years this census may be considered representative of the distribution of insane patients in institutions in the various clinical groups. As the duration of hospital life of patients in some groups is much longer than in others the distribution of the patients in the hospitals with respect to psychoses varies considerably from that of the newly-admitted cases. This is shown clearly in the accompanying table.

DISTRIBUTION BY PSYCHOSES OF INSANE PATIENTS IN CIVIL STATE HOSPITALS IN NEW YORK STATE AND OF FIRST ADMISSIONS TO SUCH HOSPITALS IN 1917.

PSYCHOSES	Patients in civil State hospitals, 30 June 1917 Number	Per cent	First admissions year ending 30 June 1917 Number	Per cent
Traumatic	53	0.15	18	0.3
Senile	1,238	3.41	585	8.5

Movement for Uniform Statistics of the Insane.— As previously pointed out, statistics of the insane until recent years dealt principally with the number enumerated in various States and countries without regard to the kinds of mental disease with which they were afflicted. In fact, the absence of a generally accepted classification prior to 1917 prevented the collection of national statistics of mental diseases. The first bureau of statistics for the study of mental diseases was established in 1908 by the New York State Commission in Lunacy (now the State Hospital Commission). The Commission adopted a uniform classification of mental diseases for use in its 13 State hospitals, and required the medical officers of each hospital to submit to the Commission's statistician a statistical card report concerning each case admitted, readmitted, discharged or deceased. From such cards yearly statistical reports have been prepared and published, and

the cards have been filed according to identification number and psychosis. The Commission now (1918) has a file of uniform cards of about 60,000 first admissions — the largest collection of systematic data concerning mental diseases in the world. By combining the cards received from all the hospitals for a series of years, the bureau is able to make intensive studies of the separate mental diseases.

The success of New York's pioneer work led the American Medico-Psychological Association to undertake a movement for uniform statistics of the insane throughout the United States. At the meeting of the Association held in Niagara Falls in June 1913, a special committee was appointed to devise ways and means of securing uniform statistical reports from institutions for the insane. This committee, after prolonged conferences, submitted its final report to the Association at the annual meeting held in New York in May 1917. The report recommended the adoption of a new classification of mental diseases and submitted outlines of 18 statistical tables for use in the annual reports of institutions for the insane. The committee stated that "the lack of uniformity in hospital reports at the present time makes it absolutely impossible to collect comparative statistics concerning mental diseases in different states and countries, and extremely difficult to secure comparative data relative to the movement of patients, administration and cost of maintenance and additions"; and that the "importance and need of such uniform data have been repeatedly emphasized by officers of the association, by statisticians of the United States Census Bureau, by editors of psychiatric journals and by administrative officers in various states." "Such data," the committee adds, "should serve as the basis for constructive work in raising the standard of care of the insane, as a guide for preventive effort, and as an aid in the progress of psychiatry." The report of the committee was unanimously adopted and a standing committee on statistics was appointed to secure the adoption of the new classification and statistical system by Federal and State authorities. In February 1918, such standing committee affiliated with the National Committee for Mental Hygiene which had received a special gift for statistical work.

Through the co-operative work of the two organizations a uniform system of statistics of mental diseases was put into operation in nearly all the State hospitals for the insane in the United States during the summer of 1918. The surgeon-general of the army, in September 1917, adopted practically the same system for use in the Division of Neurology and Psychiatry.

The Association's classification of mental diseases which forms the basis of the new statistical system consists of 22 groups of principal psychoses, some of which are subdivided into more or less distinct types. The classification is not regarded as final, but it constitutes the first successful attempt to secure uniformity in the designation of mental diseases in the United States.

Bibliography.— Census reports, Insane and Feeble-minded in Institutions, 1904 and 1910; 'Insane, Feebleminded, Epileptics and Inebriates in Institutions in the United States, Jan. 1, 1917,' by Horatio M. Pollock, Ph.D., and Miss Edith M. Furbush, A.B., B.S.; New York State Hospital Commission Reports 1908 to 1917; Report of Committee on Statistics of the American Medico-Psychological Association, 1917; Statistical Manual for use in Institutions for the Insane, published by the Bureau of Statistics of the National Committee for Mental Hygiene, 1918; Statistical yearbooks of forcign countries.

HORATIO M. POLLOCK.

INSANE ASYLUMS, Cottage System or Village Plan. A form of construction for insane asylums and charitable institutions, in which large buildings are replaced by detached cottages. The cottages vary in size from those which will accommodate six to a dozen patients to larger ones which will accommodate 20 or more. They are usually constructed either in groups or along streets and avenues as a village. In the former, the several groups are given up to a particular industry as a farm group, where the patients are employed at farming, and others, as the garden, the brick yard, shop industries, etc., all of these being a part of one institution on a single large estate. In the village plan the institution is laid off in streets and avenues, and has the appearance of an ordinary village, each cottage having a flower garden in front, shade trees,, etc. In either plan, there is conveniently located near the centre of the plant an administration building, a hospital for the sick and those requiring special care, a bakery, a laundry and other utility buildings. The cottages may be constructed of wood or other material, and the cost of construction is small as compared with the old plan of asylum construction. It is, besides, more homelike, more convenient for administration and permits of indefinite expansion. Some of the best-known institutions constructed on this plan are Alt-Scherbitz near Leipzig; Gabersee near Munich, Germany; the Saint Lawrence State Hospital at Ogdensburg, N. Y., and the Craig Colony for Epileptics at Sonyea, N. Y.

INSANITY. This is a purely legal term. Its use as a medical term should cease as it leads to interminable confusion and defeats the ends of justice. The confusion is very old however and will take time to eradicate. Insanity then simply represents certain legal situations which by reason of one or another disease, chiefly involving the brain, render the individual responsible or not responsible for a criminal act, an act of contract making or of making a will. If, according to the evidence adduced before a properly constituted legal tribunal, it is decided that the individual's acts in question were not responsible, or he did not have contract capacity, or he did not possess testamentary capacity, because of some disease, injury or defect of the brain, then the individual in question has thrust upon him a legal status — insane. It is necessary to insist upon the purely legal character of the situation — because the tests for responsibility for contract capacity, for testamentary capacity vary with every jurisdiction. Thus a man may be insane in New York and sane in New Jersey, or vice-versa. He only has to step over the line. Certainly this is not a medical concept of a disease. No disease can change by crossing a territorial line. Thus it must come about that the word insane — insanity, etc., must be confined purely to its legal usage — or better abolished entirely.

The confusion arose in the days of the Roman law, and law is such a conservative instrument it is hard to eradicate old conceptions. In Roman days all brain diseases were lumped into one. The Romans despised Greek subtleties, they said, just as most stupid people despise their superiors in intelligence. The Greeks had separated various brain diseases and gave them different names. They were really a scientific people. But the Romans had a passion for organization. They lumped all of these very diverse diseases and called them "*Insania.*" To them insania was *a* brain disease. What are really different brain diseases, they called "forms of insanity." This is a false and nonsensical concept and leads to much mischief in our present law court practice. Thus in New York State the legal test for responsibility is whether the individual knows the nature and quality of an act and knows whether it is wrong. There are a number of very severe and chronic mental illnesses which totally destroy an individual's responsibility, but such individuals may still retain this purely intellectual test. New York State would electrocute such seriously sick individuals and commit an act of gross injustice. In New Jersey — another feature is added to this test — namely, the capacity to resist an impulse, and in other States other tests. The whole test business is largely a farce, and is founded on the totally erroneous idea in the minds of law givers that there is such a disease as "insanity" and that it has different "forms." There is no such thing as a disease "insanity" — and there are no forms of it, just as there is no disease called "cough." One may cough from dust, from gas, from tuberculosis, from bronchitis, from cancer of the larynx, to warn a friend or to hide a confusion. Certainly dust, gas, tuberculosis, bronchitis, cancer, warning and hiding are not *a* disease. So an individual may have a brain tumor, he may have a meningitis, a syphilis of the brain, tuberculosis of the brain, thyroid poisoning, a paranoia, a dementia precox or any of a hundred different and dissimilar diseases, and as a result of such a disease he may commit an antisocial act, which if resulting from the disease caused him not to know the nature and the quality of the act, not know it was wrong, or knowing these things even, may have believed himself commanded by God to do the deed, then, varying with the State's legal definition, he becomes legally insane. He acquires a purely legal status. He has not got any insanity. There is no such disease. He may have one of the diseases just enumerated, which causes him to acquire a legal status. See PSYCHIATRY; MENTAL DISEASES.

INSANITY, in the legal sense, such a degree of mental unsoundness as to call for the restraint of the person afflicted or to justify the authorities in depriving him of the management of his property and affairs. An insane person comes in contact with the law (1) when he suffers from such unsoundness of mind that it is necessary for his own or the public welfare that his liberty be restricted; (2) when he is incapable of managing himself or his affairs, or of directing their management; and (3) when a plea of insanity is entered on his behalf in answer to a criminal charge. Insanity in a legal sense includes only questions of life or property, competency and responsibility, and ability to transact the affairs of life. According to the law of the United States, the modern view is that whether a person is or is not insane is in every case a question of fact. The courts are quite liberal in attempting to sustain wills of persons who are not wholly insane. If a person has sufficient understanding to comprehend the nature of the testamentary act, knows the nature of his property and shows clearly that he could decide why he wanted his property to go to the beneficiaries named, his will is usually received and probated. An insane person is responsible for his torts. He is criminally responsible for his actions, unless from defective mental power or from mental disease he cannot understand the nature of his acts, or does not know that his act is wrong, or is unable to control his conduct — unless, in the last case, his want of control arises from his own fault. An insane person must sue or defend an action through his guardian *ad litem.* A person confined against his will as insane is entitled to a writ of *habeas corpus* and a judicial inquiry as to the legality of his detention.

INSCRIPTIONS. The term inscriptions comprises, in its widest sense, all words or word-signs engraved (or painted) on relatively durable materials such as natural cliffs, wrought stone, baked clay, metal or even wood. For reasons of practical convenience, however, certain sorts of inscriptions are grouped apart; for example, legends on coins and the lettering on painted vases. The etymological sense of inscription (Latin *inscriptio,* "in-scratching") is not to be taken so strictly as to exclude raised lettering. The rôle of inscriptions in modern times accords in general with the ancient use, but is much less extended. Then, copies of official and religious documents were frequently promulgated in the form of inscriptions, a usage that no longer survives, though commemorative and titular inscriptions are still plentifully employed. In general, inscriptions serve one of two purposes: (1) they constitute a record, and the material containing them is wrought for the express purpose of receiving the inscription (example, known from literature only, Moses' stones tables that held the decalogue); (2) the object on which the inscription is engraved fulfils a purpose of its own, while the lettering indicates the name, nature, purpose, maker or owner of the material object (commemorative column, mirror, ring, etc.). To these may be added another class, (3) the incidental inscription, a notice or entry upon an object not prepared to receive it.

Inscriptions furnish materials of value to students in many fields. To the historian — and we must understand history to be the life-record of the nation and its citizens — they supply evidence of great value, all the more valuable because nearly always contemporaneous with the facts recorded. The incidental as well as the formal record may bear testimony. An example of this sort has been found on the leg of a colossal statue at Abusimbel in Nubia, whereon Greek mercenaries who had ascended the Nile under the leadership of Psammetichus — more probably the second (594–589 B.C.) than the first (654–617) of that name — traced a brief notice of their expedition. The

incidental inscription is particularly apt to furnish details valuable for social history. To the archæologist inscriptions of the second class furnish testimony of value for topography (witness the fragments of the marble *Forma Urbis*, an ancient inscribed plan of the chief buildings of Rome) and for the precise identification of statues and other works of art. The discovery of inscriptions is among the express tasks of the excavating archæologist, who thus supplies the raw material, so to speak, for the historian or philologian. To the philologian inscriptions yield the key to the history of writing and, if his interests lie in the comparative and historical study of words, give him a fuller knowledge of their form. To the philologian of literary interests, inscriptions yield a knowledge of historical fact or of vocabulary that may lead to a correct interpretation of a difficult literary passage. For example, the Greek historian, Thucydides, records (6.54) an altar inscription set up by Peisistratus (527–510 B.C.), which, he says, was still "in clear evidence," but "in dim letters." The identical inscription was found in 1877, with lettering perfectly distinct, and the literary interpretation of "dim" had to be revised and brought into accord with the facts. Meantime, the archæologists had learned that red or blue paint was employed to bring out more clearly the lettering of Greek inscriptions, and it was easy to infer that not the incision but the coloring of this inscription was dim in the time of Thucydides. Inscriptions previously known from literary works have for the philologian the added value of yielding testimony concerning the reliability of the manuscript tradition. Thus the best manuscript of Thucydides is of the 10th century A.D. and, as the last in a long chain of copies, must have been exposed to a great deal of corruption in transmission. The fact that a treaty recorded by the historian (5.47) corresponds almost exactly with the (fragmentary) inscription recording the alliance is reassuring for the MS. tradition. The *littérateur*, even, may be concerned with material furnished by inscriptions. One of the most considerable fragments of the poet Simonides, for example, has reached us in a copy on stone of an epitaph (epigram) in honor of the Megarians who fell in the Persian War. Some literatures have survived only as inscriptions.

It is safe to declare that inscriptions are as widely diffused as the art of writing. Even a primitive picture, if painted to convey a message, would constitute an inscription. Hieroglyphics (conventionalized picture writing) constitute the most primitive type of writing, and inscriptions of this sort, in the Maya language, are found in Yucatan. Though probably not earlier than the discovery of America, these represent, as regards writing, the same stage of culture as the hieroglyphics of Egypt (4700 B.C.). Chinese inscriptions — the Chinese being a highly conventionalized hieroglyphic script — of 1200 B.C. are also extant. The Mayan (and Aztec) system is still very imperfectly understood. Egyptian hieroglyphics were likewise long undeciphered, but in 1822 the Rosetta Stone (q.v.), a trilingual in Greek, demotic Egyptian, and hieroglyphics whereon the names Ptolemy and Cleopatra were of frequent occurrence, furnished a clue to the hieroglyphics which had been conventionalized, through a syllabary, to a pure phonetic system. —— This means, to invent an instance, that a picture (symbol) representing motion [= (to) go] comes to be used for the syllable *go* in a proper name like Goshen (this step was taken by Aztec hieroglyphics), or in a word like gopher: and that in the last stage the syllable sign *go* reduces to the letter *g*. — — The decipherment and interpretation of Egyptian inscription belongs to the science called Egyptology. See EGYPT.

The cuneiform script, invented by the Accadians of Chaldæa, found its way to the Semites of Babylonia and Assyria. This was a syllabary, developed from an earlier pictorial system, and such it remained in those countries, where not only small objects like seals and cylinders, but whole libraries of clay tablets (reaching back into the 4th millennium B.C.), have been found. These tablets contain genuine literary works as well as the documents and announcements commonly included under the term inscriptions. The University of Pennsylvania is in possession of some 35,000 cuneiform documents, a collection particularly rich in fourth and second millennium records, and outnumbered only by the British Museum and the Louvre collections. The Tell-el-Amarna Letters are historically among the most noteworthy cuneiform inscriptions. Found by an Egyptian peasant woman in 1887, the collection is now split up between the Berlin and British museums, though a part remains in Egypt. These tablets contain a correspondence between three kings of Egypt (15th century B.C.) and the rulers of Babylonia, Assyria, Armenia, the states of Asia Minor, Syria and Palestine. Of transcendent importance for the early political history of western Asia, this correspondence is also accounted to confirm the validity of the Hebrew Scriptures as an historical record. It is noteworthy for the history of culture that the petty chief of every town could command the services of a scribe able to write a letter in Assyrian — the common correspondence language, it would seem, of all those countries. The science of Semitic Cuneiform belongs to Assyriology (q.v.).

Fortunately the Assyrian syllabary, after being borrowed by the Medic Aryans, was converted into an alphabetic system. King Darius (521 B.C.) caused an Old Persian (Protomedic) inscription of 413 lines, averaging 6 feet each, with versions in Neo-babylonian and Neo-elamitic, to be inscribed on the Great Rock of Behistun, at a height of 400–500 feet. The same script had been observed on another short inscription found at Persepolis, which evidently contained proper names chiefly. As early as 1802 Grotefend allocated the names Darius, Xerxes and Hystaspes to certain script groups in these brief formulæ, and correctly isolated nine of the 13 symbols concerned. In course of time the entire Protomedic cuneiform alphabet was identified and subsequently the more complex Semitic syllabaries were worked out, resulting in the decipherment of the older cuneiform. In the Behistun inscription Darius, following precedents of Assyrian kings, summed up the history of his accession and reign. Copied in 1844 by Mr. H. C. Rawlinson, it has been carefully inspected again (1903) by the American scholar, Mr. A. V. W. Jackson.

Farther west, the Phœnicians, also Semitic, developed, perhaps from Egyptian hieroglyphics, a true alphabet, out of which sprang, on the one hand, the scripts used by the Hebrews, Arabs, Persians and Hindus, and on the other the Greek (and Roman) type. The most notable early inscription in alphabetic Semitic is the Moabite Stone (q.v.) (9th century B.C.), which recounts the victory of Mesha, king of Moab, over Israel. The language used differs but slightly from that of the Hebrew Scriptures, of the historical validity of which the Moabite Stone, like the Tell-el-Amarna Letters, is held to be in general confirmatory. [For facsimile, transcript and translation consult Hastings' 'Dictionary of the Bible' (III, p. 405 seq.)]. Phœnician-Greek bilinguals from Cyprus, belonging to the 4th century B.C., are extant; also Phœnician-Cypriote, which furnished the key to the Cypriote syllabary. Punic inscriptions proper are chiefly of the dedicatory sort, and relatively late, all after the Greek period. Aramaic dockets on Assyrian contract tablets (8th century B.C.) form another instance of early alphabetic Semitic.

India also has its inscriptions. The oldest (250 B.C.) and most interesting are the religious edicts of King Piyadassi, known as the Asoka Edicts, which are engraved on rocks and pillars. They inculcate the religion and morals adopted by this king after his conversion to Buddhism. These inscriptions, in two unknown alphabets (Karosthī and Brahmī), were deciphered chiefly by James Prinsep, who, in the winter of 1837–38, single-handed, unraveled the Brahmī script. He guessed that in certain brief Brahmī inscriptions, plainly of a votive character, a frequently recurring final group of letters must stand for the notion "gift" and be equivalent, if the language was Sanskritic, to *dānam*. He further surmised that the consonant preceding *dānam* must be the genitive (possessive) sign — *s*. He thus isolated the three consonants *s, d, n*, and, with this start, soon identified the entire alphabet.

Greek and Roman inscriptions have been more studied and are accordingly more systematized for study than any others. The ancient Greeks were themselves conscious of the importance of inscriptions. Herodotus used them as sources, and Thucydides and Xenophon quoted them. Decrees are sparingly mentioned by Isocrates, but freely quoted by Demosthenes, who probably made use of the papyrus originals from the department of archives, not all decrees being promulgated on stone. Euripides alludes to the custom of inscribing formal compacts on tripods and dedicating them in temples. Greek antiquaries and scholars even made collections of inscriptions and Polemon (300 B.C.), who was neither the first nor the last of these collectors, owing to his zeal as an inscription hunter, got the nickname of *stèlokopas*, "tablet-picker." Roman writers also — Cicero, Livy, Pliny the Elder, Suetonius — occasionally mentioned inscriptions of historical interest. Varro, the antiquary, and the lexicographer, Verrius Flaccus, commented on the diction of inscriptions; while Polybius, the Greek historian of Rome, actually cited inscriptions, making a fuller use of them than Livy. But no interest in collecting inscriptions, comparable to the Greek interest, ever developed among the Romans. From the Revival of Learning on, scholars were not lacking to show an interest in classical inscriptions, but the modern impulse may be said to have had its point of departure in the first quarter of the 19th century when the Prussian Academy, under the promptings of August Boeckh, inaugurated the great collection known as the 'Corpus Inscriptionum Græcarum' (4 vols., 1825–56), which contained nearly 10,000 numbers. But fresh inscriptions are ever coming to light — *dies diem docet* — and in 1891 the number was estimated at 50,000. There has been a steady increase ever since. Excavations are now pursued in Greece and Grecian countries with a diligence and at an outlay never before known. Almost all the great nations have established archæological institutes in Athens, and all of these issue some form of learned journal devoted in part to the publication of the new inscriptions discovered; for example, 'Papers of the American School of Classical Studies at Athens,' *American Journal of Archæology, Bulletin de Correspondence Hellenique, Ephemeris Archaiologikè, Journal of Hellenic Studies, Mittheilungen des deutschen Archæologischen Institut, Archæologisch-Epigraphische Mittheilungen aus Oesterreich*, etc. Further great collections like Boeckh's have been issued, for example, the 'Corpus Inscriptionum Atticarum' and the 'Sammlung Dialekt-Inschriften' (in progress). A similar activity has been exhibited at Rome also, with the same establishment of archæological institutes. In 1863 the first volume of the 'Corpus Inscriptionun Latinarium,' also supported by the Prussian Academy, was issued. Since then 15 volumes, with numerous supplements, have been published, new inscriptions being first provisionally printed in the 'Ephemeris Epigraphica.' In all, some 150,000 Latin inscriptions are now accessible in print.

Classical inscriptions require two classes of investigator, the field collector and the closet student. A knowledge of Greek and Latin acquired from printed books does not equip the student for field collecting. It is true that the decipherment of the known script of classical inscriptions does not present problems like those solved by the ingenuity of Grotefend and Prinsep but, for all that, training is needed for the accurate reading and copying of the inscription. Absolute accuracy in copying is difficult of attainment, but a "squeeze" made of (unsized) paper, wetted and packed into every crevice, or a copy made by covering the inscription with a sheet of dry paper and rubbing the same with powdered graphite secure excellent results. America has produced one collector of large and successful experience, Mr. J. R. Sitlington Sterrett, whose collections are to be found chiefly in the 'Papers of the American School.' After correct copies have been secured it remains intelligently to divine words and letters lost by mutilation and to expand the abbreviations, but the latter have been so thoroughly listed in works on epigraphy (= the science of inscriptions) as now to present little difficulty. The same works have so classified the script-forms as greatly to simplify the act of reading the inscription, and their topical

arrangement of the subject matter of inscriptions is a great aid to interpretation.

Greek official inscriptions were chiefly recorded on marble, Roman on bronze. The latter material, being available for so many uses, proved the less enduring. But marble slabs were also converted into building material or foundation stones of ramparts, and at Rome many an inscribed stone was calcined into lime. So many were the hazards to which inscriptions were exposed that it is exceptional to find an important one in its original location. For purposes of study the modern habit of gathering inscriptions into museums is highly convenient. In Greece, besides public squares and buildings, temples were a favorite repository for inscriptions, such as state treaties, tribute and treasure lists; dress, armor, weapons and other offerings of gratitude — all with dedicatory inscriptions — made the temple a sort of museum; images of afflicted parts of the body that had been cured, with accounts of the case inscribed thereon, were offered to gods of healing, forming a sort of nucleus of an anatomical collection and a medical library. Commonest of all forms was the sepulchral inscription which began with simple announcements but grew into sounding eulogies. Among the Greek inscriptions none has been found so comprehensively important for history as the Great Rock of Behistum, but Mr. C. T. Newton, in his essays 'On Greek Inscriptions' [*Contemporary Review* (December 1876); *Nineteenth Century* (June and August 1878, reprinted in 'Essays on Art and Archæology,' p. 95, et seq.)], has set forth with great charm their collective value for history and the things pertaining to religion. At Rome, Augustus caused a succinct account of his deeds to be engraved in bronze and set up before his mausoleum. This inscription, widely diffused in the Augustus temples throughout the empire, was discovered at Ancyra (now Angora). The Monumentum Ancyranum constitutes an extensive historical document of the very first importance. The Edict of Diocletian (303 A.D.) has quite a modern ring, being a law to control mercantile "combinations in restraint of trade" by fixing a maximum price for provisions and other commodities. The Acta Fratrum Arvalium form an important memorial of a religious guild. A fragmentary black cippus unearthed in the Roman Forum (1899), supposedly near the grave of Romulus, aroused great enthusiasm. Its early date (550 B.C.) has been held to make for the credibility of the traditional account of Roman history as given by Livy rather than to give countenance to the skeptical method current since Niebuhr's time. Unfortunately, save for a few words of great interest for the comparative grammarian, the inscription admits of no more definite elucidation than the conviction that the words probably belonged to a religious prescript. The *graffiti* (wall-scratchings) of Pompeii form a large and interesting class of incidental inscriptions which comprises quotations, paraphrases, catchwords, proverbs; lovers' messages, complaints, tarryings, rendezvous; names and greetings. Among them the painted inscriptions (*dipinti*) contain election notices chiefly. The dialects of Latin are known almost entirely from inscriptions. The chief remains of the Umbrian language (dialect) are the Tabulæ Iguvinæ, seven bronze tablets found at Gubbio in 1444. They contain long ritual prescripts. Some 250 inscriptions, few of great importance save to the grammarian, represent the Oscan dialects. Etruscan inscriptions in considerable number have been found in Italy — one (supposedly) as far to the east as the island of Lemnos — but, pending the discovery of a long bilingual, these, though written in a well-known alphabet, still await definitive interpretation. The same is true of Iberian inscriptions (some 75 in number, several of between 50 and 150 letters). Runic inscriptions, in an alphabet derived from the Greek and Latin, have been found in Scandinavia and in England; the oldest (300 A.D) being engraved on the utensils found at Thorsbjerg, others on stone monuments, rocks, weapons, ornaments and coins; the longest containing 16 words. See RUNES.

Bibliography.— The general reader may consult to advantage Taylor, 'The Alphabet' (New York 1900); Kenyon, article "Writing" (in 'Hastings' Dictionary'); Whitney, 'Language and the Study of Language' (5th ed., p. 450); the histories of Egypt by Budge (London 1902) and by Petrie (London 1897–); 'Recent Lights on Ancient Egypt' (*Quarterly Review*, 200, 1904, 48–75); essays by Boscawen (*Harper's*, 88, 190); Petrie (*Contemporary*, 69, 617); Mahaffy (*Nineteenth Century*, 36, 268); Price, 'Monuments of the Old Testament' (Chicago 1900), containing facsimiles of the Rosetta Stone and other hieroglyphics, the Moabite Stone, Behistun Rock, a Tell-el-Amarna tablet and other cuneiform documents; Rogers, 'History of Babylonia and Assyria' (New York 1900); Smith, 'Chaldean Account of Genesis' (1880); Schrader, 'Cuneiform Inscriptions and the Old Testament' (London 1885); Sayce, essay in *The Living Age* (212, 1897; 360); 'Rosetta Stone' (*Open Court*, 18, 531); 'Tell-el-Amarna Letters,' edition with translation by Winckler (1896); essays in *The Living Age*, (197, 771) and *The Scottish Review* (17, 292); 'Behistun Rock,' text and translation in Rawlinson's 'Herodotus,' ii, 490–514); 'Asoka Edicts' (Rhys Davids, 'Buddhism,' pp. 220–228, London 1894); Smith, 'Asoka, the Buddhist Emperor of India' (London 1901); 'Story of the Greek and Latin Inscriptions' (*Macmillan's Magazine*, 69, 1893, 286; reprinted in *The Eclectic*, 122, 475); Mau-Kelsey, 'Pompeii,' indices and bibliography (this volume illustrates the historical value of apparently insignificant inscriptions); 'Monumentum Ancyranum,' essay by Call in *Fortnightly Review* (6, 200).

INSECT POWDER. See INSECTICIDES AND FUNGICIDES.

INSECTA. See INSECTS.

INSECTICIDE, any agent which destroys insects. This definition includes natural as well as artificial means of control, the latter being those operated by man. The most important of the former are adverse temperatures, excessive or insufficient moisture, fire, bacteria, fungi, mites, spiders, fish, reptiles, insects and birds. The artificial controls may be grouped according to their mode of action. Two principal groups are recognized: those intended to reach the alimentary tract through which they act, and those that act through the respiratory apparatus. The former are effective only with such insects as bite off and swallow pieces of plant tissue; the latter more or less also with these, but most frequently used upon insects which suck the plant juices from beneath the punctured epidermis. Beetles and their larvæ, caterpillars, grasshoppers, the larvæ of various saw flies (e.g., the currant worm), etc., all chew their food and have been most effectively controlled by arsenate of lead, Paris green, hellebore, etc., applied to the foliage before it becomes badly infected either as a spray or as a powder. Plant-lice, plant-bugs and other sucking insects are checked best by kerosene emulsion, whale-oil soap, tobacco extract or other substances that choke the breathing-pores in the insects' bodies. Some of these sucking insects are dreaded because of their great prolificacy, their small size and resistance to treatment. Gases are often used under favorable circumstances to reach insects troublesome in stored grain, among clothes, upon plants, in greenhouses, and even upon plants in the open air—these last being covered with tents or boxes while being fumigated. Since the development and use of the lime-sulphur wash which is an effective fungicide, San José and related scale insects have been more economically and conveniently held in check than by fumigation methods, though in California and other sections where citrous fruits are grown commercially, fumigation is still popular. Various chewing insects which tunnel through the tissues cannot be controlled by sprays, and are usually beyond the reach of gases. The leaf-miners, which burrow just beneath the epidermis of leaves and green stems, have never been effectively controlled, though the adults are sometimes held in partial check by sweetened poisoned sprays. Some borers (currant-borer) can be kept in check by burning the twigs they infest, by cutting them out of their burrows (peach-borer and squash borer), the method being suggested by the nature of attack. Other chewing insects (plum curculio) are jarred into kerosene. Lastly there are various oils and greases which are used upon animals and man to destroy fleas, lice, etc. Fir-tree oil in water and carbolic acid are also similarly employed.

Formulæ and Methods of Application.— Paris green and arsenate of lead if to be used wet should be mixed with a little water to form a creamy fluid, and then added to water or Bordeaux mixture (see FUNGICIDE), the former at the rate of one pound to 200 to 250 gallons. If to be used dry, use one part to 200 or 100 of finely sifted plaster, air slaked lime, road dust or wood ashes and mix thoroughly before applying. Arsenate of lead, the most popularly used poison, may be applied in strength varying from 4 to 10 pounds to 100 gallons of water, depending on the kind of insect to be controlled. These poisons are often sprayed on short clover or grass which is cut toward evening and spread thinly on bare ground to kill cut worms which destroy transplanted plants. A little molasses makes the bait more attractive. Hellebore may be mixed with water (1 ounce to 3 gallons) and a little glue or flour paste to increase adhesiveness. Each of these may be applied as a powder sifted on the plant, through a salt sack or blown upon them through a powder-gun. A little flour aids the sticking quality. Pyrethrum made from flower heads of certain plants of this genus is useful dry or in solution but soon loses its effectiveness. When powders are used, the plant should still be wet with dew or rain. Tobacco extract in several commercial forms is highly effective in controlling plant lice (aphis), if used before these insects have crumpled the leaves. Lime-sulphur wash, the best and most extensively used insecticide for scale insects, has also fungicidal properties. It is made by slaking and then boiling 20 pounds of quick lime with 15 pounds of sulphur in an iron kettle for one hour, then diluting with water to make 50 gallons and applying preferably while hot. There are various other formulæ. Because of the discomforts of making the mixture, commercial brands, of which there are many, are preferred by small growers of fruits. Miscible oils of many brands are very effective against San José and other scale insects. They are used at the rate of one part to 10 or 12 of water and are useful only on dormant deciduous trees when the temperature is above freezing and the trees not wet. Kerosene emulsion is made by intimately mixing a solution of hard soap (one pound to two gallons of hot water) with four gallons of kerosene, and diluting as needed for use with from 30 to 60 gallons of water. Pure kerosene and crude petroleum can be safely applied only to dormant plants, and then only upon bright breezy days, which will hasten evaporation. They have almost wholly given place to lime sulphur wash applied in winter. Whale oil soap is mixed with water (1 pound to 1 or up to 10 gallons), and applied as a wash or spray, Carbon disulphide may be used in confined receptacles where there is no danger of its inflammable fumes coming in contact with fire. An ounce is sufficient for from 50 to 75 cubic feet of air-tight space; and the exposure should be for 24 hours or longer. Hydrocyanic acid gas is prepared by adding cyanide of potassium (98–99 per cent pure) to water and sulphuric acid, one and one-half ounces for every 250 cubic feet of greenhouse; 100 cubic feet of nursery stock room and 125 feet of dwelling-house rooms, flour mills, trees, etc. Exposures may be from 30 to 60 minutes for trees, the former time being for plants in active growth, the latter for dormant ones; from 12 to 24 hours is usual for rooms, granaries, etc. Since these gases are violent poisons the greatest care should be exercised

in their application. Oils and greases are merely rubbed on infested animals and man. Boiling water is effective in destroying both lice and eggs in clothing, but the clothing must be boiled for hours to destroy the eggs of the body-louse and the crab-louse. Dust, tobacco-dust, etc., are useful in poultry houses for the birds to wallow in. Carbolic soap is the favorite remedy for insects or pet animals. But with all stock, poultry, pets and man, cleanliness is the great preventive.

For information concerning insecticides and their use consult bulletins of the various State Agricultural Experiment Stations and of the Bureau of Entomology of the United States Department of Agriculture and Farmers' Bulletins of this department; also the following books: Smith, 'Economic Entomology' (Philadelphia 1896); Johnson, 'Fumigation Methods' (New York 1902); O'Kane, 'Injurious Insects' (New York and London 1912); Sanderson, 'Insect Pests of Farm, Garden and Orchard' (New York 1912); Slingerland and Crosby, 'Manual of Insects' (New York and London 1914); Herrick, 'Insects Injurious to the Household and Annoying to Man' (New York and London 1914); 'Insects of Economic Importance' (New York 1915); Chittenden, 'Insects Injurious to Vegetables' (New York 1907).

INSECTICIDES AND FUNGICIDES. See AGRICULTURAL CHEMISTRY.

INSECTIVORA, an order of mammals, all of small size, usually five-toed, more or less plantigrade, and as a rule possessing clavicles. «The snout is generally long, and is often prolonged into a small proboscis. There is a tendency for the teeth to be of a generalized type and their number is often the typical mammalian 44. Moreover, trituberculate teeth, which are certainly of an ancient form, are common.» These teeth are adapted to feed on worms and insects alone. Many other evidences go to show that the type is a very old one, and Beddard thinks it may have survived because of the small size, imitative adaptiveness and nocturnal habits. Woodward speaks of the group as probably the little-altered survivors of some of the most primitive placental mammals, agreeing with the *Credonta* in their low type of brain. Most of the families may be traced back to the upper Eocene. The order falls into two divisions, (1) True Insectivores, including the hedgehogs (*Erinaceidæ*), squirrel-shrews (*Tupaiidæ*), tanrecs (*Centetidæ*), otter-shrews (*Potamagalidæ*), hutias (*Solenodontidæ*), golden moles (*Chrysochloridæ*), elephant-shrews (*Macroscelidæ*), aquatic moles (*Talpidæ*), shrews (*Soricidæ*); and (2) Dermaptera, embracing only the colugos (*Galeopithecidæ*). See HEDGEHOG; MOLE, ETC.

INSECTIVOROUS PLANTS, a collective name for plants that entrap insects and other small animals, feeding on the captures by a process of true digestion, or absorbing the results of decomposition. The best known is the Venus' fly-trap (*Dionæa muscipula*) of the order Droseraceæ. It is a native of the peat bogs of the Carolinas. The halves of the leaf blade are movable on the mid-rib, and furnished on each margin with teeth. On each half of the blade are three sensitive hairs, and the whole surface is thickly set with digestive glands. Immediately an insect touches one of these hairs the blades close, the teeth interlock, the glands exude their digestive juice on the insect, and the products are absorbed. In the common sundew (*Drosera rotundifolia*) the same result is obtained by means of stalked glands, which also function as tentacles, bending over to secure the prey; and in the butterwort (*Pinguicula vulgaris*) the margins of the leaf are the agents of capture, while the digestive juice is excreted by stalked and sessile glands on the leaf blade. *Aldrovandia vesiculosa,* an aquatic plant of southern and central Europe, has leaves which function like those of Venus' fly-trap. Drosophyllum lusitanicum, a native of Portugal and northwestern Africa, has stalked glands as well as sessile, but they do not bend over to confine prey. Their viscid secretion acts as a digestive ferment as well as a means of capture. Bladder-wort (*Utricularia*) is a floating plant common in lakes and pools. The traps or bladders, found on the submerged branches, are modified leaf organs, and present a general resemblance to the commonest prey water-fleas. The trap is entered by a door, which opens inward, but not outward, so that escape is impossible. The products of decomposition are absorbed by the cross-shaped cells lining the inner surface of the bladder. In the pitcher plants compound leaves are modified into pitcher-like receptacles, sometimes with a lid, as in the common *Sarracenia purpurea* and the southern *S. flava,* both growing in bogs. The attractions for insects are bright colors, and glands secreting nectar. Beneath the sweet bait is a slippery surface, affording insecure foothold, and insects pitching thereon fall into the secretion at the bottom. In the Old World genera Nepenthes and Cephalotus there appears to be a true digestive process; in the group of which the American genus Sarracenia is the only type, the products of decomposition are absorbed, and in the genus Dischidia, from India and Australia, pitchers store water for use by the plant. Consult Darwin, 'Insectivorous Plants.' See CARNIVOROUS PLANTS.

INSECTS (Lat. *insectum*), a class of *Arthropoda* characterized by the body being divided into three regions, that is, a head, thorax and hind-body or abdomen, and by the presence, in all but the more primitive and certain degraded forms, of wings, and of three pairs of thoracic legs. The body of insects consist of 21 segments (somites) of which six are used together to form the head, while there are three thoracic and from 10 to 12 abdominal segments. To the head are appended five pairs of jointed appendages, that is, the antennæ, mandibles and two pairs of maxillæ, while in the embryo of certain insects and in the adult *Campodea,* there has been detected a pair of vestigial appendages. Besides these appendages, there are two compound eyes, one on each side, and usually three simple eyes (ocelli) situated in the middle of the head. While the antennæ are undivided the first maxillæ are subdivided into three branches, an inner (lacinia), a middle (galea), and outer (palpifer), bearing the palpus. The second maxillæ are fused together, forming the under lip or labium; each second maxilla is composed of a lacinia, the palpus, while

INSECTS (Lat. *insectum*), a class of *Arthropoda* characterized by the body being divided into three regions, that is, a head, thorax and hind-body or abdomen, and by the presence, in all but the more primitive and certain degraded forms, of wings, and of three pairs of thoracic legs. The body of insects consist of 21 segments (somites) of which six are used together to form the head, while there are three thoracic and from 10 to 12 abdominal segments. To the head are appended five pairs of jointed appendages, that is, the antennæ, mandibles and two pairs of maxillæ, while in the embryo of certain insects and in the adult *Campodea*, there has been detected a pair of vestigial appendages. Besides these appendages there are two compound eyes, one on each side, and usually three simple eyes (ocelli) situated in the middle of the head. While the antennæ are undivided the first maxillæ are subdivided into three branches, an inner (lacinia), a middle (galea), and outer (palpifer), bearing the palpus. The second maxillæ are fused together, forming the under lip or labium; each second maxilla is composed of a lacinia, the palpus, while

PROTECTIVE MIMICRY AMONG INSECTS

vestiges of the galea occur in certain forms. In bees certain accessory appendages called paraglossæ are present. Besides the maxillæ, the so-called tongue or hypopharynx is present, being highly developed in bees; it lies on the under side of the mouth, just above the labium; in caterpillars it receives the end of the salivary duct, and is called the spinneret. Attention should also be called to the upper lip or labium, on the under side of which is the epipharynx, which bears minute taste-pits. The thorax consists of three segments, which can be easily distinguished in the primitive wingless forms (*Campodea*) and in the cockroach and locust, but in the more specialized forms as beetles, moths, bees and flies, the segments are more or less fused together and, owing to the movements of the wing muscles, are subdivided into many separate pieces. In the wasps and bees the basal abdominal segment becomes toward the pupa state transferred to the thorax. The legs as a rule end in five jointed tarsi, the last joint bearing a pair of claws with a cushion (pulvillus) between them. Insects are enabled to walk on glass, etc., by means of a sticky fluid exuded from the ends of hollow hairs fringing the cushion. They climb by means of their claws.

Insects differ from all other animals except birds and bats in possessing wings, and their presence, especially that of the muscles of flight, have greatly modified the shape and structure of the thorax. The front pair of wings is attached to the middle thoracic segment (mesothorax) and the hind wings to the metathorax. In the two-winged flies (*Diptera*) the second pair of wings are reduced and modified to form the balancers (halteres). The wings are flat sac-like outgrowths of the skin, and are strengthened by the "veins" which form hollow rods. These veins contain a trachea, so that there is a space between the air-tube and the outer wall. When the insect emerges from the nymph or the pupa, the vein is filled with blood. The spaces enclosed by the veins and their cross-branches are called cells, and their shape often affords valuable generic and specific characters. In the more primitive insects there are numerous cross-veins, and such wings as in locusts, etc., are said to be net-veined. In the *Lepidoptera* there are few cross-veins. In the *Diptera* and *Hymenoptera* the number of veins is limited, the cells also being few. The skin of insects is hard, dense and elastic, due to the deposition of chitin.

Internal Anatomy.—One of the distinctive characteristics of insects is their mode of respiration. This is effected by an intricate system of internal air-tubes (tracheæ), which are filled with air by openings (spiracles) in the sides of the body; of these spiracles there are from one to two pairs in the thorax, and eight pairs in the abdomen. The tracheæ are kept permanently open by a series of threads (tænidium) each of which makes from three to five turns around the thin tube; in this way the entire tracheal branch is provided with what at first was supposed to be a continuous spiral thread. The slit-like openings of the spiracles are guarded by a grate of stiff hairs to prevent the ingress of dust, etc. It should be borne in mind that no insect breathes through its mouth, but through the spiracles. Hence the efficacy of all oily or greasy substances in destroying every kind of insect in whatever stage of growth; wherever the oil touches the body a thin film spreads over it, covering the air-openings so that the insect soon dies by asphyxiation. Though insects have a delicate pulsating tubular heart, they have no arteries and veins, since the air in the tracheæ seeks the blood in the remotest parts of the body. The blood is thin and colorless. The aquatic larvæ and a very few perfect insects breathe by external tracheal gills, the spiracles being in such cases often absent. The genital opening is always situated near the end of the body, in front of the vent on the under side. Besides a complicated digestive canal, insects have urinary tubes opening into the end of the intestine.

The nervous system consists, besides the brain, of a chain of ganglia the greatest number of which is 13, but which become more or less fused in the more specialized groups, especially in the flies. The brain is remarkably complex, in accordance with the varied and complicated movements of the segmented body and jointed appendages, all capable of different kinds of motions.

Sense of Sight.— The compound or facetted eyes (ommatea) are composed of numerous simple eyes called ommatidia, which vary in number from 12, in *Lepisma,* to 20,000 in the dragon-fly (*Æschna*), and even 25,000 in a beetle (*Mordella*). Yet notwithstanding the wonderful complexity of these compound eyes, most insects are near-sighted, and perceive rather the movements of other animals than their exact outlines; the dragonfly and butterfly can see for a considerable distance. The simple eye probably only enables the insect to distinguish daylight from darkness, or at most very near objects. Insects, like bees and butterflies, have the color-sense, and prefer certain colors to others.

Sense of Smell.— Insects are chiefly guided by the sense of smell. This resides in the antennæ, in which there are microscopic pits filled with fluid; to this pit goes a fine nerve whose fibres end in staff-like sense cells. The number of these olfactory organs is in some insects enormous; thus in the European cockchafer there are 39,000 in the leaves of the male antennæ, and about 35,000 in those of the female; in a single antennæ of the hornet (*Vespa crabro*) are about 13,000 to 14,000. In the cockroach the abdominal cerci or feelers also possess such pits.

Sense of Hearing.— The auditory organs of the locust are drum-like ears situated one on each side of the base of the abdomen, directly behind the first abdominal spiracle; in the green grasshopper, katydids, etc., a little auditory sac is lodged in the fore-legs (*tibiæ*). It is supposed that most insects are destitute of the sense of hearing, at least auditory structures have not yet been detected; yet all sound-producing insects must have ears to hear.

Sense of Taste.— The taste organs are little pits or papillæ which resemble the olfactory organs, but which occur on the inside of the upper lips, on the epipharynx, or at the base of the proboscis and maxillæ in the bee.

The Egg and Growth of Insects.— The eggs and the fertilizing fluid of the male are produced in glands which open near the end of the body on the under side. The eggs are de-

posited by the female in the earth or in wood, leaves, etc., by means of the ovipositor, an apparatus composed of three pairs of hard appendages, and which in the wasps and bees form the sting. Most insects die on the approach of cold weather, when they lay their eggs, the species being represented in the winter by the eggs alone. The eggs hatch in spring, the embryo passing through remarkable changes.

Metamorphoses.— Most insects after hatching pass through a remarkable series of changes called a metamorphosis. The small flies, moths or beetles are not the young of large ones, but adult insects, while the most primitive insects have no marked metamorphosis, the mature locust only differing from the young in having wings; the more specialized forms as beetles, moths, wasps, bees and flies, pass through two stages of growth, that is, the larva and pupa, before becoming winged and sexually mature.

Larva.—The name was first given by the ancients to the caterpillar because they thought it masked the form of the perfect insect. Swammerdam supposed that the larva contained within itself "the germ of the future butterfly, enclosed in what will be the case of the pupa, which is itself included in three or more skins, one over the other, that will successively cover the larva." But the discovery by Weismann (q.v.) of the germs of the imago (imaginal discs or buds) in the larva completely changed our notions of the nature of metamorphosis (q.v.), and revolutionized our knowledge of the fundamental processes concerned in the change from larva to pupa or chrysalis, and from pupa to imago. Not only are the larvæ of each order of insects characteristic in form, so that the grub or larva of beetles is readily distinguished from the larvæ of other groups, or the maggots of flies from the footless larva of ants, wasps and bees, but within the limits of the larger orders there is a great diversity of larval forms, showing that they are the result of adaptation to their surroundings and mode of life.

The larvæ of nearly if not all the metabolous animals are probably secondary in their origin. Fritz Müller (q.v.) pointed out that this is the case with the larvæ of the higher insects. The larva of a beetle is popularly called a grub; that of a fly a maggot. The young of the more primitive insects, such as the cockroach, locust, all bugs, etc., which undergo an incomplete metamorphosis, is called a *nymph*. See LARVA.

Pupa.— The word pupa is Latin, meaning baby. Linnæus gave it this name from its resemblance to a baby which has been swathed or bound up, as is still the custom in southern Europe. The term pupa should be restricted to the resting, inactive stage of the holometabolous insects, that is, those with a complete metamorphosis. The typical pupa is that of a moth or a butterfly, popularly called a chrysalis. A lepidopterous pupa in which the appendages are more or less folded close to the body and soldered to the integument, was called by Linnæus a *pupa obtecta;* and when the limbs are free, as in Neuroptera, Mecoptera, Trichoptera, and the lepidopterous genus Micropteryx, it is called a *pupa libera.* When the pupa is enclosed in the old larval skin, which forms a pupal covering (puparium), the pupa was said by Linnæus to be *coarctate.* The pupa of certain Diptera, as that of the orthoraphous families, is nearly as much obtected as that of the tineoid families of moths, especially as regards the appendages of the head, the legs being more as in pupæ liberæ. The pupæ of Coleoptera and of Hymenoptera, though there is, apparently, no near relationship between these two orders, are much alike in shape, and, as Chapman pertinently suggests, those of both orders are helpless from their quiescence, and hence have resorted for protection to some cocoon or shell. But it is quite otherwise with the pupæ of Lepidoptera and Diptera, which vary so much in adaptation to their surroundings, and hence afford important taxonomical and phylogenetic characters. This, as regards the Lepidoptera, was almost wholly overlooked until Chapman called attention to the subject, and showed that the pupæ had characters of their own, of the greatest service in working out the classification, and hence the phylogeny of the different lepidopterous groups. The pupæ of the Neuroptera, Coleoptera and Hymenoptera differ structurally from the imago, in the parts of the head and thorax being less differentiated. Thus in the head the limits of sutures between the epicranium and clypeus, and the occiput and gula, are obscurely marked, while the tergal and pleural sclerites of the imago are not well differentiated until the changes occurring just before the final ecdysis. It is easy, however, to homologize the appendages of the pupæ with those of the imago of all the holometabolous orders except in the case of the obtected pupæ of the Lepidoptera (and probably of the obtected dipterous pupæ), where the cephalic appendages are soldered together.

Classification of Insects.— The number of known species of insects is from 200,000 to 300,000, but it is estimated that there are upward of a million species now living. In fact, the class of insects vastly outnumbers all other groups of animals. This is probably due to their being winged, and to their great fecundity. At present the class of insects is divided into two subclasses, that is, the (1) *Synaptera,* represented by the wingless orders Thysanura and Collembola; and (2) *Pterygota,* comprising 15 winged orders and which may be thus tabulated

Series 1.— *Heterometabola,* with an incomplete or variable though slight, degree of metamorphosis. No distinct larva or pupa state, the young being nymphs.
- Order 1. Dermaptera. (Earwig).
- " 2. Orthoptera. (Cockroach, locust, grasshopper, stick insect).
- " 3. Platyptera. (Bird lice, Perla, white ant).
- " 4. Odonata. (Dragonfly).
- " 5. Plectoptera. (Mayfly).
- " 6. Thysanoptera. (Thrips).
- " 7. Hemiptera. (Bugs).

Series 2.— *Holometabola,* or with a complete metamorphosis.
- Order 8. Neuroptera. (Corydalus, lace-wing fly, ant-lion).
- " 9. Mecoptera. (Panorpa, Boreus).
- " 10. Trichoptera. (Caddis flies).
- " 11. Coleoptera. (Beetles).
- " 12. Lepidoptera. (Moths and butterflies).
- " 13. Siphonaptera. (Flea).
- " 14. Diptera. (Mosquito, fly).
- " 15. Hymenoptera. (Saw-fly, ant, wasp, bee).

Fossil Insects.—About 3,000 species of fossil insects have been described, of these from 200 to 300 are Palæozoic, 500 Mesozoic and the remainder are Tertiary. The oldest fossil insect-remains is the wing of a supposed bug (*Protocimex*) from the Ordovician of Sweden. The wing of a cockroach (*Palæoblattina*) has been

detected in the middle Silurian of Calvados, France. From the Devonian shales of Saint John, N. B., nine species of primitive net-veined insects have been collected. The coal measures are characterized by cockroaches, primitive dragon-flies, May-flies and grasshopper-like forms, phasmids, etc., also occurring. All of the Palæozoic insects known are very primitive. Modern forms, those having a complete metamorphosis, begin to appear in the Triassic and Jurassic, where remains of beetles, a saw-fly and a moth occur. Ants, bees and butterflies date from the Oligocene and Miocene Tertiary. See FRESH-WATER INSECTS; MARINE INSECTS, and the names of groups and species, as FLIES, HYMENOPTERA, MOTHS, etc.

Bibliography.— The latest general works on insects are Carpenter's 'Insects, their Structure and Life' (London 1899), and Sharp's 'Insects' (Vols. V and VI of Cambridge Natural History 1895–99); both contain sufficient references to other works. For American insects consult Packard's 'Text-book of Entomology' (1898), and 'Guide to the Study of Insects' (1889); Comstock's 'Manual for the Study of Insects' (1895); 'Insects and Crustacea' (Vol. II, Standard Natural History 1884); Howard's 'The Insect Book' (1901). The last named contains a copious bibliography, especially to the voluminous publications of the Entomological Division of the United States Department of Agriculture.

INSECTS OF IMPORTANCE TO MAN. Startling as it may at first seem, it is nevertheless a fact that insects comprise the largest group not merely of all land animals but of all living creatures. The late C. V. Riley, curator of insects in the United States National Museum, estimated that the world's insect census contains 10,000,000 species. Later estimates, however, considerably reduce this number but the most conservative figure is 2,000,000 of which more than 350,000 have been named and described, including more than 25,000 native to North America. These latter figures are being increased at the rate of several thousand annually through the taxonomic work of entomologists.

Since the habits of insects vary widely it is natural to expect to find many species that directly or indirectly affect human interests. Of these the most useful are those (1) that fertilize the flowers of plants whose fruits or seeds or the crops grown from these are employed by man for food or other purposes; (2) those that manufacture or secrete or whose bodies constitute products similarly utilized; (3) those that prey either as parasites or predaceous enemies upon other insects or animals which destroy cultivated plants or plant products, domestic animals or their products; (4) those that act as scavengers of dead animal and vegetable matter, including the excrement of other animals; (5) and those that directly or indirectly change the character of the soil in which they pass at least part of their life history.

The first group includes a great many minute and a smaller number of large sized insects that affect man little or not at all in any other way. Were it not for them, however, very few plants, as Darwin and other noted investigators have proved, would form seeds or bear fruits. Most conspicuous perhaps of all these is the blastophaga or fig-wasp, upon which the caprification or fertilization of the Smyrna fig depends and for lack of which this choicest of all figs has until very recently failed to set fruit in America. Most conspicuous in the second group are bees which, according to Herrick, are kept by 3,000,000 beekeepers in the United States and yield honey to the value of over $25,000,000 annually — $2,000,000 in New York State alone. These insects also supply large quantities of beeswax which is used in the arts. In the second group are also the scale insects which supply certain fine waxes, cochineal, lac and its accompanying purple dye and some other materials. In the third group (predaceous and parasitic insects) are countless species belonging to the orders Hemiptera (for instance, assassin-bugs and water striders), Neuroptera (lace winged flies and ant lions), Orthoptera (praying mantis and cockroaches), Odonata (dragon-flies), Diptera (robber-flies and tachina-flies), Coleoptera (lady-bird beetles and tiger beetles) and Hymenoptera (ichneumon flies and spider wasps). In group four are many species of scavenger beetles and flies the larvæ, and in many cases also the adults, of which mimic the rôle of turkey buzzards, vultures and other creatures that feed on carrion. In group five are the larvæ of many beetles (June bugs) and moths (cutworms) which live in the soil.

While these directly or indirectly useful insects include some of the greatest benefactors of the human race, they number at most only a few hundred species, while those that play harmful rôles may be numbered by the tens of thousands. The great majority of these, the most destructive and often the most spectacular in their performance, are those that destroy cultivated crops. Martatt in the Year Book of the United States Department of Agriculture (1904, page 461) declares that the losses caused by insects in the United States alone nearly equal the then running expenses of the national government and were more than the annual cost of the schools of this country. According to Sanderson, who in his book, 'Insect Pests of Farm, Garden and Orchard,' goes into detail, the annual damage done by insects to cereals is $300,000,000; to animal products an equal amount; to products in storage $200,000,000; to forests and their products, $100,000,000; to cotton, $85,000,000; to hay and forage, $66,500,000; to truck crops, $60,000,000; to fruits, $30,000,000; to farm forests, $11,000,000; to tobacco and miscellaneous crops, each $10,000,000; to sugars, $9,500,000, an annual total of $1,182,000,000. Other estimates differ widely from these figures. For instance, Quaintance places the annual loss to deciduous fruit interests at more than $66,000,000. Texas loses annually $25,000,000 through the Mexican cotton boll weevil, an insect which has been spreading to other parts of the cotton belt and which,

it is figured, will sooner or later cost this area at least 10 times this amount annually. Webster totals the losses of cereals for 15 years due to the work of chinch bug at $350,000,000. Herrick says that the codling moth whose larvæ make wormy apples and pears destroys more than $12,000,000 worth of fruit a year.

These are but a few typical direct losses. To them must be added the cost of fighting destructive insects. To spray apple trees for the codling moth alone $4,000,000 is spent annually, to combat the San José scale $10,000,000. The New England States and the national government have already expended $7,000,000 to check the ravages of the brown tail and the gypsy moth and are spending $1,000,000 annually in this warfare. And so on almost *ad infinitum;* for every important crop has its insect enemies. Nearly 300 prey on the apple, on clover and grape each 100, on sugar beet 70, on cherry and plum each 50, to mention only a few instances.

Another important group of destructive insects includes those species that attack domestic animals, scarcely one of which but has its parasites. Some of these insects feed more or less indiscriminately upon several species of animals; others are specific to one species or a few closely related ones. Often horses, cattle and sheep are so seriously parasitized that they die, to say nothing of being weakened when less seriously attacked. The stomach and intestines of the horse are frequently so infested with botfly larvæ that it is a wonder the animal lives, much less works. The hides of cattle are often ruined because cattle botfly larvæ feed beneath the skin on the animals' backs. When the nasal passages and other head parts of sheep become densely populated by another species of botfly the animals often go insane and die. In addition to these are hornflies, gadflies, screw worm flies, lice, fleas and many other domestic animal pests, some of which may not directly cause death but all of which reduce vitality, thus wasting energy and food necessary to keep the animals in good condition. At the same time these pests may carry the germs of disease.

All this damage wrought by insects to cultivated crops and to domestic animals implies inestimable money losses. But to it must be added the also inestimable injuries to manufactured products. Naturally the first thought concerns the injuries to foods; these undoubtedly suffer most for nothing is safe unless stored in receptacles through which insects cannot burrow or thrust their eggs. But many other articles manufactured from organic materials are destroyed by insects. Certain species of insects attack wood whether used in the construction of buildings, furniture or implements. In some tropical countries termites or white ants, working always beneath the surface, devour wood until collapse occurs, thus furniture and even houses that become infested with them soon cease to be safe for human uses. In short everything of organic origin has its enemies; even books and drugs do not escape.

There are yet other important rôles which insects play — those in which they attack man directly or infect him with disease, the germs of which they carry upon or in their bodies. Because of commercial intercourse scarcely any habitable region of the globe is free from such insects as house flies, fleas, mosquitoes, bedbugs and others equally or more annoying and dangerous. Some of these species attack by means of jaws (fleas), by beaks (lice and bedbugs), by ovipositors (wasps, bees and the stinging species of ants), in most of which cases a poison is injected into the wounds though in others the mere bite or puncture is enough to produce irritation of the injured part. In other cases the insects are provided with hairs which produce a nettling or urticating effect as in the case of many caterpillars, notably those of the brown tailed moth. Again, some beetles when crushed blister the skin, for instance "Spanish fly," or cantharides used in medicine. Bees and wasps though capable of inflicting considerable pain, and, in extreme cases of highly nervous persons, even death, rarely attack human beings unless in defense of themselves or of their homes. In such cases the immediate application of an alkali such as ammonia is the best remedy.

Important as the direct attacks of insects upon man are, they are however less serious in their effects than the indirect ones; for insects which prey upon man or as in the case of the house fly, often play more important indirect rôles than on account of their mere bites or stings or contact with the human skin or with food. Certain species of Oriental mosquitoes carry such maladies as the filaria diseases of the East (chyluria, elephantiasis and lymph scrotum), others impart malaria, yellow and dengue fevers. House flies in Egypt and the Fiji Island carry purulent conjunctivitis; in other parts of the world they also spread typhoid fever and Asiatic cholera; tiny hippelate flies disseminate "pink eye" in the southern United States; fleas are said to spread bubonic plague; tabanid and stomoxyd flies are charged with disseminating anthrax by means of specific bacilli just as cucumber beetles spread the wilt or blight of cucumbers and canteloupes and as bees and other nectar feeding insects spread the fire blight of pears, apples and quinces. From these few examples, therefore, the importance of insects to man assumes a very threatening aspect. Taking this list as a whole the housefly is probably the worst offender simply through its world-wide distribution. Because of its filthy habits (the larvæ being developed in manure, the adults carrying this matter upon their bodies), and because it not only soils the surfaces upon which it alights but pollutes the human food upon which it feeds in the adult state, it is fought by cleanly housewives the world over. The cost of keeping it out of American homes is estimated by Herrick to be $10,000,000 annually. To this figure must be added the cost of fly traps, poisons and other methods of control. Similarly the cost of control of such filth carrying insects as roaches, and of such parasites on human beings as bedbugs, fleas and lice doubtless equals this enormous figure.

In spite of these expenditures, however, the number of species of our insect foes is on the increase. One cause of this is the change of conditions due to cultivation of crops. Conspicuous among the innocuous insects that have developed destructive habits is the Colorado potato beetle which in its native condition fed upon nettles and other plants of no consequence to man, but transferred its appetite to the Irish potato and the egg plant when these were introduced into its original habitat. Though now the principal insect enemy of these crops and though largely held in check by systematic spraying with poisons, it still costs the country millions of dollars in reduced crops and in expenditures for materials, machines and labor to keep it in check.

A more important factor than change of habit in the increase of our insect foes lies in commercial intercourse with foreign countries, more especially those of Europe, whose insect pests are thus accidentally imported or exported. Herrick is authority for the statement that out of 73 of our worst insect pests 37 or more than half have been imported from foreign countries. Conspicuous among these are San José scale from Australia, cotton boll weevil from Mexico, gypsy moth, currant worm, wheat midge, clover midge and Hessian fly and many others from Europe. In similar manner, but to a much smaller extent, America has disseminated insects in foreign countries. Most conspicuous among these is probably the phylloxera or root louse, which for over 200 years, as discussed in 'Evolution of Our Native Fruits' by Bailey, was a leading agent in preventing the successful commercial cultivation of European grapes in the eastern half of the United States and thus indirectly led to the development of our native species of grapes, and which when accidentally exported to Europe wrought havoc among the established vineyards, particularly of France, and thus led to the practice of grafting European varieties on American stocks, thereby not only saving the French wine industry, but also making it possible to grow European varieties on a commercial scale in the United States and perhaps in Canada. Such cases as these being possible of repetition at any time have led to the establishment of national and State regulations with respect to interstate and international transportation of nursery stock and the employment of trained men to examine such stock where grown and at ports of entry. Not only have the United States and Canada passed such laws and appointed inspectors, but many other countries are now similarly provided.

Because insects in all these enumerated ways and many others profoundly affect human interests, especially those which relate to agriculture, to manufactured organic materials, to health and to the products of such species as bees and scale insects, it is but natural that the new branch of economic entomology should have been developed as probably the most important division of biology, certainly of the animal side of this great subject. In no country of the world has the necessity for such development been so great as in America, especially in the United States. This is not only because of the enormous area of this nation, the great variety of products grown, nor the differences of climate, nor even a combination of all these factors, but also largely because the country is comparatively new, because the insect pests introduced from other countries have generally been brought in without the natural enemies that kept them more or less under control where they were indigenous, and finally because many of our native species have left their original food and developed tastes for the new plants, animals or the products of such brought within tempting reach of them. While economic entomology had its inception in Europe, necessity and American progressiveness and inventiveness have so fostered and encouraged it on this side of the Atlantic that the United States not only leads the world in its insect investigations and successful methods of control, but it employs a larger force of official economic entomologists than do all other countries of the world put together.

Still further, economic entomology is one of the leading subjects in the curriculum of all leading agricultural colleges and schools because it is required that all teachers and investigators of agriculture, all farm bureau or county agents, all agricultural extension specialists, and all inspectors of nursery stock, must have as thorough a grounding in this subject as in botany, chemistry and physics in order to hold staff positions in the National Department of Agriculture, those of the respective States, or in the colleges and schools which teach agriculture from the practical standpoint. Herein lies another item of expenditure that aggregates millions of dollars annually and thereby increases the enormous figures presented. But all this expenditure and study is necessary and justified because it is essential to man's well being that these foes shall be destroyed in order that man may have his rightful dominion over the earth and its creatures.

For methods of controlling insects (see INSECTICIDE) under which title will also be found a list of important books and other writings which deal with the control of these creatures by natural and artificial means.

M. G. KAINS,
Horticultural Consultant.

INSESSORES, in-sĕ-sō′rēz, a discarded term in ornithology designating a group styled "perchers," which included the majority of the smaller and more familiar birds. The term has been abandoned because the group denoted by it is a purely arbitrary one.

INSIDIOUS FLOWER-BUG. See FLOWER-BUG.

INSIGNIA. See MILITARY INSIGNIA.

INSKIP, John S., American clergyman, evangelist and editor: b. Huntington, England, in 1816; d. Ocean Grove, N. J., 7 March 1884. He was brought to America in 1820, the family settling first at Wilmington, Del., and then at Marshallton, Pa. In 1836 he entered the ministry of the Methodist Episcopal Church, joining the Philadelphia Conference, and serving prominent churches in that Conference, the Ohio, the New York East and the New York Conferences. When pastor at Springfield, Ohio, he introduced the custom of having families sit together. Previous to this men sat on one side of the church and women on the other in Methodist worship. He was tried and censured by his Conference, but appealed to the General Conference of 1852 which exonerated him. He was chaplain of the Brooklyn 14th regiment the first year of the war but resigned on account of poor health. From 1873 until his death he was editor of *The Christian Standard and Home Journal* of Philadelphia. He was one of the founders of the National Campmeeting Association and personally conducted more than 50 camp meetings. He was

an evangelist of unusual ability. In 1881–82 he took an extended evangelistic tour, conducting meetings in England, India and Australia, traveling in the year 31,000 miles, conducting over 500 public services, and witnessing over 5,000 conversions. He wrote more than 160 columns of editorial matter for his paper on the trip and conducted an extensive correspondence besides. He was the author of 'Methodism: Explained and Defended' (Cincinnati 1851); 'Songs of Triumph' (Philadelphia 1882). Consult McDonald, William, 'Life of John S. Inskip' (Boston 1885).

INSOLATION, heating by direct exposure to the sun's rays. In geology it has significance in the process of weathering by heating and cooling of rock surfaces with resulting expansion and contraction and shattering of the rock mass. See EXFOLIATION.

INSOLVENCY. In a popular sense the word insolvency applies only to persons without property or means sufficient to satisfy their creditors. The legal definition embraces all who are unable to pay their debts at maturity in the ordinary course of business, even though they may possess assets exceeding their liabilities. A failure to meet overdue obligations renders a person liable to proceedings against him in a court of insolvency, in which his assets may be taken into the possession of the officers, marshaled and distributed to his creditors. Should there be an amount in excess of what is required to pay the creditors and the expenses of administration, the balance so remaining is the property of the debtor. From a very early period in the history of civil government, laws have existed providing for proceedings by creditors against insolvent debtors, by which the debtor's property could be taken from his possession, to be held by another as a trust fund to be applied to the payment of his just debts. In case of an insufficient amount to pay all debts in full, provisions are usually made for a *pro rata* distribution. These laws have generally provided for classes of preferred debts, payments of which were to be made in full, even though such payments exhausted the entire assets. Preferred claims commonly included all claims of the government or state, and often claims for labor to a limited amount, and claims for the necessaries of life. Provisions are usually made for the exemption of certain articles to the use of the debtor, not to be included in the assets. The Constitution of the United States provides that Congress may establish uniform laws on the subject of bankruptcy throughout all the States, and the first act upon that subject was passed in 1800, since which time there has been some Federal bankruptcy law, with brief interregnums. A uniform national law upon the subject now exists. The first act of Congress upon this subject provided for proceedings by the creditors only, but in 1841 an amendment provided for voluntary proceedings by the debtor, by which he could surrender his property and obtain a discharge from all of his debts, provided he had been guilty of no fraud. In the absence of a national law on the subject of insolvency, the States all have authority to enact and enforce laws upon that subject. The Federal act now provides for voluntary proceedings by the debtor, as well as proceedings against him by the creditors, with provisions for his discharge. The various State acts have usually contained such provisions. The Federal act during its continuance suspends all State insolvency laws covering the same ground. See BANKRUPTCY LAWS.

INSOMNIA, a disordered condition of the body characterized by sleeplessness. It may be due to toxic condition, mental or physical exhaustion, or other causes. The usual treatment is directed to removing the cause. Hot baths, hot food, applying heat to the soles of the feet are also applied with considerable success in many cases. See SLEEP.

INSPECTOR, or **INSPECTOR-GENERAL,** in military affairs, terms of somewhat vague significance. There are inspectors-general of cavalry, infantry, artillery, engineers, aviation, militia and volunteers, whose duties are really those which their names infer — viz., the periodical inspection of the several corps of their respective arms, and the pointing out of deficiencies, the corps being under command, however, of its own officers, and not of the inspector-general. The inspectors-general of musketry and gunnery instruction are charged with the direct superintendence and ordering of such instruction throughout the army. In the medical department the inspectors-general of hospitals constitute the highest grade of surgeons. See ARMY ORGANIZATION.

INSPIRATION, in theology, the communication by the Holy Spirit, to writers and speakers, of a portion of the knowledge and feeling of God, in such fashion that they can be communicated to other men; especially used in relation to the Bible. On the fact of inspiration rests all attribution of divinity to the sacred writings above any others; but theories of its method and extent have necessarily changed with the advance of critical knowledge. They have never had an authoritative pronouncement even from the Catholic Church which allows liberty of judgment on this; the Bible not holding the supreme place there as in Protestant bodies, and the latter being too divided for a credal statement on this point, by the very causes which call for one. All theories rest not only on the necessary implication of divine character in the Bible, but on two specific passages: 2 Tim. iii, 16; "All Scripture is given by the inspiration of God, and is profitable for doctrine" (Revised Version, "Every Scripture inspired of God is also profitable for teaching," which does not relinquish the claim of inspiration); and 2 Peter i, 21, "Holy men of God spake as they were moved by the Holy Ghost" (Revised essentially the same). The Scriptures were the Old Testament.

The early Church did not generally dwell on theories of inspiration, regarding it as a passive "ecstasy" in which divine truth was communicated, but rarely going on to its effects on the inspired writings or the methods which produced them. Origen, however, the great builder of doctrinal framework, formulated an exact theory of "plenary" or entire inspiration, which preserved the writers from all faults of memory, and left no iota either incorrect or superfluous in Scripture. But others held that all believers were inspired in different degrees; as this made all believers infallible interpreters of the Scriptures, the perilous nature of such a doctrine led to the opposite one, that there was an inspired official depositary of interpretation as well as an inspired canon of writings. The mediæval schoolmen evolved the theory that there were two kinds of inspiration in the Scriptures: direct, found where moral and doctrinal truths are directly taught; and indirect, in historical passages, whence ethical truths can only be derived by allegorical interpretation.

Regarding inspiration not as a purpose but a method, there are three explanations within the limits of orthodox Christianity: the "plenary" or verbal, the dynamic, and what may be termed the "irradiant" theories. The remaining one, which makes the inspiration only that common to all human beings — who are part of the divine mind — and having no part in any special revelation, is really not a theory of inspiration at all, as it holds that there is none; that all things are parts of the world's evolution, and the sacred writers and the Bible were evolved like the rest, though the latter is the greatest moral product of the world, and to be reverenced in the moral rank as we reverence the greatest writers and thinkers in theirs.

In the early uncritical ages of the Protestant churches, the universal and obvious theory of inspiration was the plenary. The original text of the Bible was dictated word for word by the Holy Spirit, the writers being merely penmen, or media on whom were impressed certain phrases, which must not be varied on peril of distorting the divine revelation. The words of Scripture thus transmitted are God's words, to each reader as if spoken directly to him by the Deity, and no matter to what subject they relate, be it doctrine or history, the origin of man or the duty of man. That there are different styles, corresponding to different writers, means only that God has accommodated his expressions to their natures, for his own utilities. Hence the least particle in the Scriptures is surcharged with meaning, and if anything seems in conflict with science, history, or other portions of the Bible, it arises from corruption of text, bad translation or other change from the actual revealed language. This is the only theory with perfect logical continuity; unhappily it can only be maintained, in face of the increasing body of knowledge of texts, facts and natural ethics, by those willing to abnegate their own right of criticism wholly in favor of their own infallible interpretation. Indeed, the chief argument for the latter is that the divine purpose would be defeated, if its intention in giving the revelation were made null by the misunderstanding of fallible human faculties.

The dynamic theory is the first step outside this bulwark enforced by the impossibility of maintaining verbal inspiration and relegates the divine agency to an indirect function. In place of its dictating the exact phraseology and the precise facts, the writers are so filled with divine force that for all purposes of conveying the essential divine purpose, that of showing the truths of sin and danger and the path of salvation, they are a portion of the divine and incapable of error. Under this theory the writers are left a free hand, according to their own limitations and those of their age, in dealing with narrative facts or their own guesses at them; but are guided explicitly in all matters of faith and morals. In order to be received, the revelation had to be accommodated to the mental conditions of different ages; and men of each received guidance from God to present it so that it was true in relation to them, and remained so for all ages under all conditions. The warrant of the Bible is its incomparable and superhuman system of ethics, and its proof of divine origin is that evident superiority to all human devices.

The "irradiant" theory is a recent one, and a step farther from the old claim of entire divinity. In this view the record as such has no divinity, nor infallibility of any kind. There is a divine revelation, but it acts by generating moral ideas in certain great selected men, and which, once generated, are left to fight their way and take their chance like the other useful ideas of the world, and undergo disbelief and mutilation, with the certainty that according to God's purpose truth will prevail at last. The proof of divinity in Christianity lies in the fact that its moral truths are the greatest in the world, and were original with it.

Another theory is based on evolution, in this both revelation and inspiration are dispensed with, and there is retained only that enlightenment which comes with all development through environment and the laws of variation. In human progress lies the real divine revelation. The Bible is a purely human book, but the greatest of all books, and as such should retain its place as the foundation of our religious structure.

INSTALLATION, the act of giving possession of an office, rank or order with the accustomed ceremonies, applied especially to the ministerial or pastoral office in the church. The term is now generally used for a formal introduction to any office.

INSTERBURG, Prussia, town in the province of East Prussia, at the confluence of the Angerapp and Inster, 57 miles east of Königsberg. The town church is famed for its wood carvings. Other churches are three Evangelical, one Roman Catholic and a synagogue. Its industrial establishments include iron foundries, flax-spinning mills, machine shops, cement works, leather works, etc. It has a good trade in cereals, flax, vegetables, lumber, etc., and horse-breeding is extensively carried on. The town was founded in the 14th century by the Knights of the Teutonic Order. In 1583 it received civic privileges and thereafter grew

apace. It was besieged by the Swedes in 1679. A fire nearly destroyed it in 1690 and a pestilence decimated its population in 1710. Pop. 31,627. Consult Töws, 'Urkunden zur Geschichte des Hauptamts Insterburg' (Insterburg 1895–97).

INSTINCT. Every organism is born with a number of tendencies to behave in certain specific ways when confronted with stimuli to which they are adequate. These tendencies not only increase in number and complexity as we pass from the protozoa to the primates, but also vary similarly within a single organism. The amœba inherits three simple reactions; tendencies to move toward certain stimuli, to turn away from others and to engulf still others for food. Man, at the other extreme, has innumerable innate dispositions, and they vary in complexity, as, for example, tendencies to cough and to sneeze, to fear and to become angry, to associate with his kind and to think to a conclusion. All these tendencies are instinctive, and instinct may be defined as "the general name for these innate tendencies" (Titchener), or as a "congenital mode of behavior dependent upon inherited dispositions within the lower brain centres" (Morgan), or again as "a combination of congenital responses unfolding serially under appropriate stimulation" (Watson). Despite differences in emphasis and systematic treatment these three definitions are in agreement as regards essentials, and all three ultimately refer instinct to the nervous system. It is a mistake, therefore, to suppose, as is popularly supposed, that instinct is a faculty provided by Providence to direct the actions of animals and opposed to the faculty of reason furnished for the guidance of man. Such a view purports to explain but, in fact, explains nothing, and it overlooks the fact that man probably has more instincts than the lower animals. If, then, an instinct is a tendency which in the final analysis belongs to the nervous system, then it follows that we must go to biology, particularly physiology, for a detailed description. Nevertheless, instinct has also a psychological aspect, instinctive acts are accompanied by mental processes, and some mental patterns have as their physiological correlates certain instinctive tendencies. Much needless controversy has arisen through a confusion of the biological and psychological points of view, and confusion can only be avoided by considering the two aspects separately.

Biology.—The biologists have as yet done little more than to clear the ground for future work; the detailed study of instincts is yet to come. Furthermore, no classification of instincts has thus far found general acceptance. Instinct may, however, be roughly marked off from the physiological reflex on the one hand and from habit on the other. The former, of which the knee-jerk, heart-beat and eye-wink will serve as examples, is as a rule confined to a single group of muscles whereas instinct usually involves the entire organism. Habit is a tendency which is acquired during the lifetime of the organism. We cannot, of course, push these distinctions too far; there is no sharp line of demarkation between reflexes and instincts, and not only are many habits based upon instinctive tendencies but many instincts are not perfected at their first appearance. The results of the experimental investigations may be summarized as follows: (1) Not all instincts make their first appearance at birth; in the vertebrates, at least, new tendencies appear at different stages of growth particularly between birth and puberty. In white rats, for example, the instinctive act of "face washing" does not appear until the 12th day, play about the 15th day and sexual activities about the 65th day; the monkey does not as a rule begin to walk before the third week, to make characteristic vocal sounds before the ninth week and the sexual instincts do not appear until the end of the first year. (2) We have seen that instincts are not always perfected when they make their first appearance. When this is the case, it sometimes happens that the characteristic act of a species may be modified or even completely inhibited by subsequent experience. Baltimore orioles reared in captivity and in isolation developed a song quite different from the usual song of their kind; English sparrows reared with canaries gave up the chirp of the sparrow for the peep of the canary; the tendency of a pike to strike at a minnow was completely inhibited after successively bumping against a glass plate inserted in the aquarium and in front of the minnow. (3) The less selective instincts like rest, sleep and play are extraordinarily persistent although in the human organism they may repeatedly find new forms of expression; others, however, which seem to be conditioned upon the bodily state of the organism as, for example, the various instincts of the mother in caring for her young, may wane and fade out. (4) Yerkes has found that some instincts like savageness, wildness and timidity in rats, and the direction of whirl in the dancing mouse are hereditary traits.

Psychology.—We turn to the psychological aspect of instinct. Here, although even less is definitely known than on the biological side, three problems stand out in bold relief. We have to investigate the mental processes that are present in the instinctive act (the action consciousness), to describe other mental states which are conditioned upon instinctive tendencies, and to work out the relation of instinct to meaningful experience. As regards the first, work on the human organism seems to show that the instinctive is of the same type as the sensori-motor act, i.e., the perception of the object touches off the reaction, there is necessarily no conscious representation of the determination to act or of the action's end. We have no reason to suppose, therefore, that, for instance, the wren is in the least aware of what it is doing or why it is doing it when it builds its nest. This does not mean, however, that, accompanying the instinctive act, there is no psychological experience. On the contrary we may safely assume that even in the lowest forms of animal life some sort of sensory experience releases the disposition and to an extent determines the subsequent course of the action. Secondly, psychologists are agreed that, particularly in the case of the grosser emotions, the emotive is an instinctive consciousness, and the psychology of the emotions is, therefore, in a sense a psychology of instincts. In fear, for example, the vaso-constriction, the rapid heart-beat, the spasmodic respiration, the glandular secretions are touched off by instinctive tendencies, and the correlated patterns of organic sensations and feelings form the core of the mental experience. Aside from this general statement little is established as regards either a detailed description of the emotions or of their number and variety. It is, perhaps, because of their instinctive basis that psychology has found it difficult to bring the emotive instincts under experimental control. Finally, the more we learn about instinctive tendencies the more apparent it becomes that the situations from which they proceed are meaningful, but we need not suppose that the organism is necessarily aware of the meaning. The chick in the egg feels (we may only guess as to its nature) a vague discomfort, and the complicated reaction by which it makes its egress from the shell is released. How this particular tendency to react thus to this particular situation originated is a question which cannot be answered until biology has given us a satisfactory theory of the origin and transmission of instincts — a task that must await a more detailed description of the nervous correlations involved. HARRY P. WELD,
Assistant Professor of Psychology, Cornell University.

INSTITUTE OF FRANCE, The, official name for a group of learned societies in France, having for object the fostering of some branch in art, literature, science or philosophy. At present it consists of five sections, the official names of which are: (1) L'Académie Française; (2) L'Académie des Inscriptions et Belles Lettres; (3) L'Académie des Beaux Arts; (4) L'Académie des Sciences; (5) L'Académie des Sciences Morales et Politiques. The creation of the Institute of France was decided on by the Convention in the Constitution of the year III (1795); Section 298 of that Constitutional Law reads as follows: "There is, for the Republic, a national Institute entrusted with the care of collecting all discoveries, and furthering the progress of arts and sciences." The Charter of Foundation, however, admitted only three sections: (1) "Sciences Physiques et Mathématiques; (2) Sciences Morales et Politiques; (3) Littérature et Beaux Arts," avoiding the denomination of Academy, which was considered as reactionary by the new-born republic. Among the 144 members of the Institute, 66 belonged to the first section, which, at that time, was deemed the most important of the three. One-third of the members were appointed by a decision of the Directory; these first 48 members chose themselves a new contingent of 48; and finally these 96 elected the third and last contingent, also of 48 members. The Directory granted to each of these an annuity of 1,500 francs ($300) which was then deemed sufficient to keep a man above the poverty line. To-day, although it is no longer deemed sufficient, as every visitor to Paris must know, this annuity has not been raised, although Napoleon wished to increase it to 5,000 francs; in fact, it amounts only to 1,200 francs, as 300 francs are deducted every year in order to create a fund which is redistributed, under the form of *jetons de présence* (attendance fees), to the members who attend the sittings of their respective academies. The Institute of France was introduced to the public in the *Salle des Cariatides,* of the Louvre, which was splendidly decorated for the ceremony, which took place on the 15th *Germinal of the year IV* (4 April 1796) and was attended in great solemnity by the State Ministers, the Diplomatic Corps and a magnificent crowd; from the speeches which were delivered, from the grandiose ceremony of inauguration, "the impression was created," said M. Raymond Poincaré, in his address, on the Commemoration Day of the Centenary of the Institute (in 1895), "that a great thing had been achieved, and public homage was paid to the Unity of Sciences by a rejuvenated nation." In 1805 Napoleon, who, as First Consul, had already given a special costume to the members of the Institute, decided that the latter should have their own palace; the Institute was therefore transferred to the palace which faces the Louvre over the Pont-des-Arts, and which bears the name of Palais de l'Institut. Its library (which must not be mistaken for the Bibliothèque Mazarine, in another portion of the same building), consists of 500,000 volumes. The name Academy which had been suppressed by the convention was revived by Louis XVIII in 1816; and the Académies were restored to their own former charters; since 1870, the five of them meet together every year in a solemn public assembly, on the 25th of October. On that occasion some of the prizes granted by the Institute are delivered to the winners. In its present condition, the Institute has 231 ordinary members (*membres titulaires*) to whom must be added 296 correspondents; some of the latter are foreigners, and we may mention among the Americans who are *Correspondants de l'Institut*: Edward Charles Pickering, George Ellery Hale, William Morris Davis, Albert A. Michelson, Paul Wayland Bartlett, James Mark Baldwin, Charles William Eliot. The most important of all the prizes which are given by the Institute is the Prix Osiris (triennial), which amounts to 100,000 francs. This prize was established by Baron Osiris, "for the purpose of rewarding the most remarkable work in science, or in letters, or in industry and generally in whatever concerns public welfare." The *Prix Osiris* was granted in 1903 to Dr. Roux in consideration of his researches on *serums* and transferred immediately by him to the Institut Pasteur of which he is the director; in 1906 the prize was awarded to M. Albert Sorel in consideration of his historical researches. Many other prizes have been offered to the Institute by rich individuals: the oldest of these liberalities was made as far back as 1819 when Baron de Montyon bequeathed an annuity of 37,000 francs for the purpose of rewarding "the most virtuous actions and the books which may best further the progress of morality." In 1886 the

Château de Chantilly with its very valuable library (Musée Condé), was given to the Institute by the Duc d'Aumale; in 1897 the Château de Langeois, one of the finest types of French architecture, was given by M. Jules Siegfried; in 1906 the private house of M. Thiers, first President of the 3d Republic, was bequeathed by Mlle. Dosne, his niece; in 1900 M. Jean Debrousse bequeathed 1,000,000 francs "to be used by the Institute as it will deem most proper." Many other donations and legacies have been made to the Institute and to each of the five Académies. Every year numerous prizes for hundreds of thousands of francs are distributed to men of letters, artists, men and women in difficult circumstances, etc., so that the Institute acquires further prestige every year. To be "Membre de l'Institute" is a great honor of which Napoleon himself was very proud; the foreign correspondents may be struck off the list when the Institute considers that they have failed in any particular circumstance: the most prominent case of such elimination was that of the German professors who, at the beginning of the European War, tried, in their 'Address to the Civilized World' to justify the invasion of Belgium, etc. Among the German correspondents who were struck off the list, we may mention Herren Vilomowitz-Moellendorf, Dorpfeld, Harnack, de Groot, Karl Robert, Wundt Riehl, Liebermann.

Let us now examine each of the five Académies.

I. The Académie Française (such was the original name), was founded by Cardinal de Richelieu, Minister of Louis XIII, in 1635. A few years before, the poet Antoine Godeau and his cousin Conrart, secretary to the King, used to meet every week at the latter's house which was situated at the corner of Rue Saint Martin and Rue des Vieilles-Etuves, with a few distinguished friends of literary taste. When Richelieu, in 1635, inquired of these gentlemen whether "they would not like to be formed into a company under the authority of the state," they could not but accept such direct invitation. Richelieu understood from the beginning the important part which the new-born Academy could play in the development, unification and purification of the French language; and his ambition, among others, was that French should acquire the same perfection, importance and power of domination as Latin and Greek. As early as 1634, that is to say one year before it was officially constituted the Academy decided to prepare a 'Dictionnaire de la Langue Française'; the first edition of which was published only in 1694. Since that time seven revised editions have been published; the second in 1718, the third in 1740, the fourth in 1762; the fifth, under the convention which had first suppressed it; the sixth and the seventh in 1835 and 1877. The Academy is now preparing the eighth edition. When Richelieu died in 1642, the Academy chose, as patron, Chancelier Séguier, who invited the members to hold their weekly meetings in his own private hotel. But, when Séguier died, the Academy did not seek a patron among state ministers, or great personages who might perhaps become an obstacle to its independence; it applied directly to the king himself, believing, which was right enough, that the king as a patron would remain a stranger to all coteries and petty intrigues which were more or less favored by ministers. In fact under the protection of Louis XIV, during 42 years, the Academy enjoyed great freedom, independence and even privileges such as a right to two invitations at all official festivities at the court, the right of appeal direct to the king without the medium of his state ministers Besides, it was invited by Louis XIV to make its permanent abode in the Louvre, the king's own palace, from which it was removed only in 1793 by the convention. The rooms occupied by the Academy were situated on the ground-floor and are at present part of the French Sculpture Gallery, (Salles du Puget and Salle des Coustou). Toward 1693, when La Bruyère was elected, the Académie Française was composed of a most brilliant Pleiad of writers who greatly cooperated in making the reign of Louis XIV one of the most glorious and in giving to the history of French literature an unparalleled splendor; if indeed Corneille and Colbert were dead there were still Bossuet, Fléchier, Fénelon, Racine, La Fontaine, Boileau, Perrault, Fontenelle. The next generation of Academicians was not so brilliant: the "Grande Seigneurs," great dignitaries and other personages of high station, finally considered that certain seats in the Academy belonged to them or their caste as a sort of birthday right: three dukes de Coislin, for instance, were Academicians; even to-day the "parti des ducs" still exists under the "Coupole"; it means that the old aristocracy is always represented in that ancient institution, but it is right to say that members of the nobility are elected as much on account of their literary achievements as of their aristocratic origin. During the 18th century, however, some men of great literary fame belonged to the Academy; among them we must mention d'Alembert who wrote the celebrated preface to the 'Encyclopédie'; he was one of the most appreciated men in Europe. Frederick II, King of Prussia, wanted him to live in Berlin and, for that purpose, offered him the presidency of his own academy; Catherine, Empress of Russia, wanted him to educate her son; fortunately he refused these kingly and imperial offers in order to devote himself to the great cause of emancipation which was more or less outlined in the 'Encyclopédie' and which was to triumph in 1789 and the following revolutions. Voltaire, Duclos, Condorcet were also members of the Academy. During the second half of the 18th century the whole of Europe turned its attentioon to that Institution; all the monarchs and princes who came to Paris (the King of Denmark, the King of Sweden, the King of Prussia, the Imperial Russian Crown Prince, etc.), made a point to attend at least one of its meetings. On 28 June 1917, at the reception of M. Alfred Capus, General Pershing was solemnly entertained at the Palais de l'Institut. Although the great French Revolution had been prepared by some of the most distinguished members of the Academy, the latter was finally considered by the convention as a reactionary institution smacking too much of the *ancien régime* and ancient prerogatives. It was suppressed in 1793. It revived when the Institut de France was created in 1795, under another name as the Classe de Langue et Littérature Françaises. In 1816, however, Louis XVIII restored it to its former name of

Académie Française which has been retained ever since. About the same time (1819), Baron de Montyon left by testament to the Academy an annuity of 37,000 francs which is distributed every year in the form of two prizes (*prix Montyon destiné aux ouvrages les plue utiles aux mœurs;* and *prix de vertu, fondation Montyon*). Since that time many prizes have been instituted by the Academy, thanks to the numerous gifts, donations and legacies which have steadily increased its financial power. The following list of prizes, although incomplete, distributed by the Academy, will give an idea of its social and literary importance:

Prize	Francs
Montyon	37,000 yearly
Souriau	1,000 "
Marie Lasne	1,800 "
de Sussy	8,000 "
Camille Favre	13,500 "
Lelevain	1,500 "
Emile Robin	1,000 "
Lange	6,500 "
Buisson	3,500 "
Louise Varat-Larousse	4,500 "
Savourat-Thénard	5,500 "
Pérou	1,000 "
Bausa-Gessiomme	2,500 triennial
Agemoglu	1,900 yearly
Rigot	3,200 "
Jules Favre	1,000 "
Passemard	1,000 "
Anonymous	1,000 "
Anonymous	4,500 biennial
Peyrard-Beaumanoir	3,000 yearly
Broquette-Gonin	12,000 "
Alexandre Broquette-Gonin	8,000 "
Tremblay	1,000 biennial
Bigot	6,000 "
Baron and Baronne Léopold Davillier	6,000 yearly
Argut	4,000 "
Cavelan	6,000 "

All these prizes are generally awarded, according to the wishes of their founders, to such persons, male or female, as live an exceptionally virtuous and laborious life, and are considered as having reached a high level of family, social or moral perfection. Nearly all prizes are awarded annually: the following conditions are required of the competitors; the action eventually to be rewarded must have been continued into the last two previous years. A detailed memorandum, with approved certificates, signed by local authorities, and giving full information concerning the competitor's eventual right to a prize, must be sent to the *Chef du Secrétariat de l'Institut.* Such memorandum must not be signed nor sent by the competitor himself. The latter's name, Christian name and place of residence must be placed at the head of the memorandum. The number of academicians is 40. Whenever one of the seats becomes vacant, the Academy elects another member to take the place of the deceased. The new member is formally admitted into the "illustre compagnie" at a solemn and pompous meeting; on such occasion each "immortel" wears his green uniform, cocked hat and sword; there is a restricted number of seats for the public; in fact it is very difficult to get admission; as a rule the audience is of an extremely select and aristocratic character. The reception consists essentially in the exchange of two speeches, rather lengthy, between one member of the academy and the "récipiendaire," the latter devoting his remarks to the virtues, talents and achievements of his predecessor, whilst in his own *discours,* the other party never forgets to impress upon the new member that the academy has secured immortality for his name, if not his literary works; in a harmless, humorous and half innocent manner, he unloads upon the newcomer a number of appropriate remarks in which the audience takes a great delight. Perhaps one of the most interesting "*discours académiques*" in that respect, was the one delivered by M. Ernest Lavisse at the reception of Monsieur Raymond Poincaré, the President of the French Republic (in 1909).

The following is the list of the living members of the Academy in order of seniority:

Othenin P. de Cléron, Comte d'Haussonville	Alexandre Félix Joseph Ribot
Charles Louis de Saulces de Freycinet	Maurice Barrès
Louis Marie Julien Viaud (Pierre Loti)	Jean Richepin
Ernest Lavisse	Raymond Poincaré
Paul Bourget	Eugène Brieux
Jacques Anatole Thibault (Anatole France)	Jean Aicard
Gabriel Hanotaux	René Doumic
Henri Léon Emile Lavedan	Marcel Prévost
Paul Deschanel	Monseigneur Duchesne
Edmond Rostand	Henri de Régnier
Frédéric Masson	Denys Cochin
René Bazin	Hubert Lyautey
Etienne Lamy	Emile Boutroux
	Alfred Capus
	Pierre de la Gorce
	Henri Bergson

II. The Académie des Inscriptions et Belles-Lettres was created by Colbert in 1663. It was known first under the name of La Petite Académie, then of L'Académie des Médailles, then of L'Académie Royale des Inscriptions et Médailles in 1701, and finally under its present name since 1716. It was temporarily suppressed by the Revolution and revived when the Institut de France was created in 1795. The Académie des Inscriptions is interested mainly in historical studies and investigations concerning numismatics, all sorts of ancient documents and inscriptions, living and dead languages. Every year it distributes many prizes to the students and writers whose historical researches appear to be useful. The prix Gobert (10,000 francs, yearly), for instance, is intended to reward "the most learned and exhaustive research concerning French history." More than 80,000 francs are offered in prizes every year by the Academy for similar works and researches.

III. The Académie des Sciences was also created by Colbert under Louis XIV, in 1667. The meetings were held first in Colbert's library and, from 1699 to 1793, in the Louvre. It consists of 78 members; like the Académie Française and the Académie des Inscriptions et Belles Lettres, it was temporarily suppressed by the Convention and revived when the Institut was created in 1795. It is divided into the following sections: geography and navigation, geometry, statistics, mechanics, astronomy, botanics, medicine and surgery. The Academy of Science offers many annual prizes ranging between 500 to 10,000 francs. One prize (Prix Pierre Guzman) of 100,000 francs will be awarded to any one who will discover the means of communicating with a star other than the planet Mars, that is to say, who will make a sign to a star and receive an answer to that sign. Another prize of 100,000 francs will be awarded to the person who will discover the means of curing Asiatic cholera.

IV. L'Académie des Beaux-Arts was created in 1648 by a famous artist, Charles Le Brun, under the patronage of M. de Charmois, an influential courtier, under the name of

Académie Royale de Peinture et de Sculpture. The 12 initial members of that company opened a school (École du Nu); later on, in 1656, the king invited them to hold their meetings in the Louvre where they remained until their academy was temporarily suppressed by the Convention. In 1666 the Académie de France à Rome, a school where French artists completed their studies, was created by the Académie Royale de Peinture et de Sculpture with the co-operation of Colbert. That school is located at present in the Villa Médicis; the École des Beaux-Arts, in Paris, is under the control of the Académie des Beaux-Arts. There are 51 members in the Academy of Fine Arts which consists itself of the following sections: painting, sculpture, engraving, music. Numerous prizes are awarded every year to artists, students, etc. . . . in order to encourage the progress of fine arts and, at the same time, to guide public opinion which is sometimes slow in recognizing the merits of artists.

V. L'Académie des Sciences Morales et Politiques was created under the name of Classe des Sciences Morales et Politiques in 1795, as one of the sections of the Institute. It was suppressed quietly in 1803 by Napoleon who did not give any reason for his decision. It may be that the inquisitive spirit and criticisms of that Institution on political matters, social and religious controversies did not please a despotic sovereign; nobody, however, has been able to discover any proper justification of such sudden suppression. It was restored under its present name by Louis-Philippe, in 1832, when it joined the four other academics in the Palais de l'Institut. It is divided into five sections: (1) Philosophy, (2) Morals, (3) Legislation and Jurisprudence, (4) Political Economy, Statistics and Finance, (6) General and Philosophic History. The number of Academicians is 51. Some important prizes are awarded every year, some of them amounting to 10,000, 12,000 and 15,000 francs; the prix François Joseph Audiffred (15,000 francs), was awarded, in 1917, to Cardinal Mercier, the great unconquerable Belgian prelate who has deserved universal admiration. The list of these prizes increases steadily from year to year, thanks to the generosity of rich individuals. Anybody interested in the prizes awarded by the Institut de France may have full particulars regarding the conditions, the subjects proposed, etc., by applying to the Secrétaire Perpétuel of any one of the five academics. The Institute publishes also every year a booklet giving the names of all the members and correspondences of each academy, under the title of 'Annuaire de l'Institut.'

MARC DE VALETTE.

INSTITUTE OF SOCIAL SERVICE, American. See SOCIAL SERVICE.

INSTITUTES OF THE CHRISTIAN RELIGION, The ('Christianæ Religionis Institutio'), by which John Calvin laid the foundations of Calvinism, stands unique among books that have had immediate, deep, wide, and lasting influence on Christian thought and life not alone for the author's youth, the comparative brevity of the theological studies that preceded it, and the speed at which it was completed, but also for the fulness with which the system it presents was elaborated at the work's first appearance in 1536. For though revised and extended, more logically and inclusively presented, in the edition of 1539, still further revised in 1543 and 1550, and reaching its final form only in 1559, it shows throughout no sign of change of position, still less of retraction. Begun in 1534 when Calvin was barely 25, the book was practically completed when in August, 1535, Calvin addressed the remarkable letter to King Francis I, with which it opens. As this letter shows, the Institutes were composed, or at least completed, to meet a present necessity, to correct an aspersion on his fellow reformers. The French king, wishing to suppress the Reformation at home yet unwilling to alienate the reforming princes of Germany, had sought to confound the teachings of the French reformers with the attacks of Anabaptists on civil authority. "My reasons for publishing the Institutes," Calvin wrote in 1557, "were first that I might vindicate from unjust affront my brethren whose death was precious in the sight of the Lord, and next that some sorrow and anxiety should move foreign people, since the same sufferings threaten many." Therefore he wrote in Latin, but he proceeded immediately to translate his work into French, and in both forms it gained quickly wide circulation.

"The hinges on which our controversy turns," says Calvin in his letter to the king, "are that the Church may exist without any apparent form" and that its marks are "pure preaching of the word of God and rightful administration of the sacraments." If such preaching bring disorder, the blame is not with it but with Satan. The 'Institutes,' in this first form, follow the traditional arrangement, observed also in Luther's short catechism of 1529, and fall into six chapters. The first three, dealing with Law, Faith, and Prayer, and, in the main, the fourth, treating of the sacraments of Baptism and the Lord's Supper, are expository. The last two were of necessity more controversial, for they dealt with "False Sacraments," namely Confirmation, Penance, Unction, Orders, and Matrimony, and with Christian Liberty, Ecclesiastical Power, and Civil Administration. The controversial tone, even here, is, however, less pronounced than in later revisions, and what are commonly regarded as the distinctive features of Calvinism are less emphasized.

The 'Institutes' in this first form were not merely a logical and felicitous exposition of Reformation doctrine; they proved the inspiration to a new form of Christian life. Their debt to Luther in the treatment of Faith and Sacraments, to Martin Bucer in what is said of Divine Will and Predestination, and to the later scholastics for teaching involving unsuspected implications of freedom in the relation of Church and State, has been clearly traced. Yet the 'Institutes' were justly felt to be as a new voice, and before the year was out there was demand for a second edition. This came in 1539, amplifying especially the treatment of the Fall of Man, of Election, and of Reprobation, as well as that of the Authority of Scripture. It showed also a more irenic temper toward Luther in the section on the Lord's Supper. The edition of 1559, claiming to be

"almost a new work" is in fact a complete recasting of the old 'Institutes' into four books and 80 chapters, on the basis of the Apostles' Creed. In this form the work was translated into French and Dutch in 1560, into English in 1561, into German in 1572, into Spanish in 1597. Seven other editions and four abridgments appeared in English before the end of the 16th century. A judicious summary of the teachings of the 'Institutes' is to be found in W. Walker's 'John Calvin,' pp. 409–429. No book of its century showed such power to spread ideas and to unify the strivings for reform. That cardinal period in Christian development found in this book the most logical, clear, characteristic presentation of what reformers prized as truth, and, though its teachings are nowhere held to-day in their fulness, the place of the 'Institutes' as a Christian classic is secure.

Very important in their apparently unrealized implications were the teachings of the 'Institutes' on civil government. They counted it the function of an ideal state to see that no "offenses against religion break out or be disseminated." It was, indeed, a duty to submit to rulers negligent in this regard; but "if they command anything against God, let us not," says Calvin, "pay the least regard to it nor be moved by all the dignity which they possess as civil magistrates" ('Institutes,' IV, xx, 32). With the example of church officers responsible to the congregations they served, such teaching could not fail to stimulate the movement toward individual liberty and democratic freedom.

Changes from the teaching of the 'Institutes' among those who most cherish Calvin's memory are notable in the matter of church discipline and in regard to the duty of civic rulers to guard the purity of the church. Changes are seen also in the doctrine of the Scripture, of election, reprobation and human depravity. This is natural. The appeal of the 'Institutes' was to the intellect, and these very changes are in large part the result of the vigorous thinking which the 'Institutes' demanded and of which they were so eminent an exemplar. The standard edition of the 'Institutio' is in Calvin's Works, edited by Baum, Cunitz and others (59 vols., Brunswick, 1863–1900); the last volume has a full bibliography. Translations by H. Beveridge (3 vols., Edinburgh, 1845–46) and others. See Rayburn, H. Y., 'John Calvin, his Life and Works' (New York 1914); Penning, L., 'Life and Times of John Calvin' (New York 1912); Walker, W., 'John Calvin' (New York 1906).

BENJAMIN W. WELLS.

INSTITUTES OF ORATORY, The ('De institutione oratoria'), of Quintilian, composed after his retirement from active life, took more than two years to write (89–91), but was withheld for a few years until the urging of his friends compelled its publication, the circumstances of which are given in a foreword addressed to his publisher, the bookseller Trypho. The work itself, consisting of 12 books and dealing with the whole education of the future orator, was dedicated to Vitorius Marcellus (the same to whom Statius addressed the fourth book of his 'Silvae'), whose son Geta showed talent. Quintilian probably also had in mind his own elder son. He repeatedly attacks the ordinary handbooks of rhetoric, while his own theory is based on his own experience and the best views of different authorities, especially Dionysius of Halicarnassus, Cæcilius, Chrysippus, Cicero (upon whom his exposition is mainly founded and from whom he seldom differs and then only with reluctance), Cornificius and Celsus. Quintilian insists that the orator must be of good moral character as well as versed in rhetorical accomplishments. His illustrations are drawn mainly from the classical writers and he attacks the style of his own day, at the same time warning the pupils also against the early writers. Especially interesting is the 10th book, which treats of literary criticism as regards the Latin and Greek prose writers and poets useful to the orator. The chief manuscripts of the 'Institutiones' date from the 10th and 11th centuries. A large and annotated edition is that of G. L. Spalding (Vols. I–IV, Leipzig 1798–1816), C. G. Zumpt (Vol. V, 1829) and E. Bonnell (Vol. VI, containing lexicon and indices, 1834), but the pincipal edition is that of C. Halm (Leipzig 1868), revised by F. Meister (Prague 1886–87). Book X has been separately edited by J. E. B. Mayor (pt. I, London 1872), E. Bonnell and F. Meister (5th ed., Berlin 1882), G. T. A. Krüger and G. Krüger (3d ed., Leipzig 1888) and W. Peterson (Oxford 1891). The 'Institutiones' have been translated several times into several of the continental languages and an English translation by J. S. Watson (2 vols., London 1902–03), with notes based on Spalding, appears in the 'Bohn Classical Library'.

HERBERT F. WRIGHT.

INSTITUTIONAL CARE OF THE INSANE. See INSANE, INSTITUTIONAL CARE OF.

INSTITUTIONAL CHURCH, a noncredal organization of Christians, to supplement the regular church methods and ministrations — preaching, prayer-meetings, Sunday school, and pastoral visitations — by helpful social work in the community. The moving spirit is the same as in the Y. M. C. A., University Settlement, Salvation Army, Rescue Missions, Christian Endeavor societies, etc.; but "with the emphasis on Church, not Institution." The prime object is to reannex to the church the functions which other bodies have been compelled to fill by its neglect of its duty; and strengthen it by gathering potential Christian elements which under the old system do not come to it, as well as by combining in itself all the claims to public gratitude and interest now shared between the purely ecclesiastical and the purely social institutions, or the halfway houses like the Y. M. C. A. It differs from the latter in not merely furnishing a religious atmosphere which may lead to church membership, but enrolling members at once in a real church of Christian work by absorbing the secular features of the other; in a word, to do, without vows or uniforms, what the Catholic Church has always done with its charitable functions — make them an integral portion of the church organization. Hence, it is not by itself a church in the sense of the Roman Catholic or the Methodist Church, but in a broad sense a description of any church which adds educational or social work; in general use, a title of any which throws into this work its predominant vitality. Free pews are an es-

sential accompaniment, as the social aristocracy fostered by rented pews contradicts the basal democratic principle of institutional work; hence it is sometimes called Free Church, but preferably Open Church. The present name originated with President Tucker of Dartmouth College, who applied it to Berkeley Temple, Boston.

The movement started chiefly with the High Church element in England, modeled on the Catholic idea; it flourished for two generations in that country before reaching the United States, about 1880. Now a large number of churches — Episcopal, Congregational and Baptist in the forefront, but also Methodist, Presbyterian, Unitarian — have adopted the idea with increasing vigor, besides the work of this class always performed by the brotherhoods and sisterhoods of the Roman Catholic Church. One of the earliest of these was Plymouth Church of Indianapolis, inspired by the memory of Mr. Beecher. Notable among others are the Saint Bartholomew, Saint George, Saint Paul and Judson Memorial of New York, and the Tabernacle of Jersey City; Berkeley Temple, Parker Memorial, and Ruggles Street Baptist of Boston; Grace and Bethany of Philadelphia; Ninth Street of Cincinnati, Pilgrim of Cleveland; Plymouth Tabernacle of Detroit; People's of Saint Paul; and the Denver Tabernacle. In 1894 the Open and Institutional Church League was organized in New York; it held several conventions in Eastern cities (1895–1901), and for three years published the 'Open Church' as its organ, but has practically lapsed, being merged in the 'National Federation of Churches and Christian Workers.' The total of its work, however, is not shown by its nominal membership; the same spirit has infected outside churches, and their methods are being more and more adopted as a general basis of work.

The platform of the League stated that it aimed to save all men by "abolishing, so far as possible, the distinction between the religious and the secular"; by "open church doors for every day and all the day, free seats, a plurality of Christian workers, the personal activity of all church members, a ministry to all the community through educational, reformatory and philanthropic channels, to the end that men may be won to Christ and his service, that the Church may be brought back to the simplicity and comprehensiveness of its primitive life." It is not correct to say, as is often done, that its methods are purely secular: its *additional* methods beyond the regular religious ones are so, for the very reason it exists. These involve a thorough organization for social and philanthropic work; but the religious features are sedulously conserved and carefully fitted to the work, the spirit of worship being cherished and made the centre of inspiration. The service generally ends in the communion; there is congregational singing of both hymns and chants, led by a highly trained choir, and often responsive readings; the whole with the sermon are intended to be brief, varied, and attractive. Sunday schools are carefully attended to; prayer meetings given new features; in summer there are open-air meetings; and other Christian associations, endeavor societies, brotherhoods, etc., are encouraged. The officers and workers of the church are given active special duties, such as pastoral visiting, reception and welcome of strangers, canvassing for the various activities of the church; and there are not only sub-pastors, but deaconesses, sisters and nurses. The purely secular side embraces all departments of culture, physical, intellectual and moral, as well as direct charities. Morally, the church work above should be sufficient. The charitable departments include not only direct aid to the poor, but wood-yards, employment bureaus, etc.; personal endeavor to provide employment for those willing to work; dispensaries, hospitals and crèches; and encouragement to thrift by savings funds. Special buildings are often erected.

That the movement is liable to perversions is admitted; such is the case with every institution. Secularization is one; but unless it can be faced, the churches cannot influence or draw in those outside them, for the simple reason that the latter cannot be brought within hearing. Sensationalism, to draw in hearers to be benefited, is a graver one, and ill-judged; as one of its chief workers puts it, "a camp-stool congregation neither pays nor repents," and a lasting work must be content with slower processes. Consult Burr, A. R., 'Russell H. Conwell, Founder of Institutional Church in America' (Philadelphia 1905); Forbes, J., 'Social Ideas of a Free Church' (Boston 1913); Thwing, C. F., 'The Working Church' (New York 1913).

INSTITUTO HISTORICO E GEOGRAPHICO BRAZILEIRO (Brazilian Historical and Geographical Institution), a Brazilian society devoted to the advancement of historical and geographical knowledge, founded at Rio de Janeiro in 1839. Under its auspices and with its aid many historic documents relating to the early history of Brazil have been printed and thus made available to historical students throughout the world. The society publishes many such documents, also accounts of geographical explorations, etc., in its periodical *A Revista Trimensal.*

INSTRUMENT, *in law,* a written document evidencing an agreement or acknowledging a claim, as a deed, grant or will. The term has been held to mean also, in its widest sense, any written document, as a statute or record, but scarcely to apply to accounts, memoranda, or ordinary letters.

INSTRUMENT OF GOVERNMENT, the written constitution under which Oliver Cromwell governed Great Britain and Ireland from 16 Dec. 1653 to May 1657. It consisted of 42 articles, and vested the legislative power in the hands of "one person and the people assembled in parliament." The executive power was placed in the hands of Cromwell as Lord Protector of the Commonwealth; his office was made elective and he was to be assisted as executive by a council of state of from 13 to 21 members. Councilors were appointed for life. A new parliament was to be called every third year, and a parliament could not be dissolved in less than five months except at its own request. There were 460 members in the single chamber — 400 for England and Wales and 30 each for Ireland and Scotland. The distribution of seats was altered. A property qualification of £200 was placed on voters.

Roman Catholics and those who had opposed parliament during the Rebellion were disfranchised. This constitution contained several elements of weakness and its downfall was assured as soon as it dared assert its independence of or opposed the Lord Protector. Consult Gardiner, 'Constitutional Documents' (Oxford 1889; and Jenks, 'Constitutional Experiments' (London 1891).

INSTRUMENTAL MUSIC. See Music; Musical Instruments; Orchestral Music.

INSTRUMENTALISM, in philosophy, a system, akin to pragmatism, according to which thought is considered an organic function, the object of which is to maintain the even tenor of experience, restoring the latter when it is interrupted or confronted by a special situation. See Epistemology; Pragmatism.

INSTRUMENTATION, in music, the arranging of music for a combined number of instruments. The nature and character of the musical ideas must determine whether the instrumentation shall be simple or artistic, and perhaps complex; the latter being the case when some of the instruments take a more prominent part than others. For both purposes, a thorough knowledge of every instrument in the orchestra is absolutely necessary, as without this instrumentation becomes only a deafening mass of sounds. The stringed instruments, from their nature, in most cases, form the principal parts of a score, around which the other instruments move, without depriving them of their importance. The wind instruments represent, more or less, a subordinate chorus, which may again be divided into two kinds, viz., the wood instrument and the brass, which, with the stringed instruments, give three essentially different choral effects, that may be mixed together in endless variety. A knowledge of the art of instrumentation is acquired only by great experience; at the same time much may be learned by consulting the best works on the subject such as Sundelin, 'Die Instrumentirung für das Orchestra'; Berlioz, 'Traité d' Instrumentation'; Gassner, 'Partiturkenntniss.'

INSTRUMENTS, Engineering. See Engineering Instruments.

INSTRUMENTS, Musical. See Musical Instruments.

INSUBRES, a Celtic people of northern Italy. In the 4th century B.C. they settled in the region between the Alps and the Apennines. They were frequently at war with the Romans after 222 B.C., and in 194 their capital Mediolanum (Milan) was taken and they were finally brought under the yoke of Rome. Consult Holder, A., 'Altkeltischer Sprachschatz' (Vol. II, 1904).

INSULAR CASES, a series of legislative problems created by the "accretion" to the United States of insular possessions following the Spanish-American War in 1898. They arose over President McKinley's recommendation in his message on the convening of the 56th Congress, 3 Dec. 1899, that "legislation should be enacted establishing a civil government in Porto Rico," and involved the status of the citizens of our insular possessions and the constitutionality of an intra-national revenue tax. The Foraker Act, 11 April 1900, defined the relation of the island to the United States, by placing it on a status outside of the Constitution and also outlined a scheme for the government of dependencies that obligated the nation to a new and united policy. This gave rise to the Insular Cases which debated the question of the right to demand duty for commercial articles imported into the United States from Porto Rico. On appeal the Supreme Court decided that the insular possessions were obtained under the clause regulating the making of treaties, and "that the power to acquire territory by treaty implies not only the power to govern such territory, but to prescribe upon what terms the United States will receive its inhabitants, and what their status shall be." See Porto Rico; Cuba; Hawaii; Philippine Islands.

INSULATION, non-vibrating or non-conducting material designed to cut off or check the spread of some form of vibration, as heat, sound, electricity, etc., also the process or act of surrounding a body with such non-conductors. The term is sometimes extended to cover insulating material. For shutting out sounds and for keeping in heat, a closed air-space is a simple and effective medium. It is made use of in house-walls, thermos bottles and in refrigerating appliances. For insulating a boiler asbestos or mineral wool is commonly employed, because it will bear the heat. To resist the passage of electricity, glass, shellac, resins, sulphur, ebonite, paper, lead, gutta-percha, silk and baked wood are notable insulating materials. To prevent the lateral passage of electricity from one wire coil to another the wires are usually covered with silk and shellac. See Electricity, *Conductors and Insulators.*

INSULIN, a ferment isolated from the smaller glands of the pancreas (the Islands of Langerhans) and used in the treatment of diabetes. It was first isolated by Dr. F. G. Banting, of the University of Toronto, announcement of its isolation being made in 1922. Its use re-establishes the metabolism of sugar in diabetics.

INSURANCE, a contract by which one party, for a stipulated consideration, undertakes to indemnify or compensate another party against loss by certain specified risks. The party undertaking to make the indemnity is usually called the insurer or underwriter, the other the insured or assured; the agreed consideration is termed the premium; the written contract, a policy; the events or causes of loss insured against, risks of perils; and the thing insured or the subject to be protected, the insurable interest. Marine insurance relates to property and risks at sea; insurance of property on shore against fire is called fire insurance; life insurance, in its widest sense, is a contract entered into by the insurer to pay a certain benefit contingent upon the duration of one or more lives. Besides these classes of insurance there are many others; the traveler may insure himself against loss entailed from damage by rail or sea; the farmer from the inroads of disease among his live stock; the employer from the fraud of a dishonest cashier, etc.

The practice of marine insurance seems to have long preceded insurances against fire and upon lives. It is impossible to state the precise period of its introduction, but it is probable that it dates from about the beginning of the 15th

century; though it is contended, on the authority of certain ancient writers, that traces of this form of insurance are to be found among the Romans. Some Anglo-Saxon guilds insured their members against loss from fire, water, robbery, etc. Commercial insurance, however, seems to have originated in Flanders about 1300, although priority is claimed for both Italy and Spain. It is probable that insurance was introduced into England by the Lombards early in the 16th century, but few court cases pertaining to it are found till the middle of the 18th century.

In Great Britain fire insurance has been practised for over two centuries, but on the Continent its introduction dates considerably later. The history of life insurance, as well as that of various other forms now in practice belongs to a still later time. For the history and development of the principal insurance systems in America, see ACCIDENT INSURANCE; AUTOMOBILE INSURANCE; BURGLARY INSURANCE; COMMERCIAL LIFE INSURANCE; GROUP INSURANCE; HEALTH INSURANCE; INSURANCE, INDUSTRIAL; INSURANCE, LIFE; INSURANCE, LIFE, STATISTICS; INSURANCE, MARINE; INSURANCE, SCIENCE AND ECONOMICS OF; INSURANCE LAW; INSURANCE SUPERVISION; INSURANCE FRATERNAL; OLD AGE INSURANCE AND PENSIONS; SOCIAL INSURANCE; WORKMEN'S COMPENSATION, etc.

INSURANCE, Credit. This is a contract issued to jobbers, manufacturers and wholesale dealers guaranteeing indemnity for losses sustained through insolvent debtors in excess of their normal trade loss as shown by the insured's records or as agreed with the insurer. Such a policy commonly runs from year to year and covers only such sales of merchandise as are shipped and delivered.

Credit insurance was first authorized by statute in New York in 1886, in New Jersey in 1889 and in other States shortly after these dates. The first company to undertake such risks in America was organized in New Jersey in 1888 under the title United States Credit System Insurance Company. Other special corporations of this character followed, in Louisiana in 1891, in New York in 1892 and in Minnesota in 1893. The field being new, these earlier ventures suffered from lack of experience on which to base the business and all but one came to an end within a few years. The general casualty corporations, already assuming varied lines of this character, were shortly qualified to assume credit risks, but the field has been left so far to a few companies which perform an increasingly useful function for the greatly expanded business credit system of the present time. The business is handled almost entirely by one New York company and the United States branches of two foreign companies.

The plan of operation for credit insurance was devised by the actuary of the first company organized and has been followed by its successors, experience affecting mainly the matter of rates and the selection of risks.

The basis of the whole scheme of this class of insurance is the generally accepted mercantile ratings, as evidencing the financial strength and reliability of the debtors concerned. The insurer, however, undertakes to give indemnity for only the excess of credit losses beyond the ordinary percentage experienced by the insured's business, not including single sales or transactions but the average loss sustained during not less than one year.

This insurance is not only confined to risks on parties having mercantile ratings, but the amount of sales covered is limited to a percentage of a debtor's lowest capital rating as given by mercantile agencies. A policy may be had to apply to debtors of the first and second grade commercial ratings, or for a larger premium the policy will cover in addition parties with lower ratings.

Credit policies state minutely the conditions of the contract and define liberally when a condition of solvency exists and in what manner a claim shall be set up. Reckless management combined with inexperience to demoralize the business during the earlier years, and technical defenses were often resorted to as an offset to claims. In later years credit insurance became settled on stable and conservative lines and has prospered. The passage of a general bankruptcy act by the federal government in 1898 materially aided in placing credit insurance business on solid ground.

The table here given sums up the results of all this class of business transacted in America as far as reported in the best authorities, showing the early period of uncertainty separately, then the five-year periods to the end of 1916, and lastly the year 1917 by itself.

CREDIT INSURANCE IN AMERICA.

	Premiums	Losses	Ratio per cent.
1889–1896	$2,297,917	$1,174,491	51.1
1897–1901	$2,543,296	$656,259	25.8
1902–1906	9,867,731	4,258,707	43.1
1907–1911	9,835,400	6,446,803	65.5
1912–1916	7,405,227	4,084,458	51.1
Total, 20 years	$29,651,654	$15,446,227	52.1
1912	$1,611,352	$1,195,839	74.2
1913	1,496,826	923,292	51.7
1914	1,487,506	732,139	49.2
1915	1,395,713	939,765	67.3
1916	1,413,830	293,423	20.7
1917	$1,665,915	$96,676	5.8

The table shows that, when trade conditions were normal, premiums were sufficient to pay losses and leave an ample margin for expenses and profits, but that during times of stringency and emergency, as in 1907 and 1914, greatly increased losses followed. This dangerous uncertainty can be met only by an ample surplus accumulated out of the years of plenty for the years of leanness that are sure to recur, whether caused by crop failure, financial disturbance, contagion, war or abrupt economic changes, as it is precisely against such surprise contingencies that credit insurance must demonstrate its highest utility.

From the statement of an official long experienced in this line of protection, the benefits of credit insurance may be summarized as follows:

It serves as a reserve to the insured's capital, equal to face of the policy, to offset unexpected losses.

It serves as collateral security to accounts against misfortunes that may befall even preferred customers.

It protects profits against unexpected and unavoidable losses.

Joined with the other forms of insurance it completes the chain of commercial protection.

It is readily seen that the function of credit insurance is that of all insurance — not to relieve the creditor of responsibility for his accounts or to invite debtors to repudiate their honest indebtedness, but to provide against those uncertain and unforeseeable events which commercially embarrass the latter and jeopardize the enterprise of the former. By a properly conducted credit insurance such losses are widely distributed among creditors in similar business circumstances, so that no one is seriously burdened.

CHARLES MAAR,
Insurance Department, State of New York.

INSURANCE, Fraternal. This term applies to a large class of societies that has come into existence in America since the Civil War, whose primary object is to provide a substantial death benefit for the families or dependents of the members on the co-operative plan. These orders are to be distinguished from the older class of secret societies, comprising the Masons, Odd Fellows and Foresters, which originated for the most part in Europe and have primarily social and benevolent objects; and also from another large class of societies that has come into being during the past half century or more and which combine good-fellowship with stipulated sick and funeral benefits, although some of the first-named orders afford sick or other benefits, in one way or another, in addition to death benefits.

It is well known that all fraternal societies, as known in America and now numbering many hundreds, have distinctly moral and religious foundations, are educational and tend to develop character, good citizenship and the spirit of co-operation and mutual helpfulness. The Masonic bodies afford charitable relief generously where the need is made evident, but in other fraternities the kind and measure of the benefits are stipulated and become the right of members on the basis of their dues or assessments and good standing, irrespective of a necessitous condition.

History.— Mutual benefit societies for one object or another are found back as far as the dawn of history. Whatever was necessary or desirable to people in common might be secured by co-operation when the chances of life or the hazards of death rendered the individual helpless. Burial societies were common among the Greeks and Romans, because ceremonial sepulture was indispensable to the repose of the spirit in the land of shadows — the underworld. Among the Teutonic nations, guilds flourished not only for relief against misfortune but for co-operation and protection in daily affairs.

From its earliest rise in Europe the Christian Church was a centre of charitable relief to all whom its benevolent activities could reach. Not only the teaching of its founder, but its own hard early experiences, emphasized charity as the highest of the graces of human character. In Great Britain the system of Church relief was swept away in the general seizure of endowments under the reformation enforced by Henry VIII and in its place under Elizabeth was substituted a system of public relief by poor-rates which has continued with changes to the present time. The old guild spirit, however, came to the surface again during the reign of Charles I, although the guilds had gradually fallen into decay during and after the Elizabethan period. The result was the rise of the English friendly societies for co-operation among people in moderate circumstances who were not satisfied to fall back upon the tender mercies of the poor-rates but endeavored in a self-respecting way to forefend the ills of life and the mischances of affairs by provisions for sharing the hazards among themselves — a principle that is at the bottom of all modern insurance.

Little or no historic connection is apparent between the guilds or friendly societies of Great Britain and the fraternal beneficiary orders of America. The latter clearly took their rise out of the new social and co-operative spirit that was developed by the Civil War, which drew together for the first time on this continent millions of people in a vast undertaking, and by the very necessities of the task drew forth and trained their faculties for joint action to a degree there had not been occasion for before. The pioneer period of America called for the individual hardihood and personal self-reliance that subdued a broad continent and carried settlements from coast to coast. The Civil War indicated an excess of individualism, or at least the approach of a new era which called for an abundant measure of unselfish social co-operation to save the nation from futile division and the continent from antagonistic civilizations.

Between the time of the Revolution and the Civil War such fraternities as the Odd Fellows and the Ancient Order of Foresters and the Ancient Order of Hibernians had been transplanted to America from Great Britain, and certain native societies, like the Tammany Society, the Red Men, the United American Mechanics, the Good Templars, Sons of Temperance, and a number of others with clear political or moral objects, had come into existence, all of which afforded a measure of charitable relief to their members; but the credit is accorded to John Jordan Upchurch, the founder of the Ancient Order of the United Workmen, at Meadville, Pa., in 1868, for the initiation of the movement toward the organization of a new class of fraternal orders that was to make the provision of a substantial death benefit their primary object. Upchurch's effort was linked with a desire to bring together in relations of mutual help and good understanding the large group of workers that the rapid expansion of manufacturing industry during the Civil War had centred in many of the American cities. He sought to meliorate trade troubles the while joining the new craftsmen in an effort for self-help, socially and intellectually, and against the one greatest certainty and uncertainty of life, to wit, the contingency of death, which was apt to leave the worker's dependents helpless in a strange place away from even the meagre living that the widow and orphan could find in village and rural communities.

Characteristics.— In each decade since the close of the Civil War period scores of new fraternal benefit orders have been formed, with differing plans of operation but with the same general character. Some have been spurious and sought to make fraternalism a source of private profit. Many have remained local in-

stitutions, while many others have become general and have extended over the United States and Canada. A number are sectarian or racial in their constituencies, being confined to Protestants, Catholics or Hebrews. To most of the orders men alone are eligible; yet not a few are open to both sexes and a few are purely women's societies. Some of the earlier moral or political orders have in the interval since organization adopted a plan of death benefits, and most of the later organized trade unions have such a benefit. The genuine fraternal benefit orders use the lodge system, with the social and moral influence of its ritual and form of initiation and its fraternal bond, to carry out the object of co-operative insurance.

The earliest orders, in addition to certain moral and physical tests, called for a uniform contribution from each member to meet benefit claims as these arose. This was pure charity in essence if not in form and left the future utterly without provision, under the assumption that there would always be members enough and willing to meet demands on call. The United Workmen in particular was organized under independent State jurisdiction. This proved a source of weakness to the order and disclosed the insufficiency of its financial plan sooner than with others which began with a general jurisdiction and so had the younger lodges to share the inevitably increasing claims of the older.

At this period scientific practice of life insurance had not yet been fully worked out and such business corporations as were operating in America did not cater to the man in moderate circumstances, whereas the lodge appealed to him and met his needs for social sympathy and relaxation and for a warm helping hand in emergency, especially in our migratory American life. The movement toward fraternal insurance was strongly accelerated during the decade following the panic of 1872 by the failure of a large number of business companies that were insecurely organized or badly managed.

Learning from experience that was sometimes costly, even as the business corporations before them, the fraternal benefit orders soon passed from the first crude idea of a uniform contribution and came to depend on a closer medical selection and a contribution graded according to the member's age at entry; but even so they fell short of a condition essential to permanence in not realizing that sufficient income must be had for both current needs and for a reserve accumulation to meet future obligations, since under a purely mutual scheme the members who pass away first must contribute to not only their own but to the benefits of those who pass away later.

Doubtless a better understanding with the students and leaders of actuarial science would have saved much confusion and loss, but fraternal leaders in the end have profited by their experiences and the fraternal orders have been an acknowledged educational influence that has made America of to-day the best insured portion of the world. A table of mortality built upon fraternal experience, adopted in 1899, has become a standard for rates and since that date a continuous effort has been made to bring fraternal insurance to a scientific basis.

Development.—Looking back over the less than 50 years of fraternal insurance, a steady improvement in plans and methods is to be noted, as well as an amazing expansion of the idea, as shown in the accompanying table. Ignorance and error may be freely acknowledged, but none the less it was an altogether natural event and thrilling now to contemplate that the great democracy of the West, after gaining a new consciousness of solidarity from four years of civil strife, should launch on a great co-operative effort touching that event of life which deprives the great majority of families of their chief support.

To the splendid record of financial benefits provided, hundreds of thousands of families that would otherwise have been left nearly destitute, must be added the incalculable moral, social and educational influence the lodges have had upon American life during the past half-century. The benefit orders are a true expression of democracy and a fruit of the self-respect and self-reliance for which popular self-government stands.

Owing to the insecurity of the earlier plans and in some cases to poor business methods numbers of benefit orders have come to grief, while others have found it advantageous to amalgamate. Those that have wisely forestalled trouble by increasing rates and bettering methods, and the younger orders that profited by the experiences of predecessors in the field, have entered upon a new era of development which will be marked, not so much by large numbers as by strength and quality.

The nearly two decades of the 20th century have been troublous for the fraternal orders owing to the agitation and uncertainty attending discussion of rate changes and the elimination of the endowment or short-term certificate, which latter proved as deceptive as the tontine forms of old-line policies and is no longer offered by any reputable society; yet according to the completest showing available, that of the 'Spectator Year-Book,' the following table represents conditions on Jan. 1, 1917:

SUMMARY OF 560 FRATERNAL ORDERS OF UNITED STATES AND CANADA AT THE CLOSE OF 1916

Certificates in force 1 Jan. 1917	9,191,860
Number of lodges	124,912
Income for 1916	$178,867,638
Disbursements	141,280,882
Claims paid	116,769,888
New insurance written	1,182,642,577
Assets 1 Jan. 1917	319,392,839
Liabilities	81,846,123

RESULTS OF 180 OF THE LEADING ORDERS AT THE CLOSE OF 1917

Net gain in certificates	168,904
Benefits paid, 1917	$113,763,279
Total insurance in force	9,634,662,126
Assets 1 Jan. 1918	344,618,330
Liabilities	*84,116,631

* Includes $62,529,414 reserves.

About 100 minor orders are not included in this tabulation. Of the 560 societies included, 380 have $1,000,000 or over of insurance in force. A compilation made by another reliable authority, the *Fraternal Monitor*, gives the aggregation of death benefits paid since organization by American benefit societies, to the end of 1917, as $2,344,738,818. The amount of sick, hospital and funeral benefits paid by local lodges is not available but the aggregate of such benefits paid by the larger benevolent orders offering them is $624,866,506.

The fraternal beneficiary orders have in recent years had a yearly addition of 1,000,000 new members, the yearly payment of over $100,000,000 in death benefits, the yearly increase of over $1,000,000,000 in insurance in force, and a substantial increase in assets over immediate liabilities.

Some of the larger orders have latterly provided old age and disability benefits and many of the local lodges have from the first had in operation special sick, hospital and funeral benefits for such of the membership as wish to share them.

New Standards Set.—A long and definite advance in fraternal history was registered in 1886, when, pursuant to a call fathered by the Supreme Lodge of United Workmen, 16 of the leading orders met at Washington, D. C., and formed a federation, entitled the National Fraternal Congress, with which others soon affiliated. In 1901 a number of orders formed a separate organization, the Associated Fraternities of America. The two bodies, by means of yearly gatherings and discussion, proved a good influence in setting standards and developing uniform and business-like methods.

The efforts of these federations, not always harmonious at first, at length made for unity of purpose and brought them to actual unity in 1913. The results of many years of experience, criticism and agitation found fruition in 1910, under the guidance of the National Convention of Insurance Commissioners held at Mobile, Ala., in a model fraternal code, which was slightly modified in 1912 at New York. This so-called Mobile bill, or the later New York Conference bill, was promptly enacted into law by a number of States, and now controls in 37.

During the years when the necessity for more adequate rates was becoming apparent, as some orders made provision for an increase rather than resort to more than the monthly calls that had come to prevail, their action was contested by individuals in a number of cases. The State courts in Iowa, New Jersey and New York rendered decisions adverse to the right of particular orders to adjust their rates, while Connecticut and Texas rendered favorable decisions. A case was in due course carried up to the United States Supreme Court, which in 1916, in Green *v.* The Royal Arcanum, gave decision at the hands of Justice Hughes practically securing this right to the orders on the ground that a benefit certificate is not a mere business contract but an agreement among the holders for no other consideration than that mutually provided and which all were bound to make good.

By means of the uniform code the characteristic features of fraternal benefit orders are now written into statute law generally as societies having a lodge system, with ritualistic form of work and a representative form of government and making provision for mortuary benefits, to which may be added benefits in case of sickness, accident and old age, providing disability benefits do not begin under the age of 70. Besides provisions for the more responsible conduct of their business and a closer public supervision, the uniform law provides for a standard of valuation to be used from 1917 and to which each order must attain by progressive improvement, or else by the end of three years adopt increased rates for new members and hold the funds for such members in a separate class.

Whole Family Protection.—A new development in fraternal circles is a plan for extending fraternal insurance to the minor children of members. The orders have hitherto allowed membership of one or both parents and of minors at the age of 18. The States of Connecticut, Iowa, Kansas, Maine, Massachusetts, Michigan, Missouri, Nebraska, New Hampshire, New York, North Carolina, Ohio, Oklahoma, Oregon, Rhode Island, Texas, Utah and Wisconsin had by the first part of 1918 provided for the insurance of the children of members of fraternal orders. A uniform bill for whole family protection, adopted by the National Convention of Insurance Commissioners in 1916, has been followed in general. The plan of the industrial companies is used with a separation of funds in a juvenile department. Whole family protection is in wide use among the friendly societies of Great Britain.

INSURANCE, Health. See HEALTH INSURANCE.

INSURANCE, Industrial. Industrial insurance may be defined as retail family insurance. While in scientific principles it does not differ at all from ordinary life, or "annual premium," insurance, in practice its distinctive features are: (1) That instead of having its policies written for $1,000 and multiples thereof at varying premiums according to mortality tables, its policies call for premiums of five cents, or some similar unit, and multiples thereof, the amounts of insurance varying according to age; (2) the premiums, instead of being payable annually, or semi-annually, or quarterly, are payable weekly; (3) these premiums are called for weekly by collectors, instead of being remitted by mail; (4) the amounts of insurance payable are based upon mortality tables drawn from experience in industrial insurance, and these tables differ very widely from the tables used by the ordinary companies; (5) the insurance is taken upon lives between ages 1 and 65, without distinction as to sex. Industrial insurance is so called because it is the insurance of the working classes, and for this reason it has grown very rapidly.

History.—For its origin industrial insurance must point to the guilds of the Middle Ages, whose place was taken in England, after the Reformation, by burial societies or clubs. These were voluntary associations, meeting periodically and collecting dues and undertaking to bury members out of the fund so paid in. The dues were the same for all ages, and the management was so bad that up to 1867 about 14,000 of the clubs out of 38,000 had collapsed and a large majority of the existing remainder were insolvent. In 1849 the first industrial life

insurance company was founded in England, called the Industrial and General; three years later an offshoot, called the British Industry Life Insurance Company, was formed; two years after this, in 1854, the Prudential Assurance Company, which had been in existence six years as an ordinary company, took up the industrial business and soon absorbed the British Industry. At the outset the business was experimental, as actuaries had insufficient data upon which to base calculations; and several tables of benefits for the weekly premium of a penny succeeded each other, widely differing in amount. The first table ran from ages 10 to 50; age 10 was found too high for practical working and the table was run down to age 7; then a demand arose from the people for insurance at younger ages, which was first met privately by an agent of the Prudential on his own account. His fine business record attracted the attention of the officers, who found it arose from his practice of himself insuring the younger members of the family. This discovery led to the company's making its system a real family insurance. It was not successful until all ages were accepted. Therefore the business grew rapidly, so that at the end of 1917 the Prudential had 21,730,468 industrial policies in force, secured by £53,602,348 of assets credited to the Industrial Branch, besides £53,642,748 assets credited to the Ordinary Branch. The Board of Trade exhibit of regular industrial insurance (that is, excluding friendly societies) in Great Britain shows the steady and rapid growth of the business, as will be seen from the following table:

INDUSTRIAL INSURANCE IN GREAT BRITAIN.

YEAR	Number of companies	Number of policies in force	Insurance in force
1890	8	9,432,778	£86,203,873
1900	14	18,653,846	181,135,538
1910	14	29,149,924	292,689,157
1915*	19	38,004,956	433,900,645

* During the progress of the war these tabulations were discontinued.

The number of policies in force in the industrial companies of Great Britain exceeds four-fifths of the population of the country.

In America the first weekly premium experiment of importance was the connection of the Hildise Bund, a society which received premiums weekly and used them to pay to the Metropolitan Life Insurance Company to be credited upon quarterly premiums on policies issued by the company on the lives of the members of the Bund. A large business was done on this plan for several years after 1869, amounting at one time to $7,500 per week. There were other similar societies in name, but they seem not to have done much business. The English experiment had attracted a good deal of attention in America, and various industrial insurance companies were formed which, however, never got to the point of issuing policies. There was a good deal of literary discussion which culminated in a state report in 1874 by Commissioner Clarke of the Massachusetts Insurance Department, describing the work of the English Prudential Company and setting forth the principles of industrial insurance. In 1875 the Prudential Insurance Company of America, then a small corporation in Newark, N. J., known as the Widows' and Orphans' Friendly Society, changed its name to the Prudential Friendly Society and in November began the industrial business on the lines of the London company, after which it was named. Before it attained much growth the John Hancock Mutual Life Insurance Company of Boston, the Germania Life Insurance Company of New York (which, however, soon ceased writing industrial insurance), and the Metropolitan Life Insurance Company of New York, old line companies of experience, began the industrial business. The progress of this system of insurance in the United States has been wonderful. Its first policy was issued in America only 43 years ago; at the end of 1918 there were in force in the United States and Canada nearly forty-one millions of industrial policies against thirteen millions of annual premium policies (1917) — the amount insured thereby being respectively about $5,600,000,000 industrial insurance and $23,000,000,000 annual premium insurance (1917). About 91 per cent of the industrial business in America is in three companies — the Metropolitan Life of New York, the Prudential of Newark, N. J., and the John Hancock of Boston.

The following table shows the rapid growth of the business:

INDUSTRIAL INSURANCE IN THE UNITED STATES AND CANADA.

YEAR	Number of companies	Number of policies in force	Insurance in force
1880	3	228,357	$19,579,780
1890	9	3,875,102	427,882,964
1900	17	11,115,908	1,450,324,885
1910	22	23,044,162	3,179,489,541
1918	31	41,000,000	5,600,000,000

The following table shows how extensively the working classes take out this insurance, by a comparison of the population of five large cities, as estimated by the Census Bureau, with the number of industrial policies in force in three companies (other companies are doing business in most of these cities):

CITY	Estimated population, 1 July 1917	Number of industrial policies in three companies in force 31 Dec. 1917
Greater New York	5,737,492	3,995,708
Philadelphia	1,735,514	1,910,516
Saint Louis	768,630	866,875
Baltimore	594,637	681,430
Cincinnati	414,248	425,495

There are in the United States over 35,000 agents writing industrial insurance and the head office clerical force numbers several thousand. The industrial claim payments in 1918 were about $90,000,000.

Industrial insurance was introduced in Australia in 1884, but was not vigorously prosecuted until 1887. By the end of 1915 there were nine companies, with 623,790 policies in force, assuring £14,357,173. In New Zealand the government started the business of industrial insurance in 1875 but quickly discontinued it. In 1881 the government revived the work of the Industrial branch of its Insurance Department, but finally abandoned it in 1887. Among other British possessions there are a few small companies in South Africa and at least one office has been opened in India.

The business flourishes best in Anglo-Saxon countries. It has not attained large proportions anywhere else, except in Germany, where in 1914 there were 17 companies having nearly eight millions of policies in force for $375,000,000. The business is transacted on a limited scale in Austria-Hungary, Holland, Belgium, Denmark, Sweden, Norway, Finland, Switzerland and Brazil.

Policy Contracts.— We have said that the unit in industrial insurance is the five-cent premium or some similar unit; the amounts of insurance vary with the age of the insured and, during the infantile period, with the duration of the policy. The curve in the mortality table descends from birth to age 12 and then ascends and the companies for the same premium increase the amount of insurance each year after issuance of the policy, up to age 10. The amount of insurance thereafter does not decrease, for the policies are, like the annual premium policies, constructed with a level premium.

Policies are issued on various plans of insurance, efforts being constantly made to meet what appears to be the popular demand. For several years past a great majority in this country have been issued on the whole life plan with premiums ceasing at about age 70 or 75. The following table of the largest of the companies, which has in force nearly 42 per cent of the American business, shows the benefits payable on children for a five-cent premium under the company's principal infantile table:

INFANTILE WHOLE LIFE

Payment of premium ceases on first anniversary of date of issue after insured reaches age 74.

Amount payable provided death occur after policy has been in force for the following periods.

FOR A WEEKLY PREMIUM OF FIVE CENTS

Age next birthday	Under 6 Mos	6 Mos.	1 Yr.	2 Yrs.	3 Yrs.	4 Yrs.	5 Yrs.	6 Yrs.	7 Yrs.	8 Yrs.
2	25	25	34	40	48	58	70	110	150	214
3	25	34	40	48	58	70	110	150	208	
4	25	40	48	58	70	110	150	201		
5	25	48	58	70	110	150	194			
6	29	58	70	110	150	187				
7	35	70	110	150	180					
8	55	110	150	173						
9	75	150	167							

No policy issued under this plan at a higher premium than five cents.

It will be noticed that the amount payable increases materially after the policy has been in force for several years. The reason is that in the early years insurance is not needed in so large amounts and the unearned part of the premium charged is used to increase the amount of insurance in the later years. Technically in industrial insurance adult insurance begins at age 10 because the old actuarial tables were not carried below that age. Above 10, at each advancing age at entry, the amount of insurance for the same premium decreases, as can be seen in the next paragraph.

Notable increases in benefits have characterized the tables issued in recent years. In the largest American company there have been three substantial increases in the benefits under the whole life table, in 1907, 1909 and 1916 respectively. In 1906 the insurance for five cents for a person entering at age 10 was $120; now it is $162. For a person entering at age 20, the amount has increased from $87 to $113; at age 30, from $67 to $82; at age 40, from $50 to $58; at age 50, from $35 to $38. Moreover, the policies issued prior to 1907 did not contain the present provision for cessation of premium payments on the anniversary after age 74. For age two at entry, weekly premium five cents, the present benefit, after age 10 is reached, is $214; under the 1907 table the amount was $173; while in 1906 the amount was $120 after age 10, increasing by guaranteed additions to $138 at age 49, at which age the policy became an endowment. The amount in benefit below age 10 has in many instances been doubled. These increased benefits have been made possible by the improvement in general mortality, satisfactory earnings from investments and marked reductions in the expense rate.

Beside whole life, some of the companies issue other forms of policies, such as endowments maturing at age 80, and 20- and 25-year endowments. Twenty-payment life policies are little in demand. The largest of the companies issues in considerable numbers a novel and attractive contract known as the «Convertible» policy, which is a life policy with premium payments limited to a comparatively short period, after which the insured, if he desire to continue payment of premiums for additional short periods, may convert the policy into an endowment whose date of maturity is successively brought nearer and nearer as premium payments are continued. Twenty-five per cent of the Industrial business of the company mentioned is written on this convertible plan. Industrial insurance on the «group» plan has also been offered to the public, but the results have been negligible.

The provisions of the policies in industrial insurance do not differ in principle from the annual premium policies. They are usually incontestable after one or two years and free from restrictions as to residence and travel. Because of the small premium payable weekly and the rather superficial medical examination, full benefit is usually deferred six months or a year. In the principal American companies, only one-half is paid if death occur within six months, with full benefit thereafter. In Great Britain the first year benefits are rather less liberal than in America. The insurance under industrial policies is payable immediately upon receipt of proofs of death; and these proofs are prepared by the companies' agents without charge. The intention of the insurance being mainly to provide for expenses of sickness and

death, everything is done to facilitate the payment of the premiums to the company and of the claims to the insured. Collectors call weekly for the premiums; the companies have local offices convenient to the policyholders, for the payment of death claims and the service of policyholders generally.

Special Concessions.— Four weeks' grace are allowed in the payment of premiums, within which time claims are paid even if premiums have not been. In one of the largest companies, policies with premiums not more than twenty weeks in arrears are revived without regard to the health of the insured, and this practically has the effect of extending the grace period to twenty weeks. In the two other principal companies a similar concession is granted for thirteen weeks. Paid-up or extended insurance is granted upon lapse after three years, the provision usually being automatic — that is, no action being requred of the policyholder. Cash surrender values are usually granted after five or ten years. The weight of opinion is against early cash values, not only because they are small, but because they unduly tempt the policyholder in slightly straitened circumstances to give up his much-needed insurance. In cases of real need, however, the companies have adopted a liberal policy in the matter of cash values. Revivals are freely granted in cases of lapsed policies and where policies have been long lapsed, so that payment of arrears is difficult, the companies loan the amount of arrears on the security of the policies. Special allowances are made in cases of long strikes and lockouts, or of widespread suffering through calamities such as fire, flood or earthquake, death-claims usually being paid even if policies are lapsed.

Some of the companies grant full immediate benefit under adult policies in case of accidental death. The two largest of the American companies provide in their policies that in event of certain forms of total and permanent disability one-half of the insurance is immediately payable and a fully paid-up policy for the balance is issued at the same time.

Critics of the comparatively high cost of industrial insurance generally overlook the fact that much of this cost is incurred in the service that is rendered to the policyholder in sending an agent to his home weekly to collect the premiums. This fact is strikingly illustrated by a clause that has been incorporated in the policies of the largest American company for several years past and that has been made retroactive as to all of its existing policies, under which a premium allowance of 10 per cent is granted to any policyholder who has paid premiums continuously for at least one year direct to the home office or one of the district offices of the company. In this way the policyholder who is willing to forego the service of the agent is given the benefit of the saving of expense to the company.

Mutuality.— Prior to 1915, most industrial policies were issued as non-participating contracts. A change, however, came in 1915, one of the most notable years in the history of the business. On 6 January of that year the Metropolitan was converted from a stock to a purely mutual company and later in the year the Prudential of Newark also became in effect a mutual company, mutualization having been accomplished except for the non-assent of a very small minority of the stockholders. The mutualization of the Metropolitan was called by the Superintendent of Insurance in New York State in his annual report, «by far the most noteworthy event of the insurance year.» The mutuality of the Metropolitan, Prudential and John Hancock (long a mutual company) means that all but a comparatively small portion of the industrial policyholders in America now have — along with the annual premium policyholders — the right of control and the title to the profits of the business.

The fact that policies issued prior to 1915 were non-participating, however, had not deterred the directors of the larger companies from turning surplus earnings over to the policyholders. In 1897 the Metropolitan surprised the insurance world by voluntarily declaring dividends — or «bonuses,» as they were subsequently called, to distinguish them from dividends paid as a matter of contract — amounting to over half a million dollars to its industrial policyholders. These voluntary payments were continued each year, with important additions from time to time, finally reaching the sum of $6,000,000 yearly, and the company has the remarkable record of having paid or credited to industrial policyholders during the years 1897–1915, with no stipulation in the policies, expressed or implied, over forty-nine millions of dollars in its various forms of bonuses, while the additional cost of concessions in reserve liability exceeded four and one-half million dollars. The Prudential similarly paid or credited over twenty million dollars prior to mutualization. The mutualization of the companies, which extended participation to existing as well as new contracts, simply means that dividends to industrial policyholders, which in 1918 alone amounted in this country to over nineteen million dollars, have now become a matter of contract, rather than of purely voluntary action. Dividends and bonuses to industrial policyholders have taken the form principally of cash payments or credits on premiums, of additions to death claims or maturing endowments, and of relief to aged policyholders, either by maturing the policies as endowments or by waiving collection of premiums.

Mortality.— When the cost of industrial insurance is considered, the first thing to be noted is the increased mortality among the industrial classes. Let us compare the number per thousand dying at each of several specified ages according to (a) a United States Life Table compiled by Prof. James W. Glover from census returns for the eleven original registration states covering the deaths reported in the years 1909, 1910 and 1911; (b) the Medico-Actuarial Table, excluding the first four years of insurance, based on a portion of the experience of the principal American life insurance companies during the years 1885–1909 under annual premium policies, which table was used as a standard by the Joint Committee in charge of the recent Medico-Actuarial Mortality Investigation; and (c) death rates based on the experience of the Metropolitan Life Insurance Company during the seven years 1907–1913 on its standard industrial risks.

DEATHS PER 1,000

AGE NEXT BIRTHDAY	Glover's United States life table	Medico-actuarial table (ultimate)	Metropolitan industrial experience, 1907–1913
25	5.4	4.7	7.2
30	6.3	4.9	9.2
35	7.7	5.0	11.2
40	9.1	5.5	13.3
45	11.0	7.0	15.5
50	13.8	9.8	19.2
55	18.5	14.6	25.3
60	26.7	21.9	35.3
65	38.2	35.4	53.3

While the above tables are not in all respects strictly comparable, they afford a rough comparison of the mortality under industrial policies with that under annual premium policies and with the general population. A glance at these tables will show that the mortality under industrial policies at the above ages ranges from 150 to over 240 per cent of that under annual premium insurance. Industrial policies have shown a notable improvement in mortality in recent years — more so than annual premium policies — but it is likely that even at the present time, the mortality is at many ages more than double that for annual premium policies.

The comparison of industrial mortality with general mortality shows a less, but still large, percentage of difference. It is reasonable that it should be so, because, in the first place, industrial insurance in this country has not yet reached, in proportionate amounts, the agricultural and rural population, which is so large a percentage of the whole population. In the second place, the mortality of the working people in cities is large, because of the exposure, the mode of life, the hard toil and confinement, the carelessness of self which the observation of everybody must have noted among working men and women. To some extent there is also a selection against industrial companies, often unconscious, which is the correlative of the unconscious selection against whole life as compared with endowment policies in annual premium companies. A man vaguely conscious of low vitality will insure himself more readily than his opposite, just as one vaguely conscious of superior virility will prefer endowment to whole life insurance.

Insurance of Children.— The insurance of children has been the subject of much discussion in England and America and legislation against it has been proposed; but no law of prohibition has been passed in any State where the business has been well established. In England the law has remained for many years permitting the insurance of children within the limits previously adopted and maintained by the companies; and this after repeated Parliamentary investigations. In America, New York State in 1892 adopted as part of the insurance code a provision authorizing the insurance of minors according to the table of benefits in use by the companies. The New Jersey legislature also passed a permissive law in 1907. The Province of Ontario, Canada, adopted a similar table at about the same time as New York State and within the past few years the Provinces of Quebec, Saskatchewan and Alberta have taken like action. In upward of 20 States, as well as in the United States Congress, proposed legislation forbidding the insurance of children has been defeated — in many States repeatedly. In Massachusetts in 1895 the joint legislative committee took six weeks to investigate the subject, examining hundreds of witnesses, resulting in a vote of 143 to 29 against the prohibitive bill. Colorado is the only State which forbids the business and the law was passed there without a hearing of the company which had only recently begun business in the State — in other words, in anticipation of, not after experience of, evils. A bill introduced by the insurance department permitting child insurance is pending. So France, which is without experience of industrial insurance, and Belgium, where the experience has been very limited, have passed prohibitive acts, while in Australasia, where such insurance has been written for years, New Zealand has passed a law on the lines of the English permissive act. Under the law of New York State the maximum insurance permitted on a child under age two is $30; age three, $34; age four, $40; age five, $48; age six, $58; age seven, $140; age eight, $168; age nine, $200; age 10, $240. From the above and from the table of benefits previously printed, it will be apparent that at the earlier ages the insurance is simply burial insurance, while at the older ages it may amount to a very respectable sum. No case of child murder or abuse for insurance has ever been shown in the United States. In England the matter is thus summed up by Dr. Jones of the Royal Southern Hospital in Liverpool (where child insurance is most common and has been for many years) in a book 'On the Perils and Protection of Infant Life': «The incentive to child neglect and child murder is *not* the prospective receipt of insurance money.» In America, in 1905, the Armstrong Committee appointed by the Legislature of New York State, after the most searching investigation of life insurance ever conducted in this country, declared: «It may be added that the committee is also without facts which would warrant the prohibition of insurance of children. . . . In the absence of further evidence the committee believes that legislation would be unwise.» In fact, as time has gone on and industrial insurance has increased in magnitude and become better known, the realization seems to have come that criticism of child insurance has been founded on a very shadowy basis, for agitation against it, once so widespread, has in recent years practically ceased.

The companies usually limit the amount of child insurance to the amounts fixed by the New York statute, printed above; and the rule in case of over-insurance is either for all companies to cut down the payments proportionately or for the companies issuing the latest policies to return the premiums. No specialty of child insurance is made. Industrial insurance is, as we have said, family insurance. This is strikingly shown by comparing the percentage of population at various groups of ages, as shown by the last United States census, with

the percentage of premium-paying policies in force at the same ages in the largest industrial company:

AGES	Percentage of population census, 1910	Percentage of policies in force, 1910
1 to 4, inclusive	9.17	7.58
5 to 9, "	10.63	11.23
10 to 14, "	9.92	12.15
15 to 19, "	9.87	11.79
20 to 29, "	18.78	18.60
30 to 39, "	14.56	13.76
40 to 49, "	10.60	10.42
50 to 59, "	7.28	8.09

Expense.— Like everything else sold at retail, the cost of industrial insurance is high. Its cost, however, is scientifically adjusted. The loading on the net premium is necessarily much higher than that used in annual premium companies; and, as we have seen that the mortality is double at some ages, the cost of industrial insurance is necessarily great compared with annual premium insurance. The expense ratio is high because of the system of weekly collection of premiums, because of the large number of policies for small amounts which have to be recorded and cared for at the head office and the district offices and because of the heavy lapse rate during the early existence of the policies. As the premiums are payable weekly there are 52 opportunities each year for lapsing as against one to four in annual premium companies; and in the first year of insurance the lapse ratio is high. All of these early lapses are a pecuniary loss to the companies; and this partly accounts for the high expense ratio. Of the business lapsed within the first three years, more than one-third goes off within the first three months — much of it with only one or two weeks' premiums paid — and three-fourths during the first year of the life of the policy. The lapses in industrial insurance, while they cause a heavy loss to the companies, do not usually represent any serious loss to the insured. The premiums are weekly and the policies are carried on grace for four weeks after lapse, with a practical extension of the grace period to a term of from 13 to 20 weeks in the principal American companies, as previously described. Policies lapsing for non-payment of premiums can usually be revived upon evidence of insurability within one year, as a matter of policy contract, and after longer periods under the practice of the principal companies. Here there is no loss to the insured. In case the policyholder is unable to pay his arrears in cash, provision is generally made that they may be charged against the policy in the form of a lien. The largest company has recently offered special facilities for the revival of family groups on this plan. Here, again, the insured loses nothing. If the lapsed policy is not revived, but new insurance is taken, the amount of insurance at each advancing year of age is very little less than at the preceding age. If the policy is kept in force for three years, the insured is entitled to extended insurance or paid-up insurance for a reduced amount, the provisions varying in the different companies. After ten years, cash surrender values are available under policies now being issued — in one company, after five years.

It goes without saying that in all these cases lapses are no great source of loss to the insured. There can be no doubt that the lapses in industrial policies are very largely by those who subsequently take new insurance, suffering no loss at all in case of revival, and otherwise suffering only the small loss arising from partial benefits during the first year and the small decrease of benefits by reason of advanced age. The fact is there are many who insure and lapse and reinsure, according to their disposition of mind and their resources, with small loss to the holders but large loss to the company, which is put to the expense of commissions for placing the business and the large expense of caring for it. After three years the business is very persistent, comparing favorably with annual premium business. The average duration of the policies in force in the largest English company is nearly 14 years, and that of the policies of the largest American company (which has been in business for 25 years less than the English company) about nine and one-quarter years.

The proportion of lapsed policies has been very greatly decreased as the business has developed. This is forcibly shown by tabulations which were made by the largest company, whose business amounted to 42 per cent of the industrial insurance in this country, showing the lapse rate, during the first year, of industrial policies issued during various periods:

INDUSTRIAL LAPSE RATES

POLICIES ISSUED DURING	Per cent of issue lapsed during			
	First three months	First six months	First nine months	First twelve months
1896	38.17	52.71	58.58	61.87
1903	26.96	39.90	46.03	49.89
May, 1909	22.34	32.08	37.50	41.10
December, 1911	15.86	26.18	31.86	35.13
1916	10.79	18.90	23.19	26.04
1917	8.71	16.21	20.15	22.66

This company has for the last few years shown a remarkable record of the lapse of industrial policies compared with the lapse record of other large companies which do not do any industrial insurance business. In 1918 its percentage of terminations of industrial policies less revivals to the mean number of policies in force was 5.35. The corresponding percentage of the largest ordinary company which issues no industrial policies was 6.50. The industrial insurance company named showed 88½ per cent of the industrial insurance written in 1918 in force at the end of the year. Notwithstanding the weekly opportunity for lapse of industrial insurance, this was only six points less than the rate of persistence of policies in the ordinary department of the same company.

This decrease in lapses has been one of the contributing causes to a very remarkable reduction in the expense rate of industrial insurance, which has been effected through increasingly efficient management. In the largest of the companies the expense rate since 1895, exclusive of welfare expenditures, has been as follows:

1895	47.88 per cent of premium income
1900	43.84 " " " "
1905	42.80 " " " "
1910	36.07 " " " "
1915	33.40 " " " "
1918	33.22 " " " "

The increased economy of conducting the business has not been effected, however, at the expense of the agents; on the contrary, the average earnings of the agents in the company mentioned have more than doubled during the last 15 years, and the personnel of the agents has improved accordingly.

Intermediate Policies.— The expense of insurance to the industrial classes has been greatly reduced by the introduction of what are known as intermediate policies. These are policies which in 1896 the two largest industrial companies designed and issued for the working classes. They are policies for an even amount of $500 each, premiums payable yearly or in half or quarter years. The premiums are based on special tables of mortality compiled from the accumulated experience of risks of this class and the loading is less than that used by many companies for annual premium policies. The result is a moderate priced ordinary policy contract issued on all the usual forms — whole life, limited payment and endowment — with participation in surplus earnings. A working-man who has got beyond the necessity of making small weekly payments and can afford to pay dollars annually where he has been paying cents weekly, finds in these policies insurance whose cost does not differ greatly from that his rich neighbor buys. In fact, in many instances, particularly under endowment policies, which constitute most of this business, intermediate insurance has actually proven cheaper than other ordinary insurance. There were at the end of 1917 about 1,250,000 intermediate policies in force in the United States and Canada, insuring over $600,000,000. The English Prudential had at the same date 929,618 ordinary policies in force, of which a very large proportion is endowment, averaging about £112 per policy, the premium averaging a little under £6. The English Prudential policies are also as a rule participating. The industrial companies on both sides of the water claim that by the issue of this class of policies they have perfected the system of industrial insurance and have performed their full duty to the wage-earners by furnishing insurance adapted to the condition, means, habits of life, and requirements of all; weekly premiums for those who can afford no better, and for those of an age unsuitable for large insurances; annual premiums for small policies with dividends as earned, bringing the cost down as nearly as possible to the cost of ordinary insurance as purchased by the well-to-do.

Moreover, industrial or intermediate insurance is often merely a stepping-stone toward ordinary insurance for larger amounts. Great numbers of persons insured under industrial policies, adult as well as infantile, later on become financially able to carry the usual forms of ordinary insurance, and their industrial policies have educated them to the value of insurance, which they might not otherwise have realized. It was almost inevitable that the industrial companies should develop an extensive ordinary business. As a matter of fact, the growth of ordinary insurance in the industrial companies has been one of the notable features of recent years, the amount of ordinary insurance in force at the end of 1918 (including intermediate) in the three principal industrial companies in America having reached the remarkable total of $4,237,809,392.

Welfare Work.— Few organizations have the opportunity of reaching and influencing so many people as the industrial insurance companies. The great force of agents going weekly into millions of homes affords a direct means of communication from the company to the policyholder, and the frequency of the agent's visits tends to make him the friend and counselor of the families from whom he collects.

The exceptional opportunity for social service thus afforded has not been overlooked by the companies. They have been active, particularly in recent years, in many branches of welfare work. The principal media of communication between the companies and their policyholders, aside from the agents themselves, are the magazines which are issued by most of the companies several times a year for distribution among policyholders. It has been the object of the companies through these magazines to stimulate better physical, mental and moral development. Special attention is given to the dissemination of information and advice in matters pertaining to health and general welfare. In addition to the magazines, some of the companies issue health literature in the form of leaflets or pamphlets for distribution among not only policyholders but the general public.

The industrial companies have unusual facilities not only for distributing information but for obtaining it. The great number of policyholders under observation, along with the close relations between the agents and the policyholders, give the companies the opportunity to collect information of great social value relative to such matters as mortality, morbidity, unemployment, etc., and some of the larger companies have experts who devote their energies to the study of these subjects.

The Metropolitan Life Insurance Company of New York, which in recent years has specialized to an unusual degree in welfare work, has distributed over 187,000,000 copies of pamphlets and leaflets, has maintained a free nursing service for the benefit of its industrial policyholders, under which more than 1,400,000 visits were made in 1918, has conducted extensive sickness and unemployment surveys — the latter in co-operation with the United States government,— has given numerous welfare exhibits at fairs, expositions, etc., and has rendered invaluable assistance to State, county and municipal health bodies, through the co-operation of its agency force and otherwise, in their efforts to improve the public health, such as «clean-up» and «baby-week» campaigns, education relative to tuberculosis, Spanish influenza and to health laws, and the distribution of circulars in support of proposed health legislation.

Relation of Industrial Insurance to the War.— Two facts stand out prominently in connection with the Great War. One is the inherent soundness of the industrial companies, even under the most trying conditions, and the other is their opportunity for usefulness. The

severest test has been, of course, of the European companies, which have had to contend with war conditions since 1914. The British companies almost without exception waived all war restrictions on policies issued prior to the beginning of hostilities. Up to the end of 1917 the Prudential of London had paid over 160,000 war claims, exceeding £3,400,000, by far the larger portion of which was on industrial policies. In spite of the excessive death losses and of the depreciation in securities and heavy war taxes, the company remains in sound financial condition. There has naturally been a reduction in the dividends to policy-holders and stockholders. The British companies have rendered noteworthy service in ambulance and other Red Cross work, and in many other war activities.

In the United States, war restrictions in industrial policies were likewise waived on policies issued prior to entrance into the war. Even the policies subsequently issued are free from war conditions up to a certain amount of insurance. In one company the amount is $300. Following the armistice, the $300 limit was removed. Valuable service has been rendered to the United States Government by the agency and home office forces in such essentials as food conservation, recruiting, classification of military census forms, Red Cross and other war relief work, distribution of a wide variety of literature, and the selling of government securities issued to carry on the war. The United States Treasury Department appointed Mr. James E. Kavanagh, fourth vice-president of the Metropolitan Life, as assistant to the chairman of the National War Savings Commission, and Mr. Kavanagh was made the organizing head of the government's campaign to organize War Savings Societies and sell $2,000,000,000 of War Savings Stamps. The larger industrial companies, through their agents and home office staffs, inaugurated an active campaign for the sale of the stamps, and the Metropolitan fixed its goal for the year 1918 at $65,000,000. This was passed at the end of August, and the total sales at the end of the year were over $112,000,000, besides over $21,000,000 in the Fourth Liberty bonds, the campaign for which was interjected into the War Savings Stamp campaign.

Both in Great Britain and the United States the industrial companies have subscribed very largely to the various war loans issued by the government. It has been stated that at the end of 1917 the London Prudential held over £25,000,000 of the British 5 per cent war loan. In this country the Metropolitan has taken about $100,000,000 of United States Liberty Loans and Canadian War Loans; the Prudential of Newark nearly $90,000,000, and the John Hancock over $13,000,000.

HALEY FISKE,
President of The Metropolitan Life Insurance Company.

INSURANCE, International.—At the beginning of the European War in 1914 a plan was proposed for extending the application of insurance to international affairs by means of a fund realized from the contributions of a community of nations joining to provide indemnity against certain common general hazards, such as earthquakes, volcanic eruptions, migratory pestilences, tropical diseases, destructive storms, famine, crop failure, marine disaster, and, above all, the hazard of war and losses falling in war time on private property belonging to citizens of neutral states. The absorption of public attention by the war prevented a wide discussion of the proposal, but a new and surprising development of the insurance idea may easily result from the conference for a world peace that alone can settle the World War. Consult 'War and Insurance' by Josiah Royce.

INSURANCE, Life. Life insurance is the application of insurance to loss or injury caused by death. It may be defined as a contract under which one party called the insurer, in consideration of certain stipulated payments, termed premiums, agrees to pay to another a moneyed benefit upon the happening of a contingency dependent on the duration of a human life. The person whose life is the subject of the contingency is termed the insured, and the party receiving the benefit the beneficiary, while the benefit itself is called the insurance money. The contract when in writing is known as a policy. In practice the contingency involved is either the death or the continued survival of the insured. If the benefit is to be paid upon the death of the insured, it is known as a strictly life insurance contract, if upon his survival to a given age, it is called an endowment. The issue of such contracts is confined to companies incorporated for the purpose and to benevolent and fraternal associations. The fundamental object of life insurance is the protection of families and dependents, or of business interests from the pecuniary loss which is liable to result from the death of the party insured. It furnishes a method of at once providing a fund which shall be available in case of such misfortune, by means of a series of limited payments made during the continued life of the insured. The latter is able for a small consideration to secure the benefit of an immediate investment payable upon the expiration of the contract, instead of awaiting the slow and uncertain process of accumulating a capital which may be defeated by his untimely decease. The business man is thus enabled also to protect his creditors or his business as well as those dependent on him. In case of the endowment the policyholder is able to unite such protection with a fund available for his own use should he survive during a stipulated period. In short, life insurance may be regarded as a method of purchasing immunity against moneyed misfortunes liable to result from death, and appeals with special force to those whose chief dependence is on their daily or yearly earnings. It offers peculiar advantages, too, because it can be placed beyond the reach of creditors and need not be involved in business misfortunes, while the policies themselves can be hypothecated or sold like ordinary commercial securities.

The policies are issued by the companies upon written applications from the purchasers, in which detailed statements are required regarding the health, habits and family history of the applicant, accompanied by the certificate of a physician based on a careful examination. The policy stipulates as to the amount and character of the benefit to be paid, the party to whom it is payable and the premium payments to be received, together with such other provisions as may be needed to express the complete

contract with the applicant. The premiums are usually payable annually or at shorter intervals in advance. The business is done almost entirely through agents who solicit the applications, collect the premiums and otherwise act as intermediaries.

History.— Life insurance in its more modern form was practically unknown until it was introduced into England by the establishment of the Amicable Society in 1696. Other companies were gradually started there. But for many years afterward it was prohibited on the continent of Europe as immoral. Modifications of the system, however, known as annuities and tontines had long been familiar, and the former had been employed as a basis for national loans. It was not until the 17th century that sufficiently reliable observations on human life were compiled to furnish a satisfactory foundation for the business, and that the commercial elements of society attained an importance sufficient to give it the needed support. Companies thereafter multiplied in Great Britain and the business gradually extended to the continent of Europe.

Life insurance was introduced from Great Britain to America, and the first society was organized in Philadelphia in 1759 for the relief of Presbyterian ministers and their widows and children, followed 10 years later by a similar corporation for the benefit of Episcopal clergymen and their widows. Their operations, however, were confined to the classes named. The first company to attempt a general business was the Insurance Company of North America, organized in the same city in 1796. A number of other companies gradually followed in that and other important cities during the earlier part of the 19th century. All these earlier offices, however, combined fire or marine insurance, or banking and trust business, as well as annuities with life insurance, and gradually abandoned the latter. Popular prejudice proved to be too strong, and the economic condition of the country to be too little developed to make its prosecution successful. The real beginning of modern life insurance in the United States dates from the organization of the Mutual Life Insurance Company in New York in 1843, which was quickly followed by that of others, both there and elsewhere, some of which had already secured charters for the purpose. The business of these new companies was confined to life insurance, and their success led to the gradual multiplication of such companies until within 20 years it had attained proportions which made these corporations among the most important financial institutions of the land. The business has since continued to expand until the enormous sums now invested in life insurance in America far exceed those in any other country. Its leading institutions are unrivaled in their size elsewhere, and several are transacting business in every quarter of the globe.

Insurable Interest.— Every form of insurance presupposes some pecuniary interest in the subject insured, without which it would be a mere speculation or gamble and a temptation to crime which public policy does not permit. Where the insurance is on property, such interest on the part of the insured must usually be commensurate with the amount of the insurance. The insured is restricted in his recovery on the policy to a sum which will indemnify him for his loss. This doctrine, however, is relaxed in case of life insurance, since no strictly moneyed value can well be placed on a human life. The principle of indemnity goes no farther here than a requirement that the party procuring the insurance shall have such an interest in the life insured as shall prevent the contract from being a mere gamble on its survival. Any reasonable expectation of pecuniary advantage from the continuance of the life is deemed sufficient, such as dependence or the payment of a debt. Every person, too, is assumed to have an interest in his own life, which he may insure to any amount, and may make the policy payable to any beneficiary whom he may elect so long as the scheme is not a mere cover for gambling.

Classes of Companies.— Life insurance is carried on by two distinct classes of institutions. One consists of those which treat it as an ordinary commercial or financial business, the other, of those which deal with it as a form of benevolence or fraternal aid. The former may be again divided into those in which the premiums are definite in their amount and time of payment, and those which depend on assessments from their policyholders to pay claims as they become due. Life insurance as a business, however, is chiefly carried on by the first mentioned, which are known as old line or legal reserve companies. It has been found the only business method which has successfully stood the test of experience. Two systems have been adopted in this class of companies. One is the mutual, in which the policyholders are regarded as the owners of the corporation, and all profits or surplus arising from the business are distributed among them. Such surplus performs the functions of an ordinary capital. The choice of directors or trustees and consequent management of the company is usually placed in the hands of the members. The majority of companies in the United States are conducted on this system. The other is the stock plan, in which the company is owned and controlled by stockholders, who deal with the policyholders simply as customers and divide the profits of the business among themselves. Higher premiums are charged for mutual policies for the purpose of creating a surplus, which may be eventually returned in dividends to the policyholders. In the stock policy, on the contrary, the holder sacrifices the right to dividends in exchange for a lower premium rate. Some of the companies combine both features, mutual offices issuing also stock policies, known as non-participating, at lower rates of premium. Often, too, a stock capital is added to a mutual company which is restricted by the charter to the amount of dividends which it can receive. When the stock is allowed to share in the profits in excess of its legitimate earnings as an investment, the system is known as the mixed plan. Sometimes, too, the election of directors is apportioned between the stock and policyholders, or, in a company otherwise mutual, may be restricted to the former. In many of the States a capital stock is required by law in the organization of a mutual company until it can be replaced by surplus belonging to the policyholders. The distinctive feature of the legal reserve company, apart from its fixed premiums, is that it must at all times maintain a reserve fund adequate to the payment of its

future obligations, less the future premiums which it will receive; in other words, it must in a commercial sense be financially solvent. It is also known as an old line company because conducted on the principles which have always characterized life insurance as a business until the introduction of the assessment plan.

Assessment companies were started in the United States over 50 years ago for the purpose of furnishing life insurance at lower rates than those charged by the regular old line companies. Instead of a fixed premium, assessments were levied on the policyholders to pay the losses as they occurred. Various methods were adopted for levying such assessments, and, as the policyholders were in theory liable for whatever assessments were needed, they only became insolvent when unable to meet their claims. The plan was an adaptation of methods employed by fraternal orders, and for a while was exceedingly popular among those seeking a cheap form of insurance, since the actual cost of insurance being low in the early years, the assessments were correspondingly light. But the increased cost as time went on ultimately so increased the assessments that it was found impossible to enforce them, and most of the companies were compelled to retire or change their methods. Comparatively few now remain, and the system itself has been condemned by many of the State authorities. Many of the companies were accustomed to assume the character of benevolent organizations in their operations.

Stipulated premium insurance is a combination of the assessment and legal reserve systems with a view to correct the defects of the former. The premiums, as in the old line company, are definite payments, supplemented, if needed, by assessments, and a moderate reserve is carried to reduce or render such assessments unnecessary. It has been employed by some of the assessment companies as a method of establishing their business on a firmer foundation. But life insurance as a business in the United States, as well as in other countries, is chiefly done by old line legal reserve companies, whose definite contracts, financial strength and scientific business methods give to such contracts a commercial standing unattained under any other system.

Industrial insurance is a branch of the legal reserve designed to furnish burial funds for the poorer classes, and especially children. Its principles do not differ from those of ordinary insurance, but its methods are essentially different in many respects owing to the small size of the policies and the character of the applicants. The premiums are payable weekly or at short intervals, and are collected by agents through house-to-house visitations. It was introduced into the United States from Great Britain about 50 years ago, having been an outgrowth of the burial clubs and friendly society system of that country, and has attained enormous proportions in America, as well as Great Britain. See INSURANCE, INDUSTRIAL.

Fraternal and benevolent societies have been popularly associated with assessment companies owing to the similarity of their methods. But they are a distinct class, having the character of social clubs solely for fraternal or benevolent purposes, with a form of insurance as merely one, though it may be their most important, feature. They are strictly mutual in their character. Their general type of organization is that of the ordinary society or club known as a lodge, whose members meet for social or fraternal purposes. The society is formed of a combination of such lodges, through chosen representatives, into a single grand lodge, by which the insurance is carried on, the subordinate lodges acting the part of agents in securing members and collecting the payments. The insurance itself is simply a death benefit allowed to the members under provisions in the constitution, and not a business contract secured by the purchase of a policy. The premiums are paid in the form of dues and assessments, much after the manner of assessment companies, the dues being used for expenses and other incidental features. Efforts are being made to scientifically adjust the payments and benefits of these societies according to the cost of insuring the various members, as is done in the legal reserve companies. The insurance which they furnish is regarded as a species of fraternal aid to the members and their dependents, and their operations are not subject to the same legal constraints as those of business corporations. See INSURANCE, FRATERNAL.

Mortality Tables.— The life or mortality table, from which the premiums must be determined, is at the foundation of the business. The tables mostly employed are constructed from the experience of the companies themselves with insured lives which have been found to have a mortality distinct from that of the population at large. Such a table in its simplest form consists of a statement of the number surviving at the beginning of each succeeding year out of a given number living at any age, from which the number of deaths and percentage of mortality at each age are readily determined. The latter is the important function employed in life insurance. In America the two tables which are chiefly used, and which have been recognized by the various States as standards for determining the liabilities of the companies, are the Actuaries or Combined Experience and the American Table. The former was constructed from the experience of 17 prominent English offices, and was published in 1843. Its general accuracy has since been confirmed by later observations. The American Table was constructed from the experience of the Mutual Life Insurance Company of New York, and came prominently into use about 1868. It was found to represent the actual experience of American companies better than foreign tables which had been employed. Many other mortality tables have been constructed which have obtained a recognized standing. Prominent among them were the Northampton and later the Carlisle Table, both of which were framed from mortality returns of English towns, and were successively used both in England and America, until replaced by the Actuaries' Table. Farr's Tables, constructed from the census returns in Great Britain and published in 1864, have been much used for certain purposes. Various tables, too, have been constructed from observations in other European countries and employed there as standards. The three requisites of such tables for insurance purposes are that they should be safe, should be properly graduated, and should fairly represent the mortality to be expected.

Premiums.— The premiums, which must equal the cost of insurance, are computed from the risk of death, as shown by the mortality table; and since the former are usually fixed sums, while the risk increases with age, it is necessary to charge more than the actual cost in the early years in order to offset the deficiency later on. This excess above the cost is accumulated at compound interest by the company, and constitutes its reserve fund. The rate of interest assumed in the calculation is such as the company is justified in expecting will prevail during the continuance of the contracts. In the United States 4 per cent was formerly considered a safe rate, but the continued fall in interest has led to a general substitution of 3 or 3½ per cent for newer contracts. The payments, which, when thus accumulated will be sufficient on the average to meet the claims on the policies as they fall due, are known as the net premiums, to which additional sums are added for expenses and other contingencies. When thus loaded they are known as gross or office premiums, and are the real amounts charged by the company. These loadings may vary from a trivial addition to 40 per cent or more of the net premium, according to the character of the contract. Premiums in ordinary insurance are usually payable annually in advance, and are then known as annual premiums. Frequently the payments are restricted to a certain number or term of years. These are known as limited payments. Sometimes the entire payment is made at the start. This is known as a single premium payment. The annual premiums, too, are sometimes payable in instalments at shorter intervals to suit the convenience of the policyholder.

Expenses.— The expenses of a life company are chiefly made up of two classes, the cost of securing the business and the office expenses incident to its care. The principal element in the former is the commission or other compensation paid to the agents, which also varies with the character of the contract. It is usually a large percentage of the first premium paid, and a more moderate percentage, in the nature of a collection fee, for those succeeding. The office expenses aside from the salaries of the officers and employees include taxes, fees, rents and those numerous items involved in the care and investment of funds and the conduct of the business.

Legal Reserve.— The legal reserve is the measure of an ordinary life company's liablity on account of its insurance contracts to which, in addition to any other liabilities, its funds must be equal in order that it may be legally solvent. The process of estimating this reserve is known as valuing the policies. Two methods of valuation are used, known as net and gross, dealing respectively with the net and gross premiums charged. The former is generally employed in the United States, and is the one usually adopted by the State authorities. It consists in determining what fund the company must have in its possession in addition to the future net premiums which it expects to receive in order to meet future claims on its policies. This fund is the net or legal reserve. It assumes that all other expenditures are cared for by the premium loadings. The gross valuation, on the contrary, deals with the gross or office premiums, and a certain deduction is made from the resulting fund for assumed future expenses. The latter method is regarded as furnishing the surest test of a company's actual condition, and is sometimes employed when the question of legal solvency is in doubt. The former has the advantage of compelling the use of the premiums for the purposes assumed by the company in their computation.

As in the case of the premiums, the computation of this reserve depends on the future rate of interest which is assumed. In most of the States 4 per cent, as in the case of premiums, was formerly regarded as a safe rate, and even 4½ per cent was at one time allowed, but during recent years 3 or 3½ per cent have been insisted on in the case of new contracts by many of the States.

The mortality on which the sufficiency of the premium depends is lighter in the case of insured lives, owing to their careful selection, than among the general population or that called for by the mortality table for a number of years after the policy has been issued. The cost of insurance in mutual companies is reduced to the policyholders by this lighter mortality. In American companies the mortality among lives that have not been newly selected remains nearly stationary after age 20, or increases but slightly until age 40 is reached, when it is not far from 1 in 100, increasing more rapidly with each age thereafter until it is about 2 per cent at age 50 years and 4 per cent 10 years later.

Form of Contract.—As before remarked, policies may be either participating or non-participating, the chief difference being that smaller premiums are charged in the last and no provisions are included for sharing the profits. Policies for short terms are more frequently made non-participating. The classes of policies most in use are three in number, whole life, term and endowment. In the first the insurance is simply against death and covers the whole term of life, while in the second it runs only for a certain term of years. The pure endowment is an insurance payable at the end of a certain term of years only in case the insured is alive, and is the reverse of a term policy. The ordinary endowment which is almost exclusively used, however, and which has of recent years largely supplanted the whole life policy, is a combination of the pure endowment and the term policy. The insurance money is payable to the insured if alive at the end of the endowment period, or to some beneficiary in case of his previous death. Such endowments are usually issued for periods of from 10 to 30 years.

The annuity is a contract frequently combined with life insurance in which the life insurance principle is reversed. The purchaser buys outright a contract under which he is to receive an annual payment during life. Annuities have been familiar since an early period, and before life insurance became understood was the principal form of contracts dealt in by this class of companies. It secures a fixed income during life to those who may wish to surrender their capital for that purpose.

Still another form of contract is the tontine, in which the funds of a body of subscribers are pooled and the accumulations are divided among the survivors after a certain time. Societies of this kind were formerly common in Europe

and were occasionally found in the United States, though few, if any, remain.

All these different contract forms are now frequently combined in various ways in the ordinary life policy, in order to increase its attractiveness or to better meet the requirements of policyholders. Various methods of premium payments and of paying dividends are also combined for the same purpose. Great ingenuity has been displayed by the companies in making these combinations, and an almost innumerable variety of contracts have resulted. Among those more familiar in the United States are the tontine or deferred dividend policies, in which dividends are accumulated and divided among the surviving policyholders after a certain period; limited payment policies, in which the premiums are limited in number; and instalment policies, in which the insurance money, instead of being payable in a single sum, is converted into a series of annual payments as an annuity. Besides, there are policies insuring the life of more than one party. When they are payable upon death of either of the parties insured, they are known as joint life insurances; when payable only on the death of all they are survivorship insurances. The greater part of the business in the United States is written either in the form of continued payment life, 20-payment life, or 20-year endowment insurance. Renewable term insurance is another plan for reducing the cost of insurance during the early years and avoiding the accumulation of a reserve. The premium is only sufficient to pay for the temporary cost of insuring and increases with age. The policies are written for a single year or term of years, with the right to renewal at the increased premium. The subsequent increase of cost, however, has been found a serious obstacle to the plan. Preliminary term insurance is also insurance for a single year, but with a right of renewal for the entire period at the same rate of premium. The object of such policies is to enable the company to use the fund which, under the law, must otherwise be added to the reserve during the first year of insurance to meet the cost of securing the business, and has been a favorite method with young companies having a limited surplus.

Dividends.— Dividends are apportioned from the accumulated surplus according to the equitable share of each policy. Many different methods of determining this share have been devised. That chiefly employed in the United States is what is known as the Contribution Plan. The surplus is treated as made up of gains from a lower mortality and expense and a larger interest earning than those assumed in computing the premiums, and the contribution of each policy to the fund is estimated. Dividends are applied according to the provisions in the policy in various ways. They may be used as single premiums to increase the amount of insurance, which is called a bonus addition, or to shorten the term of the insurance, or to the payment of the premium, or may be received in cash. When, as in tontine dividends, they are to be apportioned among a special class, the share of surplus belonging to that class is separately dealt with. Sometimes a minimum future surplus earning, which can be relied on, is made the basis for guaranteeing the payment of a certain dividend in the policy. But as such earnings are uncertain, the usual estimates of these amounts, as given by the companies, are simply expectations and not obligatory as promises. The fall of interest rates has tended to reduce dividends during recent years. At an earlier stage of life insurance, dividends were payable at intervals of five years or more. Afterward, as the business became better understood, the practice of declaring annual dividends in the United States became universal. The subsequent introduction of deferred or tontine dividend policies lengthened the distribution period of the classes to which they were applicable and for a while such policies became exceedingly popular, but the resulting abuses led to their prohibition and a compulsory return to annual dividends. Notes were at one time received by many of the companies in part payment of premiums, but the practice has been for the most part abandoned.

Policy Loans.— Practically all forms of life insurance in which a level premium is paid involve an investment or savings bank element, which is represented by the reserve and is now treated by the law and the contract as belonging, in a sense, to the policyholders. This is the basis of the policy loans which are so generally granted. The portion of the reserve fund belonging to the individual policy, or a portion of it, may be borrowed by the policyholder as a loan bearing interest, on his own note with the policy as a collateral, and is deducted from the insurance money when the policy becomes payable.

Termination of the Contract.— The life insurance contract is terminated either by becoming a claim, which is usually payable at once after satisfactory proofs have been furnished, or by previous lapse or forfeiture through a violation of its conditions, especially non-payment of the premium, or through a voluntary surrender. Policies usually provide for their surrender and allow the insured to receive back a large part of the reserve held against them, called the surrender value, either in the form of paid-up insurance for such an amount as this value will purchase, or insurance of the original amount for such a term as it would pay for, called extended insurance, or else in the form of cash. Statutes in many of the States require similar returns in case of lapse for non-payment of premium, and such provisions are also usually incorporated in the policies. Non-forfeiture laws, as these statutes are called, are designed to prevent the assumed hardship or injustice entailed on the insured through the forfeiture of the money standing to his credit in the reserve fund. This money is regarded as a saving bank accumulation for his future benefit, which is in a sense his property and which should be restored after reserving a surrender charge to compensate the company for his loss. Since healthy lives are most likely to lapse and the cost of insurance to be made greater for those who remain, the selection against the company, as it is termed, is an important element in determining the surrender charge.

Insurance for the Benefit of Wife and Children.— The fundamental object of life insurance as a family protection is liable to be defeated if the policies can be attached for debt. Therefore, statutes have been enacted in many of the States exempting from the claims of creditors policies up to a certain amount

made payable to wives and children. The interests of such parties, too, have been held unassignable, at least without their consent. The life insurance contract, except in the case of benevolent societies, is held to be the property of the party who is the beneficiary. when not otherwise stipulated, and not of the party who may pay the premiums, and can usually be assigned as collateral or sold outright by the owner. Policies not protected by statutes, as above, may, like other personal property, be attached for debt to the extent of their surrender value; and where, as in endowments, two interests are sometimes involved, the interests may be severed.

Medical Examinations.— Medical examinations of applicants for insurance are essential to prevent an inroad of unsound lives that would wreck the company, whose mortality rates are based on the acceptance only of healthy lives. For this purpose medical examiners are employed, who report the health, physical condition and habits of the applicant and the life history of his near relatives. These reports are passed upon by the medical directors of the companies to determine whether the life is up to the normal standard fixed by the company, otherwise the application is rejected.

Sub-Standard Insurance.— Parties who may not be seriously diseased and yet who are not insurable as healthy lives, on account of constitutional weakness or predisposition, are known as sub-standard or under average lives and are insured by some companies as a separate class under special rates of premium, or under special policy conditions, according to the defects of each applicant.

Limitation of the Risk.— Formerly many restrictions were imposed in the policy as to the residence, travel and personal habits of the insured, and military employment and suicide were debarred. These have been gradually modified or removed, until it has become customary with some companies to issue so-called indisputable policies, which in the absence of fraud, can only be forfeited by failure to pay the premiums.

Moral Hazard.— The moral hazard in the business arises from deceptive representations as to health, the temptation to insure as a mere speculation lives in which no insurable interest exists, in the expectation of an early death and the temptation to destroy life through suicide or murder in order to secure the insurance money. The ability of an average applicant to judge of his future health is shown in the higher death rates among those classes of policies where an early death would profit the applicant and is an element of the moral hazard.

Legislation and Supervision.— Until about 1860 little or no supervision was attempted over life insurance by the various States. Legislation concerning it was chiefly confined to taxation of the companies or restrictions on their operations. The multiplication of irresponsible corporations, the growing magnitude of the business and the recognition of the dangers involved in its mismanagement, led to the creation of special departments for its supervision, and the enactment of laws for its conduct by the States of Massachusetts and New York. Their example has been followed by most of the other States. The fundamental aim of these laws is to compel the companies so to utilize and apply the moneys which they receive as properly to carry out the contracts with their policyholders. This is accomplished by requiring the funds in the company's hands to be at all times sufficient, together with its future accumulations and the future premiums and their accumulations receivable from its policyholders, to meet its future claims as they arise. Since the proper investment of these funds is also essential, this becomes an important part of the investigation, as well as the general manner in which the business has been conducted. Annual statements are required from the companies, embodying the facts essential to such an inquiry, and may be supplemented, if necessary, by a personal examination of the company on the part of the State official. Failure to meet the required test may be followed by a prohibition against additional business until the defect is remedied, or, if actual future insolvency is threatened, by proceedings to close the company. Within the last few years these legal restraints have been greatly increased in many of the States and the companies have been closely restricted as to their forms of contract, expenditures and business systems.

Theory of Life Insurance.— The fundamental problem in life insurance is to find the average premium at each age, which, with its accumulations, will be just sufficient to meet the promised future payment. This is done by first finding the present value of that future payment, or the sum which, invested immediately at compound interest, will, on the average, with its accumulations, meet this payment when due. The probability of death occurring, and consequently the payment becoming due, during any subsequent year is determined from the mortality table. This probability, multiplied by the sum which accumulated to the end of that year would equal the required payment, is the present value of the payment if made that year. The aggregate of such values computed for each successive year of life, is the entire present value of the future payment to which the present value of the premiums to be charged must be equal. These premiums are in effect so many annuities receivable by the company, and their present value is the amount which, at once invested at compound interest, would reproduce them. The problem, therefore, now becomes the determination of the present value of an annuity at any given age. The process is analogous to that already described. The value sought is the aggregate of the amounts which, at compound interest, would provide the annuity at the beginning of each year, multiplied by the probability of the insured being then alive to pay it. Having determined the present value of any given annuity it is easy to find the annuity which has the value required. This annuity is the net premium.

Life Insurance a Science.— This brief explanation will serve to illustrate the general character of the problems involved in the theory of life insurance, many of which are exceedingly complicated and require a knowledge of the theory of compound interest and of the calculus of probabilities, which, when combined, form the mathematical basis of life insurance. The calculus of finite differences has also an important place, and even the infinitesimal calculus has been utilized to advantage,

especially in preparing mortality tables. This whole subject has been developed into a special branch of mathematics termed actuarial science, which has become a recognized profession, whose members, known as actuaries, direct the mathematical computations required for the business. A special class of symbols has been devised in connection with this science, by which the processes involved in its various calculations are readily expressed in the shape of ordinary algebraic formulas. Life insurance computations have been greatly facilitated by an ingenious device known as commutation columns, through the use of which the calculations are much simplified. Published tables of premium and annuity rates and policy values, in connection with the more important benefits, too, relieve much of the office work.

WALTER S. NICHOLS, A.M.,
Former Lecturer on Insurance at Yale University, and Editor of the 'Insurance Law Journal' and 'Insurance Monitor.'

INSURANCE, LIFE, Statistics. The growth of life insurance and its large place in modern affairs can best be appreciated from a tabulation of the aggregate results since its beginnings in America three-quarters of a century ago. Starting in Great Britain near the opening of the 18th century, the idea took a small hold in the American colonies shortly after the middle of the same century but came to real utility 100 years later, since which time the American business companies and fraternal insurance orders have far outstripped the Old World in their extension of life protection.

The first corporation to attempt life insurance in America, the Presbyterian Ministers' Fund, was chartered in 1759 and is still in flourishing existence. It began on the assessment plan, but changed some years ago to the legal reserve plan. This is not, however, a general business company. Several annuity companies started later, but business insurance took its first earnest start with the Mutual Life Insurance Company of New York, which began operations in 1843. The New England Mutual followed a year later, the Mutual Benefit two years later and the New York Life, also mutual, a few weeks after the last named.

Thereafter the number of companies increased steadily but slowly until the close of the Civil War, when life insurance organization was seized with a speculative craze and companies multiplied rapidly; but the panic of 1872 exposed the weakness of scores that were insecurely founded or poorly managed. The number of companies doing business in New York State rose from 14 in 1859 to 71 in 1870, and fell back to 29 by 1881. The amount of business outstanding decreased about 30 per cent between 1870 and 1881.

The next period of expansion set in with the legislative investigations of 1905. Most of the larger companies have been or have recently become mutual. Many of the newer companies in the southern, central western and far western sections of the United States are capitalized and the total of capital employed rose from $22,724,130 in 1906 in 138 companies to $54,764,732 in 241 companies in 1916; the dividends to stockholders increased from $956,520 to $5,149,076 as between the two dates.

Table I shows that a large proportion of companies existing in 1917 were still young as compared with those that survived the stress of the 70's. A list of 309 American companies that have failed, reinsured or retired is given in the 1917 'Spectator Year Book,' from which the following data are gathered.

TABLE I.—AGE OF EXISTING AMERICAN LIFE INSURANCE COMPANIES TO 1917

DATE OF ORGANIZATION	Number of companies	Years in business
1847 or before	8	70 or over
1857 "	17	60 "
1867 "	29	50 "
1877 "	36	40 "
1887 "	37	30 "
1897 "	41	20 "
1902 "	60	15 "
1905 "	87	12 "
1907 "	114	10 "
1917 "	248	1 "

Table II exhibits the aggregate of results since organization of 194 of the existing life companies and gives the principal items, not including assessment societies or fraternal orders. The showing is impressive from a financial as well as an economic point of view In recent years business assessment societies have greatly declined, while fraternal orders have advanced. Adding the nearly two and a half billion benefits paid out by these societies and orders to the death claims shown in the table, it appears that altogether over six and one-half billion dollars have been paid out to this account during the past 75 years by American corporations. Imagination can hardly exaggerate the economic blessing of this provision to hundreds of thousands of families which would have been left embarrassed otherwise, if not in want.

TABLE II.—AGGREGATE RESULTS OF AMERICAN LIFE INSURANCE COMPANIES FROM ORGANIZATION TO 1 JAN. 1917

	Ordinary	Industrial
Companies included	194	23
Policies issued	25,129,454	119,458,205
Amount issued	$50,372,022,815	$16,470,439,452
Premium receipts	$10,491,426,066	$3,077,502,361
Interest, rents, etc	3,419,706,328	449,491,110
Total receipts	$13,911,132,394	$3,526,993,471
Death claims	$3,299,977,594	$869,208,184
Endowments, annuities	994,710,950	44,437,317
Purchases, surrenders	1,475,395,177	124,380,618
Dividends	1,419,027,146	156,562,771
Paid policyholders	$7,189,110,867	$1,194,588,890

Table III is designed to exhibit the amazing growth of life insurance within the last 10 years. The pruning resulting from the 1905 investigation made by several State legislatures eliminated the false growth of tontine insurance and brought the business back more largely to its true function of life protection. All forms of endowment policies combine the element of saving with insurance, but the return to a larger use of whole-life policies shown in the table is a good symptom. It appears that, considering business companies alone, the use of life insurance in America nearly doubled in the 10 years exhibited. With

the business of 1917 added, the items for 11 years will show easily twice the amounts of 1906.

TABLE III.—AGGREGATE COMBINED RESULTS OF ORDINARY AND INDUSTRIAL BUSINESS FROM ORGANIZATION TO THE END OF 1906 AND OF 1916

	1906	1916
Companies included	138	241
Capital stock	$22,724,130	$54,764,732
Premium income	$526,594,898	$847,983,760
Interest, rents, etc	140,590,694	269,876,568
Total income	$667,185,592	$1,117,860,328
Paid policyholders	$287,325,629	$566,386,275
Expenses, etc	139,535,734	220,013,372
Total outgo	$426,861,363	$792,399,647
Assets — admitted	$2,924,253,848	$5,536,607,483
— not admitted	26,479,236	30,724,057
Liabilities	2,557,049,863	4,966,580,921
Surplus	367,203,985	570,026,562
Insurance in force — Whole life	$7,374,135,263	$13,582,986,343
Insurance in force — Endowment	2,918,489,140	3,914,915,117
Insurance in force — Other	960,569,674	2,370,368,965
Total	$11,253,194,077	$19,868,270,425

Table IV gives the aggregate results for the year 1916 and the financial standing on 1 Jan. 1917, of ordinary, industrial and assessment and fraternal business separately. The item of death claims shows that over $350,000,000 were paid to dependents during 1916, and over $300,000,000 returned to policyholders in one form or another. The other items, particularly the assets, liabilities and surplus, exhibit the strength of the life insurance as an institution. This vast scheme for the protection of human life and its interests is bound to have a tremendously increasing influence. It is something very modern and illustrates better than any other element of progress how modern civilization has broken away from the ancient grip of fate and circumstance and dared to forestall the hazards of life — and to cheat even death of its economic disaster.

CHARLES MAAR,
Insurance Department, State of New York.

TABLE IV.—AGGREGATE RESULTS OF AMERICAN LIFE INSURANCE COMPANIES FOR 1916

	Ordinary	Industrial	Assessment and fraternal
Companies included	213	28	603
Policies in force 1 Jan. 1917	10,698,452	35,674,683	9,247,550
Amount in force 1 Jan. 1917	$19,868,270,425	$4,811,041,900	$9,519,372,376
Premium income, 1916	$572,651,985	$275,331,775	$140,585,821

Surplus	$507,100,159	$93,650,460	$221,930,260

* Sick benefits.

INSURANCE, Marine. Indemnity covering vessels and their cargoes is the most ancient form of insurance, and is found in some form as far back as the records of commerce go. If, as seems probable, the persons of mariners were in some cases also covered, marine insurance originally included all the hazards that are now separated in their wider recognition on sea and land into fire, life and casualty lines.

Marine insurance as now known and practised is a development among Western nations in connection with their commercial activities by sea which had only a limited counterpart among the nations of the East in ancient times. Before the rise of civilization in Italy and Greece, the Phœnicians at the east end of the Mediterranean Sea are found in active trade bearing the products of the continents of Africa and Asia behind them to the seacoast lands of the West as far as the British Isles.

When political and commercial power passed to Asia Minor, to the Ægean Island, to Greece and then to Rome, the same routes of trade persisted, overland from the Orient and by sea to southern and western Europe, and the control of the carriage meant wealth successively to the Greek and the Roman states. After the eclipse of the Roman Empire, trade from the East suffered decline or was diverted to the then flourishing Moslem lands of southwestern Asia and northern Africa. With the reawakening of Europe after the Crusades, the free cities of Italy came to riches and power as intermediaries of trade, but only to decline before the advance in Europe of the Turks, who blocked the ancient caravan routes and thus forced the eyes of mariners westward and brought about the discovery of the American continents. Thus also was sea traffic widened and the centres of trade and wealth shifted step by step from the Mediterranean to Spain and Portugal, the Low Countries and the northwestern coast of Europe.

There is no doubt that water-borne commerce was protected against the "perils of the sea" from very early times, as traces of some form of indemnity are found in the sea regulations of Greece and Rome as well as in the

Code of Justinian and in the port ordinances of the Italian free cities. Only in recent centuries has insurance come to such importance as to fall under general public regulations; hence the scarcity of records of the simple business arrangement that sufficed earlier.

In place of the modern policy of insurance on a ship and cargo for a sum paid over by the insured, the ancient practice was more like a silent partnership on the side of the insurer, since, for instance, the Roman patricians who shunned open relations with trade were wont to loan money privately on sea ventures at the good rate of 10 per cent on the condition of repayment if the voyage was safely accomplished, but of no return whatever if ship and cargo were lost. The principal owner, being the mariner, had the larger interest in the success of the venture, and thus the silent partner had a fair chance of profit.

In contrast with this narrow sharing of the hazard, modern marine, like all other insurance, rests on a wide distribution of loss, and the basic premium or cost is determined from the average of loss gathered from experience for each type of vessel and class of voyage and is modified by the immediate considerations and circumstances of the time, such as season of the year and state of war.

For the past 200 years the business of marine insurance has centred in the Lloyds of London, first incorporated in 1871 as an exchange for the regulation of marine underwriting after the manner of other commercial exchanges. As far back as the days of the Commonwealth, seafarers were wont to gather in the coffee houses near the London docks to fraternize and transact their business. One Edward Lloyd kept such a house and shrewdly catered to his clients by affording facilities and supplying intelligence as to shipping and mariners. In the course of time he contrived to have news from all over the world drift his way and then to establish sources of information in all the leading ports.

The first simple plan of Lloyds was for a mariner to post a slip recording his vessel, cargo and prospective voyage, and those who signed up — perhaps to the number of 50 or 100 for £50 and upward, whatever each was willing to assume on the risk — were the underwriters. More than any other branch of insurance, marine business depends on entire honor between all parties and a well-developed judgment as to shipping, trade, times and seasons. Marine underwriting judgment depends fundamentally on marine information, which Lloyds has aimed to supply most completely. Its several publications give particulars as to vessels and mariners and fullest intelligence as to their location and fortunes as they fare over the seas. Business is placed to-day largely by agents or brokers, and as they present their papers an underwriter, representing himself or a company, must be ready at short notice to decide for or against participation. There is no opportunity for particular inspection of risks. The rating of the vessel, according to age and build, and the standing of the owners and the mariner are his main reliance.

Since the first quarter of the 18th century, British joint stock companies have competed with Lloyds and now transact the larger half of the marine business done in Great Britain, and the two together carry the bulk of the world's marine insurance. The stock companies depend on Lloyds for the intelligence essential to their operations. By means of the cables, a great deal of insurance flows into London from all over the world, owing to the advantages possessed and cleverly used by the London underwriters in the way of world-wide banking and trade facilities, as well as marine intelligence. In fact, London marine underwriting has achieved a clear monopoly, so that it can afford to underbid competitors to secure patronage.

American marine insurance began in colonial times with personal, private underwriting at the several Atlantic ports, much on the early plan of Lloyds. Under the rigid laws of the mother country, the larger traffic was confined to English bottoms, which as always loyally carried English insurance, but a lively coastwise and West India trade existed in America up to the Revolution and men of means were to be found in every port able and willing to finance and underwrite adventures on the sea, as such trade was profitable enough to yield an ample return for all concerned.

The War for Independence increased the hazard of traffic by sea sufficiently to cut off the form of private insurance that was in practice, but the opportunities for privateering more than compensated the extra risk for the bolder American mariners. As commerce began to revive under the new national life inspired by the adoption of the Constitution in 1789, the demands of a world trade that opened to American shipping with its unlimited supply of shipbuilding timber, called for an amount of security that could be met only by organized capital. Attempts to copy London Lloyds at several times failed. Our long seaboard, the lack of communication and the separate interests of the States did not afford the unity of action needed to promote success.

Hardly was American marine insurance thus started in a larger way, when the Napoleonic wars worked it disaster. During the winter of 1793–94 about 600 American vessels were seized and detained in British ports, lest our mariners should supply the enemy French with necessities. It took the better part of a year and sometimes years to get news and to make settlements, and the companies waited long years for a settlement of their consequent claims against government. This vexatious state of affairs continued in spite of protest and threat of war and the War of 1812 brought no better security to American shipping. Between 1803 and 1812 nearly 1,600 American vessels were captured by British, French and other European powers.

The American marine made a slow recovery after the settlement of European peace in 1815, but from 1830 to 1860 enjoyed a large growth. This was the era of the clipper ships, when the American sails and sailors outsped all competitors. Vessels left our ports in numbers even for the Far East. Importing firms owned their craft and sent their representatives to dispose of the cargo and to buy for the return trip the silks, tea, coffee, spices and other products of China, Japan and India. The voyage took many months. Insurance rates were necessarily high, but the business was uniformly placed with American companies and marine business prospered with the prosperity of the importer.

The Civil War demoralized a large American oversea trade and American marine insurance shared the disaster. The national energies were called home and such traffic as still ventured forth was liable to fall victim to Confederate raiders that were fitted out in Europe. While the conflict was on between North and South, the change from wood to iron construction and from sail to steam-power went on apace. When American trade was able to look out again upon the sea, after the close of the war, British shipping everywhere had the advantage in speed and capacity and the Lloyds of London clinched the situation by means of its power to make ratings, to supply quick intelligence and to afford political and financial backing to its clients.

Insurance, like trade, follows the flag. The vicissitudes of the American marine and of American marine insurance may be appreciated from the fact that the registered tonnage increased from 762,838 tons in 1840 to 2,496,894 in 1861, and declined so as to rise only to 888,624 in 1904. Lloyds Register of 1 July 1915 showed that all American vessels, steam and sail, including those of the Great Lakes and the island possessions, numbered 3,249 and the tonnage 5,892,638. This was about 28 per cent of the British, while the British then had one-quarter of the world's shipping and one-third of the world's tonnage.

The superior advantages possessed and used by British marine insurance companies, in conjunction with British shipping and banking, was demonstrated after 1870, when they began to establish American branches. Under our laws they entered the States to do business under easier conditions than domestic companies enjoyed. By vigorous rate cutting the foreigners made such inroads upon the natives that many of the latter were soon compelled to abandon the field. As shown in the accompanying Table I, the 72 native companies doing marine business in 1870 dwindled to 47 by 1880, and during the same period 11 foreign corporations entered the American field. The number of native companies doing marine business had decreased to 20 by 1905, but since then has steadily increased with the increase in importance of American shipping. The number of foreign companies has also steadily increased and they have done and still do not only the larger proportion, but also the more profitable part of American marine insurance. In 1918 New York had 108 fire and marine companies doing marine business.

Marine business cannot be reported fully as considerable American shipping is covered by Lloyds and foreign companies writing directly and therefore making no returns. No complete statistics are available and such returns as exist include inland navigation and certain automobile coverage; still the companies authorized in New York State do the great bulk of American marine business and the showing made in Table I gives a fair idea of the growth and importance of this line of insurance. The years covering the period of the European War reflect the rising shipping values and premium rates occasioned by the commerce raiding of the first year and the submarine warfare of the subsequent years; and reveal also a substantial increase of marine business placed in America. The figures for the Federal war risks on shipping are not available and must be added to exhibit the whole increase.

Table II exhibits the large increase of premium receipts, since the opening of the Great War, of the marine companies authorized in New York, which however do a small amount of inland and motor vehicle business. The amounts should, it is said, be increased by a third for unreported business. During the first two years given the foreign companies did one-third, and during the last two years nearly three-fourths, of the business.

TABLE II.—PREMIUM RECEIPTS OF MARINE COMPANIES AUTHORIZED IN NEW YORK STATE

YEAR	Amount
1914	$38,752,353
1915	53,838,772
1916	76,961,727
1917	119,987,416

As the Civil War threw American ocean trade into European hands, so the World War seems destined to give American shipping an opportunity to recover itself and acquire a proper share of the world's carrying trade. Future American prosperity will depend vitally on commerce, and commerce depends on an intimate alliance of shipping, banking and insurance for the foreign market. Henceforth the world will be organized internationally and America must prepare the instruments for international trade, of which marine insurance is one of the most important, since a foreign monopoly in this can and will inevitably make our ocean shipping and trading unprofitable.

Books are available in libraries to those who wish to learn particulars as to policies

TABLE I.— MARINE AND INLAND NAVIGATION BUSINESS OF ALL INSURANCE COMPANIES AUTHORIZED IN NEW YORK STATE

YEAR	Number of companies: American	Number of companies: Foreign	Risks written	Premiums received	Losses paid
1870	72	.....	$1,330,250,786	$16,300,621	$7,046,097
1880	47	11	1,906,475,177	16,954,195	9,277,853
1890	40	16	2,636,614,231	16,767,993	6,874,333
1900	24	15	5,226,446,147	18,587,451	7,132,179
1905	20	21	5,689,771,934	23,469,212	9,073,592
1910	23	22	12,595,997,689	46,515,014	13,062,156
1911	28	26	13,425,879,616	49,887,214	12,301,865
1912	31	30	15,781,957,187	59,716,335	15,372,153
1913	35	32	16,174,370,673	63,521,450	19,005,239
1914	38	33	16,686,909,623	70,962,392	19,471,413
1915	48	37	21,526,601,714	101,538,966	26,452,956

and rates, and the intricacies of marine transactions and loss settlements, as also the history of marine insurance development.

CHARLES MAAR,
Insurance Department, State of New York.

INSURANCE, Old Age. See OLD AGE INSURANCE.

INSURANCE, Science and Economics of. Insurance, to-day, forms an integral element of our social and commercial life. From crude beginnings, the principle of providing, by the contributions of the many to a common fund against the financial consequences of individual losses due to the inherent uncertainties in human affairs, has been perfected until the modern practice of insurance includes all the more important contingencies affecting human welfare. In both science and economics insurance holds a most important position, which becomes more readily apparent as the practice and results of the business are inquired into and considered in their relation to individual and national well-being. As a business insurance holds rank as one of the foremost enterprises of the age, equal in importance to banking and transportation. It would, without exaggerating, be as difficult to think of commerce without insurance as of transportation without railroads or the transmission of intelligence without the telegraph. Modern life has become so completely interwoven with the idea of insurance that there are few contingencies affecting life and property to which the principle of insurance has not been more or less successfully applied.

The scientific basis of insurance is the same in all its branches, that is, the laws of chance and probability. In considering any future event we are confronted by the uncertainty whether such an event will or will not happen, but from the facts of experience upon a large scale it is now possible to calculate with sufficient accuracy the monetary equivalent required to meet the risk assumed by an insurance company. The recognition of insurance as a science dates from 1747, when Corbyn Morris published his classical 'Essay Toward Illustrating the Science of Insurance,' wherein he attempted to "fix by precise calculations several important maxims upon this subject." Accuracy and precision is the essence of all scientific method which in its practical application to insurance does not differ in any important essential from the method which underlies all other scientific processes. The larger the mass of facts considered, the more definite must be the resulting conclusions, which for practical purposes are the equivalent of natural laws and confirmed by subsequent experience verifying the truth of the theory assumed.

Insurance science has thus far found its chief development in the department of life contingencies, due, no doubt, to the fact that the average duration of human life and its pecuniary value require to be determined with the greatest possible accuracy, since the contracts made dependent thereon extend, as a rule, over many years. In other forms of insurance, such as fire, marine and accident, the contracts are generally for short periods, seldom of longer duration than a single year. Hence most of the scientific discussions and the numerous dissertations upon the subject relate chiefly to life contingencies, but there has been a decided improvement in this direction during recent years. The deliberations of associations of actuaries and insurance managers extending over many years, in particular the Institute of Actuaries of Great Britain, are fully entitled to rank, in thoroughness of research and grasp of fundamental principles, with the deliberations of other scientific bodies. It is, no doubt, due to this fact that insurance was included in the most recent classification of the sciences as represented at the International Congress of Arts and Science at Saint Louis, held in connection with the exposition of 1904.

Insurance as a science is a branch of economics, although only a few of the more recent writers on the subject have given careful attention to the theory of risk and insurance in its relation to public welfare. A fairly complete explanation of the economic theory of insurance is to be found in an essay by Allan H. Willett, published by Columbia University in 1901. He holds, and very properly so, that "as a general rule uncertainty exercises a repellent influence in human life, and the existence of risk in an approximate static state causes an economic loss, while (on the other hand) the assumption of risk is a source of gain to society." From this point of view the business of insurance does not differ essentially from general commercial enterprises. Risk is assumed in mining and agriculture in much the same manner as risk is assumed in the business of insurance, but in life insurance, for illustration, the assumption of a risk and the equivalent premium payments required are determined by the theory of probability and the established laws of human mortality and observed experience. In general commercial enterprise the risk assumed is, as a rule, created, while in insurance the risk is pre-existing. This marks the broad division between gambling and insurance. Insurance is not "in the nature of a bet," for in insurance an effort is made to eliminate an existing individual risk by its assumption on the part of the many, while in gambling a non-existing risk is created with resulting uncertainty and needless loss to society.

Insurance companies are chartered institutions with their powers of existence and rights of transacting business derived from the State. They are subject to supervision by special departments in charge of commissioners or superintendents of insurance, who have ample power to inquire into every important detail of office administration. At first the burdens of State supervision were light, since the companies transacted but little business outside of their home State, but within the last generation the business operations of most of the companies have of necessity been extended to other States and Territories. There has, as a result, been developed a vast system of over-supervision, accompanied by an immense amount of over-legislation, much of which is inimical to the highest and broadest development of the business. The position of the commissioner is, as a rule, a political one, subject to the changing fortunes of the parties, and new men have frequently come forward with radical ideas, which, if carried to the extreme, would have

resulted disastrously to the companies and their policyholders. It has been very ably pointed out by Senator John F. Dryden, in an address on 'The Regulation of Insurance by Congress,' that "Insurance is to-day a universal institution reaching all classes and affecting more or less all commercial interests. It is an essential element of human progress and a method and means for the uplifting of the masses to a higher level of economic security. It has become national in character, and few companies confine their operations to a single State; in fact, if operations were so limited they might prove disastrous and make the conduct of the business impossible."

The taxation of insurance is a difficult problem and a matter of serious concern to the companies. In its final analysis the incidence of insurance taxation falls upon the policyholders and the cost of insurance is correspondingly increased. The fact is overlooked that insurance itself is in the nature of a tax and that additional tax burdens are a needless hindrance to the largest development of the business. In 1914 life insurance alone paid in taxes, fees, etc., not far from $16,000,000 and the proportion of taxes to income is constantly increasing, due to additional burdens placed upon the companies as a convenient source of public revenue. A tax upon premiums is an unjust burden upon the business, and is both inexcusable and unscientific. This tax falls alike upon new premiums for risks just incurred and upon renewal premiums upon risks assumed years ago. Since risks assumed years ago were calculated to produce a certain result on the assumption of a known mortality and 4 per cent interest, taxes upon premium payments must necessarily and considerably decrease the returns to participating policyholders, and increase, in consequence, the cost of insurance. If carried to the extreme, especially in the case of companies which issue only non-participating policies, it is possible that the companies may ultimately be unable to meet their obligations in consequence of a policy on the part of the State which is as unwise as it is unnecessary.

Insurance by government is not a new proposition, but it is only during the last half century that there has been an effective effort to establish an insurance department by government in active competition with private companies. In life insurance the experiments of England and New Zealand are the most valuable because the results are, on the whole, fairly comparable with those of non-governmental institutions. Post-office life insurance in England was established in 1864, and the Life Insurance Department of New Zealand in 1869. The former employs no agents or solicitors, while the latter, in all essentials conforms to the methods and usages of private companies. The premium rates and the results to policyholders have been about the same, averaging fairly with those of regular companies of good standing. The business results in England have been insignificant, while in New Zealand a fair measure of success has been achieved. In New Zealand at best and at most, the results have not been better, the cost has not been lower and the security has not been superior to that offered by private institutions, which have increased their business in force at the rate of 82 per cent during the period 1902–12, against an increase of 20 per cent for the government department. The private companies are gradually gaining on the government, and while in 1894 49 per cent of the total policies in force were with the government, in 1912 the proportion was only 34 per cent. To those who believe that the government which governs best is the government which governs least, and that the limit of state duties is unduly enlarged by state trading in such directions as these, the New Zealand experiment is conclusive evidence that government effort in the field of life insurance is not likely to produce results superior to those which have made commercial life insurance the most successful business of the age.

As distinct from voluntary insurance by government or private companies, the so-called system of compulsory insurance for workmen holds a unique and important place in the social economy of certain European nations, particularly Germany. The term compulsory insurance is seriously misleading, for, as a matter of fact, the system is not insurance at all, but a state provision for workmen against the financial consequences of accidents, sickness, invalidity and old age. In its inception the German system of government insurance was a measure designed to counteract the socialistic tendency in opposition to the monarchy. In its development it has been made to include nearly the entire body of workmen and as a theory of government and social reform it has unusual attractions. Critically examined, the system is little else than poor relief under another name, and inadequate in many respects as all methods of compulsory thrift must necessarily be. It is insurance in name, but not in fact, for it is not by the sole contributions of the beneficiaries that the required funds are provided, but by the joint and compulsory payments of employer and employee, plus a state subsidy or grant from the general revenue raised by taxation. The evidence as to the economic and social results of this system is so involved and conflicting and subject to such different interpretations that no final conclusion for or against the system can be advanced at the present time. This much, however, it is safe to say, that the anticipated benefits have not materialized, and the socialistic agitation, although much modified and of a somewhat different character, is to-day more pronounced in Germany than ever before. Nor has compulsory insurance solved the labor problem and brought about a substantial improvement in the relation of capital and labor. The most serious economic aspect is the burden of the system upon German industry and the resulting handicap upon competition in international trade. In the opinion of Professor Farnam of Yale, an impartial student of the subject, "the supporters of the German system are claiming for it more than the facts of the case as they now stand warrant," and that "The German experience with this kind of insurance seems to show that, while it is possible with a highly trained intelligent administration to carry through a scheme which will compel provision against various contingencies, it has thus far been impossible to create the instinct of forethought and care which is implied where insurance is voluntary. There are many facts which go to create a strong presumption that the result of this governmental care is actually to make people less careful of

the future, and less judicious in their expenditure.»

Insurance had its origin in private enterprise and it has attained its commanding position as a world force for the betterment of the social condition of mankind through the initiative, ability and courage of a group of men as much deserving of immortal fame and glory as any other class of benefactors of the human race. State trading in the field of insurance has never advanced the cause by a single important innovation or by a new theory or by a material improvement in practice. The necessary reforms and changes as dictated by experience have been brought about by the companies and it is due to these and these alone that the insurance business has become one of colossal magnitude and world-wide extent.

The World's Insurance Congress of 1915, held in San Francisco in connection with the Panama-Pacific International Exposition, proved a memorable event in the annals of insurance in all its branches, and foreshadowed broader national and international conceptions of the business which now ranks foremost among the institutions making for human betterment. The essential facts and phases of insurance as a social and economic institution were presented by eminent members of the insurance profession. Among the addresses were «The Service Performed by Fire Insurance Companies,» «The Force of Insurance in Social Economy,» «Insurance and Conservation of Human Life.»

No other business so completely enjoys public confidence and has so successfully stood the test of long experience. As the scientific principles of insurance are examined and the highly specialized administration of the companies is considered and the results are measured by a fair standard of benefits in proportion to cost, the verdict of science and economics will agree with that of the mass of mankind that our social and commercial progress would have been impossible without insurance. Resting upon this broad foundation of human experience and public confidence, the colossal business of modern insurance challenges the admiration of the world.

Bibliography.— Insurance has a literature of its own and a most interesting history extending over more than four centuries, with suggestions of at least a conception of the insurance idea among the most ancient people of whom there is a recorded history. The limitations of this article preclude more than a brief reference to the more recently published works, among which may be mentioned Willett, 'Economic Theory of Risk and Insurance' (New York 1901); the 'Yale Insurance Lectures' (2 vols., New York 1904); Alexander, 'The Life Insurance Company' (New York 1905); Young, 'Insurance' (London); Dean, 'Fire Rating as a Science' (Chicago 1901); Phelps, 'History of American Insurance During the Last Decade' (*American Underwriter,* New York 1904); Vance, 'Handbook of the Law of Insurance' (Saint Paul, Minn., 1904); Wolfe, 'Investments of Insurance Companies' (New York 1905); Hoffman, 'Insurance Science and Economics' (New York 1911); Dunham, 'The Business of Insurance' (New York 1912). These are but a few of the many books on insurance which have been published during recent years. In addition there are the insurance yearbooks on life, fire and miscellaneous insurance, the annual reports of insurance commissioners, some of which contain critical observations on insurance problems of the day, the annual proceedings of underwriters' associations, and the national conventions of insurance commissioners, the special publications of insurance companies, their histories, etc., the discussions on State supervision and Federal regulation of insurance, of which the two more important are an address by John F. Dryden, president of the Prudential Insurance Company of America (1904), and a report of the Committee of the American Bar Association on Insurance, by Ralph W. Breckenridge, chairman, Omaha, Neb. (1905). But the chief source of information regarding insurance practice, the progress of the business, the organization of companies, etc., is to be found in the technical and general insurance periodicals, the *Insurance Monitor, The Spectator,* the *Weekly Underwriter* and the *Insurance Press* of New York, the *Baltimore Underwriter,* of Baltimore, the *Standard,* of Boston, the *Economic World,* New York, and many others.

FREDERICK L. HOFFMAN.
Third Vice-President and Statistician of the Prudential Insurance Company of America.

INSURANCE LAW. A body of statutes controlling the business of insurance has grown with the growth of insurance in modern times in all civilized lands. As an element of trade, insurance necessarily came under certain regulations from its earliest use, and with its expansion from local to national and international proportions and from almost private utility to a general social and commercial necessity, public control has increased to cover almost every detail of the business.

The insurance of vessels and their cargoes at sea was the earliest line to attain importance, and the practice of individual owners sharing losses seems to have been an ancient one. Naturally certain customs and ordinances covering these transactions came first to be recognized and established at the larger seaports. Before the fall of Constantinople in 1453, the world-trade routes lay east and west from the great seaports of the Mediterranean Sea,— Florence, Venice and Genoa. The traffic east was by land, and west by sea. When the conquering Turks shut off the overland traffic east, it became necessary to search out another route, with the resulting discovery of the way around the southern point of Africa by the Portuguese and of a new western world by Columbus. The seaports of Portugal, Spain and the Netherlands now became busy distributing centres of trade from the Far East and West to north and and central Europe. The longer sea voyages made desirable a better security against loss, and this involved more government regulation.

In the 14th century, when trade flourished at the ports of Italy, of the Spanish Peninsula and at Bruges in Flanders, the practice of sharing losses among the interested individual owners called forth simple ordinances to define the practice and to outline the necessary agreement or policy form. In more recent times the trade centres of Europe have drifted largely to northern Europe, but in the London Lloyds is found the ancient practice of individuals, under certain regulations, underwriting sea risks to the largest amounts. Since the opening of the 19th century, however, there have come into being corporations which underwrite marine contracts as a business venture on the basis of average loss, such as now underlies all other forms of insurance, and both the world's increasing need and the formation of purely business companies to meet the need for the protection of water-borne commerce have made necessary a larger public control of marine insurance.

In America a similar development occurred to that in the Old World. As the sea trade of the northern-eastern Atlantic ports sprang up, during the later colonial period, interested individuals shared the risk of the traffic as interinsurers, until at length the expanding need of the independent States of the Union called for the larger service of capitalized companies, through which the business of insurance was more and more brought into the purview of law.

Meantime the demand arose also for other forms of protection,— insurance against the hazard of fire, and death, and more recently against sickness, accident and the numerous other hazards commonly grouped as casualty insurance. The great London fire of 1666 emphasized the necessity for insurance against fire and shortly after the beginnings of fire insurance the first forms of modern life insurance began to appear.

In each case, individual sharing of losses, or the principle of mutuality, was brought into use, but eventually each line has come to extensive application under organizations of joint-stock corporations, although in America life insurance is transacted mostly by companies without capital stock. Public regulation was at first concerned with the term of the contract, called a policy, but with the expansion of the service came the necessity for securing the integrity of the corporate insurer by regulations covering the investment of its funds and providing for an adequate reserve against future obligations.

The first legal restraint, under British regulation, was one designed to check a tendency to gamble on marine risks, resulting in the establishment of the principle of insurable interest. Experience and study combined to furnish a scientific foundation for insurance during the 18th and 19th centuries in the matter of adequate premiums and reserves, and during the latter century the competition of numerous small companies tended to develop business and to find new fields for its application, so that to-day insurance enters every part of our commercial and social structure.

When the business of insurance was largely local, public opinion influenced its control, but with the later growth of companies extending their operations over wide areas, it became necessary to define closely by statute all the conditions, in order to secure equitable treatment to the insured and to conserve the funds necessary to meet future obligations. As the result of public control this far, there has emerged a decided tendency to uniform standards, methods and requirements that may in the end develop a uniform code of insurance in the United States, where now 52 diverse local codes have often hampered the transaction of interstate insurance by varied and conflicting or duplicative requirements.

The present State laws covering the essentials of insurance organization, methods of business and standards of solvency have, under the pressure of business demand, become so much the same that a development toward Federal control of interstate insurance would naturally follow an acceptance of such insurance as an element or instrument of commerce. This is asserted by insurance leaders to be in line of progress and would open the way for a Federal code that would serve as a model to all the States and Territories.

The entry into the United States of a large number of foreign companies, during recent years, will likewise tend to bring interstate insurance under national control. At the present time nearly 100 such corporations are doing business in New York. Matters relating to American companies abroad and to national supervision found place in President Cleveland's second and third messages, and in President Roosevelt's fourth and fifth messages. Shortly after the declaration of war against Germany in 1917 the Federal government took charge of the business of all enemy corporations in the United States.

American laws recognize uniformly the practice of rigid separation of fire, or combined fire and marine, from life, health and accident insurance, and both from the general casualty lines, and require separate organizations for their transaction, herein differing from practice in Europe, where several lines may be covered by one company, though usually with a separation of funds.

CHARLES MAAR.

INSURANCE PATROL, also known as fire patrol, protective department and salvage corps, is an organization now existing in all the larger cities under the support and control of local boards of underwriters but closely associated with fire departments, with the object of protecting property from theft and damage during a fire. They operate mostly in business districts and are now generally equipped with high power motors carrying fire extinguishers and waterproof coverings, the latter to be used to protect merchandise and furniture in cases where removal may be impossible or unnecessary.

This service has grown from small beginnings and has been the means of largely reducing losses for the supporting companies. In New York city, as early as 1835, the associated fire companies employed four men at the yearly salary of $250 each. This city's force now consists of nearly 200, divided into seven companies. The Chicago patrol has a chemical engine and eight companies. Boston began in 1849 with six oiled covers and now has three well-equipped companies.

A valuable incidental service is performed by the patrols in investigating the origin of fires and their reports afford an accurate basis for underwriting statistics. In 1892 a national association of superintendents and captains was formed to promote friendly relations and

gather statistics. Yearly conventions have since been held.

CHARLES MAAR.

INSURANCE SUPERVISION. While insurance was mostly concerned with marine risks little public regulation was required, as each transaction was completed in the course of a few months, or about a year at most, and the practice of interinsurance between owners required no accumulation of funds. With the advent of fire insurance after the Great London conflagation of 1666 and the beginnings of life insurance a generation later, the conditions of insurance as a business became more complex and the accumulation and security of funds necessary. All insurance is based on average loss as shown by experience, but a policy of fire or life insurance may remain in force for a series of years. Public supervision has concerned itself, on the one hand, with the terms of the policy contract to secure fairness and equity, and, on the other hand, with the business integrity of the insurer; and the intimate oversight of all forms of insurance is justified by the fact — not at first realized, but now universally admitted — that the insurer acts in a fiduciary capacity toward the multitude of its policyholders.

In recent years, with the application of insurance to a multitude of business relations, covering many hazards of persons and property, it has come to pass that the world's commerce and trade and the welfare of society depend vitally on insurance as an arch depends on its keystone. A truly tremendous responsibility, therefore, has come to rest upon supervisory officials.

Owing to the local nature of early insurance and the provision for local incorporation when corporate insurance began, State supervision came into being. Before the middle of the 19th century the interests involved called for little more than a yearly financial statement, but by the end of this period an era of rapid growth and vigorous speculation in insurance as a business set in. The increasing interests and erratic tendencies combined to demand closer and more special public inspection. A department of insurance was created in Massachusetts in 1855 and under the direction of Elizur Wright, a genius in insurance science, developed great efficiency and set high standards. The same can be said of the New York department, organized in 1860 under the guidance of William Barnes, Sr. Connecticut and Indiana established insurance departments in 1865, California in 1868 and Missouri in 1869. Gradually all the States have assumed a measure of supervision over the insurance business within their separate borders, in some cases at the hands of one of the regular State officials, but most generally by means of a specially appointed superintendent or commissioner.

Although the insurance business in all lines has long since become national and even international in its scope, supervision has remained localized in the States under the influence of a number of decisions of the United States Supreme Court adverse to insurance being an element or instrument of commerce, which precludes Federal oversight. The first case bearing on this point, Paul vs. Virginia, was decided in 1868. Classes of fire, life, accident and health companies or societies doing a local business must necessarily remain under State supervision, but there is no longer room to doubt that the corporations doing interstate business could be much more economically and efficiently supervised by the national government. To accomplish this desideratum in the face of the decisions mentioned, an amendment to the national Constitution is necessary.

The possibility of conflicting authority among the 52 insurance departments in the United States has been obviated to a large degree by the influence of the older States in establishing methods and standards and also by the yearly conference of officials which began in 1870 in the National Convention of Insurance Commissioners. This body has been the means of unifying opinion and of securing the adoption of uniform financial statement blanks and standard policy forms or conditions, as also uniform laws covering certain phases of insurance, such as fraternal orders, casualty reserves and standards of solvency. It is perhaps too much to hope for a uniform insurance code as the final outcome, but some degree of Federal supervision is a near possibility and this will produce an immense saving of expense by eliminating the varied and duplicative requirements of the local authorities on interstate insurance.

The cost of supervision is made a charge upon insurance companies in the form of fees and taxes, which have come so far to exceed expense requirements as to constitute a substantial source of State revenue. This charge ultimately falls upon the policyholders and is criticised as a tax on thrift. The contention that insurance of every form is such a social and economic necessity as to deserve encouragement, rather than made a source of revenue, would appear just.

CHARLES MAAR.

INSURANCE TAX, a levy under the War Revenue Law which became effective 1 Nov. 1917, whereby individuals or corporations issuing insurance policies are required to pay within the first 15 days of each month on (a) life insurance, except reinsurance, eight cents per $100 of policy; (b) life insurance policies of $500 or less issued on weekly payment plan, 40 per cent of the first weekly premium; (c) fire, casualty, liability and all other insurance and renewals, except reinsurance, one cent on each $1 of premium. For general taxation of insurance, see INSURANCE, SCIENCE AND ECONOMICS OF.

INSURANCE TERMS in general use in the transaction of life and marine insurance business:

ABANDONMENT.— A term used in marine insurance to denote that all property saved has been relinquished to the underwriters in order that the insured may claim indemnification for a total loss.

ABORDAGE.— A term used in marine insurance. If a collision between two vessels happens on the open sea and the damaged ship was insured the persons insuring her must pay the loss, although they are entitled to relief at civil law against the party causing the damage.

ACCEPTANCE.— A term usually used, in marine insurance, in cases of abandonment. It is this process which perfects the rights of the insured in the recovery of his loss.

ACTUARY.— An officer of an insurance company whose skill in the application of the doctrine of chance to financial affairs enables him to make the computations necessary to determine the valuation of contingent liabilities, as shown in the compilation of tables, the computation of risks, etc.

AGREEMENT.— In insurance the contract issued prior to the delivery of the official policy is known as the "agreement."

ANNUITY.— A fixed amount paid each year, whether in one sum, or periodically, in instalments. When an annuity is continued for a specific number of years it is termed a "certain" annuity. If the period of its continuance is uncertain it is called a "contingent" annuity. When payment has already commenced it is an "annuity in possession," but when such payment does not begin until a specified period has elapsed, or a definite event has taken place it becomes known as a "reversionary" or "deferred" annuity.

ASSESSMENT.— In insurance, an assessment is made (1) as an apportionment in general average upon the articles at risk for contribution for damage and sacrifices purposely made for escape from impending peril, and (2) also upon premium notes given by members of mutual companies as a substitute for the investment of the paid-up stock.

AVERAGE BOND.— A bond in marine insurance under which the consignees of cargo subject to general average guarantee payment of their contribution as soon as ascertained in order that their goods may be delivered at once.

BARRATRY.—In marine insurance, the commission of any fraudulent act in the management of a ship, or its cargo, by which the owners, consignors or insurers are subject to injury.

CASUALTY.— A term frequently used in insurance as a synonym for accident.

COINSURANCE.— A form of insurance in which the insured, in view of a reduced rate of premium, agrees to maintain insurance upon a certain specified percentage of the total value of his property, failing which he becomes his own insurer for the difference, a fact which makes him jointly responsible with the assuring company in case of partial loss.

CONSTRUCTIVE TOTAL LOSS.— A term used in marine insurance when the thing insured and damaged, while not entirely a total loss, is so nearly so that it is practically beyond recovery or repair. In such cases a notice of abandonment is served upon the insurers by the owners, after which the "constructive total loss" may be recovered.

DECREMENT.— A term used in insurance, usually in the sense of the "equal decrement of life," or the doctrine of annuities upon which assurance companies base their existence. It is the theory that in a given number of lives there should be an equal number of deaths within a given period.

DEFERRED INSURANCE.— A form in which the liability of the company does not begin until a certain specified date in the future.

DEVIATION.— A term used in marine insurance to denote the voluntary departure of a vessel, without necessity or reasonable cause, from the usual course of the voyage for which she was insured. All unreasonable delays are also involved in the same law, which releases the underwriter from all risks.

DOUBLE INSURANCE.— A term used among insurance companies as a synonym for over-insurance. Thus, where divers insurances are made upon the same interests against the same risks in favor of the same assured, in proportions exceeding the value of the subject, the party insured may sue upon all the policies although he is entitled to but one satisfaction.

ENDOWMENT.— A term used in life insurance to describe a policy in which the face value, with accrued earnings, is payable to the insured at, or after a stated period, or in which the face of the policy is paid to his representatives should he die prior to the expiration of that time.

FLOATING POLICY.— In marine insurance a policy covering certain interests wherever located, even in vessels unknown to the insured or the insurer.

GRAVEYARD INSURANCE.— A term used to designate a method of swindling insurance companies by the substitution of a person of robust health for the bad risk actually insured. Also used to describe other kinds of insurance swindling, or crimes committed in the collection of insurance moneys.

INSURABLE INTEREST.— It is essential to the insurance contract that the insured should have a legal interest in the object for which the insurance was taken. In France the laws annul all policies that exceed the insurable interest of the assured at the time of the subscription.

INSURANCE.— A term used to describe a contract whereby for an agreed premium one party undertakes to compensate another party for loss in a specified subject by specified perils. There are several kinds of insurance companies in operation, but nearly all are either "stock" or "mutual" companies, while the risks covered include, life, accident, fire, health, marine, burglary, live-stock, plate-glass, etc.

JOINT-LIFE POLICY.— A policy issued to husband and wife payable to the survivor upon the death of either. The husband is required to show that he has an insurable interest in the life of the wife. This policy is of special utility in cases where either husband or wife possesses a life interest in property or funds.

LOSS, AMOUNT OF.— An insurance term denoting the diminution or destruction of the values of, or of the charge upon, the insured by the direct consequence of the operation of the risk incurred, according to its value in the policy. See TOTAL LOSS.

OPEN POLICY.— In insurance, a policy in which the value of the subject insured has not been fixed, but has been left to be determined in case of loss, or because it has been left open to permit of the addition of other things whenever occasion demands.

PARTNERSHIP POLICY.— One issued to a firm in which each of the partners is insured for the amount of his capital which is thus safeguarded for the use of the firm in case of the death of the insured.

SURRENDER.— A term in insurance to denote that the party insured has abandoned all right in his policy in consideration of having received a portion of the premiums already paid to the company. The percentage of premiums returned is known as the "surrender value" of the policy.

TERM INSURANCE.— That issued for a given period to cover a particular or extra risk.

TIME POLICY.— A form of marine insurance covering vessel or cargo, or both, for a specified time only.

TONTINE POLICY.— In insurance, a policy in which the insured agrees that no money shall be received by him from the insuring party, either in the form of dividends, return-premiums, or surrender-value, for a specified term of years, but that, instead, the entire surplus shall be permitted to accumulate until the end of that period when it may be divided between those who have kept their policy in force.

TOTAL LOSS.— In marine insurance, total loss may mean that the subject insured has been absolutely destroyed by the peril against which it was protected, or it may mean that the loss by damage, seizure or other causes has been so great as to be practically absolute. In the latter case it is often termed a "constructive total loss."

VALUED POLICY.— A term used in insurance to show that a policy is one in which the value has already been set upon the subject insured, the insertion of which fact in the policy, with the amount agreed upon, makes proof of damages in case of loss unnecessary.

VOYAGE INSURANCE.— That covering goods or vessel only during the specified voyage from one designated port to another.

WAGER POLICY.— In insurance, a policy in which the insured has no insurable interest, and, being generally regarded as a form of gambling, such policies are not valid except in places where the validity of a wager may be recognized.

INSURRECTION, the act of rising against governmental authorities, active opposition to the power of the State. In the United States, power to suppress insurrections by employing the militia is given to Congress by the Constitution, Art. I, Sec. 8, Clause 15. In 1792 and 1807 acts were passed giving the President power to call forth the militia when notified by an associate justice of the Supreme Court or a district judge that the execution of the laws is obstructed, and on application of a legislature or a governor, when the legislature could not be convened, and to employ also the land and naval forces of the United States. The Whisky Insurrection (q.v.) was directed against the Federal authority and the President employed force to suppress it on notification by the Federal judge. During the Buckshot War (q.v.), in 1838, between the Whigs and Democrats in Pennsylvania, the governor of that State asked for assistance, but it was refused. The governor of Rhode Island made a similar application during the Dorr Rebellion (q.v.) and the regulars were held ready for action, but their aid proved unnecessary. These last two cases came under Art. IV, Sec. 4, of the Federal Constitution, which provides "that the United States shall protect" each State on application of the legislature, or of the executive, against domestic violence.

When the Civil War began the President was obliged to take prompt steps in calling out the militia, though no application had been made to him as required by the acts of 1792 and 1795. His action was justified by Art. II, Sec. 3, of the Constitution, providing that "he shall take care that the laws be faithfully executed," but Congress on 6 Aug. 1861 formally validated

and made legal all of President Lincoln's previous acts, proclamations and orders. The Force Bill (q.v.) of 20 April 1871 gave the President special power to use military force in certain contingencies. In the South during the reconstruction period, and in the North, during strike riots, Federal troops have been used.

INTAGLIO, a method of cutting a stone or gem by which the design is cut or hollowed out—not raised, as in a cameo. In art, the term means the opposite of relief, denoting the representation of a subject by hollowing out a gem or other substance; so that an impression from the engraving has the appearance of a bas-relief. Intaglio letters have been effectively used in printing in recent years, and much of the effectiveness of colored printing is due in large measure to a process or processes closely akin to intaglio.

INTEGRAL CALCULUS, a branch of infinitesimal calculus, treating of the methods of deducing relations between *finite* values of variables from given relations between contemporaneous infinitesimal elements of those variables. It is thus the inverse of the differential calculus. Its object is to discover the primitive function from which a given differential coefficient has been derived. This primitive function is called the integral of the proposed differential coefficient, and is obtained by the application of the different principles established in finding differential coefficients and by various transformations. To illustrate—with the integral calculus one may discover the relations connecting finite values of variables, as x and y, from the relation connecting their differentials, as dx and dy. Integral calculus is thus the doctrine of the limit of the sum of infinitesimals of which the number increases, while the magnitude decreases, both without limit, yet according to some law. The more proper concern of the integral calculus is besides the finding and discussion of integrals, with such matters as the theory of spherical harmonics, the theory of residuation, and parts of the theory of functions. The sign of integration is "f," which is a form derived from the old or long "s." It is the initial of the word "sum," and came into use owing to the conception that integration is the process of summing an infinite series of infinitesimals. Before even the notation of the differential calculus and its rules were discovered by Gottfried Wilhelm von Leibnitz (1646–1716), he had invented the notation and had found some of the rules of the integral calculus. Leibnitz first used the now well-known sign "f" or long "s" as short for the "sum of" when considering the sum of an infinity of infinitesimals as is done in the method of indivisibles. Leibnitz himself attributed all his mathematical discoveries to his improvements in notation; and the fact that we still use and appreciate Leibnitz's "f" (and one must add his "d") even though our views as to the principles are very different from those of his school, is perhaps the best testimony to the question of notation. The integral calculus may be distinguished from the differential calculus by another feature than inversion; namely, by the greater importance in it of imaginaries. The integral calculus is frequently called the indirect or inverse method of fluxions, the analytic processes by which a function may be found such that being differentiated it shall produce the given differential. By writers on "fluxions" this function is called the "fluent" or the flowing quantity. By writers on the infinitesimal calculus it is called the integral of the proposed differential. The origin and constitution of quantities is called "fluxions" in the scheme of Sir Isaac Newton (1642–1727), because conceived to express the manner of generation of quantities by the motion of other quantities. In the scheme of Leibnitz the language employed is "infinitesimals" or "differences"; because they are conceived to express the constant addition of one indefinitely small quantity to another. In the scheme of Newton, or "fluxions," the finding of the sum of all differences is called the "inverse" or the "indirect method." It is thus that this method of obtaining the quantity generated is identical with the method of finding the "fluents." And this same method in the language of Leibnitz is called "integration" or the finding of the "integrals." The two systems are therefore in no respect whatever different except in their origin and in their language; their rules, principles, applications and results are for all practical purposes the same. In Newton's system an "f" or f is used to express the "fluent."

To find the integral of a differential is to integrate that differential, and this process by which this integral is found is called integration. With the integral calculus a mathematician endeavors to transform the given expressions into others which are differentials of known functions, and thus deduce formulas which may be applied to all similar forms. The number of such formulas is said to be unlimited. The collection of Meyer Hirsch is a well arranged and though originally published long ago at Berlin is still useful.

Sir Isaac Newton (1642–1727) undoubtedly arrived at the principles and practice of a method equivalent to the infinitesimal calculus generally much earlier than Leibnitz, and, like Roberval, his conceptions were obtained from the dynamics of Galileo. He considered curves to be described by moving points. An "arc" thus became the "fluent" of the velocity of the point with which it is supposed to be described. Newton's notation (it must be admitted) for the "inverse method of fluxions" was far clumsier, even, and far inferior to Leibnitz's "f," the long "s." And it was owing to the long acrimonious dispute between Newton and Leibnitz, mixed up with insinuations anent what is sometimes mistakenly called "patriotism," that for considerably more than a century British mathematicians failed to perceive the great superiority of the "notation" of Leibnitz. In fact it was not until the beginning of the 19th century that there was formed, at Cambridge, a society to introduce and spread the use of Leibnitz's notation among British mathematicians.

"It may be said" (we quote Sophus Lie) "that the conceptions of differential quotient and *integral*, which in their origin certainly go back to Archimedes, were introduced into modern science by the investigations of Kepler, Descartes, Cavalieri, Fermat and Wallace. . . . The capital discovery that differentiation and integration are *inverse* operations belongs to Newton and Leibnitz" (in *Leipziger Berichte* XLVII, 1895, Math.-phys. Classe, p. 53). And indeed in the opinion of one who has contributed much to the advancement of American mathematics as well as of Britain (indeed, of the world!), J. J. Sylvester, "it seems to be expected of every pilgrim up the slopes of the mathematical Parnassus, that he will at some point or other of his journey sit down and invent a definite integral or two toward the increase of the common stock." (See CALCULUS, INFINITESIMAL and consult his 'Notes to the Meditation of Poncelet's Theorem,' Mathematical Papers, Vol II, p. 214). INTEGRAL EQUATIONS. An integral equation is an equation connecting two variables, an independent variable x, and a dependent variable u, in which u occurs (in at least one term) under the sign of integration. An example of such an equation is

$$(1)\quad f(x) = g(x)u(x) + \int_a^b K(x, t)u(t)\,dt,$$

in which $f(x)$ and $g(x)$ are given functions of x, $K(x, t)$ is a given function of x and t, and a, b are known functions of x, one or both of which may be constant. The above equation is called *linear*, since u enters to the first degree only. It is *homogeneous* when $f(x)$ is identically zero. It is the most general form of linear equation. The fundamental problem connected with eq. (1) is to solve it for the unknown u; that is, to express u as a known function of x.

The theory of integral equations is the most recent development of importance in the domain of pure mathematics. The foundation for a general theory of such equations was laid by Volterra in several papers published in Italian scientific journals in 1896. Since then this new field has developed with great rapidity and already has an extensive literature. In spite of this rapid growth the magnitude and difficulties of the problem in its general form are such that only the simplest cases have been worked out with any degree of completeness. These cases group themselves under the following four types:

I. Volterra's equation of the 1st kind:

$$f(x) = \int_0^x K(x, t)u(t)\,dt;$$

II. Volterra's equation of the 2d kind:

$$f(x) = u(x) + \lambda\int_0^x K(x, t)u(t)\,dt;$$

III. Fredholm's equation of the 1st kind:

$$f(x) = \int_0^1 K(x, t)u(t)\,dt;$$

IV. Fredholm's equation of the 2d kind:

$$f(x) = u(x) + \lambda\int_0^1 K(x, t)u(t)\,dt.$$

The function $K(x, t)$ is called the *kernel* of the given equation (It., nucleo; Fr., noyau; Ger., Kern); λ is an arbitrary constant.

These types include the equations that naturally present themselves in connection with other branches of mathematics or in the solution of physical problems. It was, in fact, from such sources that integral equations began to claim the attention of mathematicians and to press for a systematic investigation. The first attempt to solve an integral equation occurs in a memoir by Abel, published in 1823 in connection with the following mechanical problem: To determine the arc of a curve situated in a vertical plane such that a heavy particle starting at rest from the highest point P of the arc and moving by the attraction of gravity along the curve to its lowest point O, shall make the descent in a time $f(h)$ which is required to be a given function of the vertical altitude h between O and P. This problem leads to the integral equation

$$\sqrt{2g}\,f(h) = \int_0^h \frac{u(y)\,dy}{\sqrt{h-y}}$$

in which $2g$ is the acceleration due to gravity, approximately 32, and $u(y)$ is the unknown function $\sqrt{1+\left(\frac{dx}{dy}\right)^2}$, x and y being the rectangular coördinates of a variable point on the required curve. It will be observed that Abel's equation is of Type I, with $K(h, y) = \frac{1}{\sqrt{h-y}}$.

Abel found the solution of this equation to be

$$u(y) = \frac{\sqrt{2g}}{\pi}\frac{d}{dy}\int_0^y \frac{f(h)\,dh}{\sqrt{y-h}}.$$

The simplest case is that in which $f(h)$ is constant. This is the celebrated problem of the tautochrone, which may be stated as follows: To find an arc of a curve such that a heavy particle descending along it under the action of gravity shall arrive at the lowest point in the same time, from whatever point of the curve the point begins to fall. The above solution readily leads, in this case, to an inverted cycloid with its vertex at the lowest point.

Abel was the first to perceive the essential character of integral equations and to make some effort to develop a method for their solution. He applied his ideas to the more general equation

$$f(x)=\int_0^x \frac{u(t)\,dt}{(x-t)^a} \quad , \quad 0<a<1 \quad ,$$

for which he obtained a solution by the aid of infinite series. This method is not regarded, however, as satisfactory and cannot therefore be considered as affording a basis for a general theory. In the interval between Abel's first paper and Volterra's fundamental work, several writers had occasion to solve integral equations in connection with problems of mathematical physics. In particular, Lionville (1832), who was the next after Abel to consider this subject, and who apparently was unaware of the work of his predecessor, was led to Abel's equation in connection with various physical problems. He introduced the method of successive substitutions which has recently been made applicable to much more difficult equations. The first attempt to solve an equation of the Fredholm type was made by Neumann (1877) in his celebrated method for the solution of Dirichlet's problem. This consists in developing $u(x)$ in increasing powers of λ. But Neumann's development, while converging in the case of Dirichlet's problem, does not converge in the general case. Neumann's method was applied with success, however, by Volterra to the general equation of Type II. In a brilliant memoir published by the Swedish mathematician, Fredholm, in 1903, a general method for solving equations of types III and IV was given, thus completing, at least in outline, the theory for linear equations.

While integral equations have found their greatest usefulness in the field of applied mathematics, they are of importance also in connection with other lines of pure mathematics, such as Theory of Functions, Calculus of Variations and Differential Equations. In the first of these, mention has already been made of the fundamental problem of Dirichlet: To determine the values of a harmonic function within a region bounded by a closed curve, given the value of the function at every point of the boundary. It is with differential equations, however, that this subject has the closest contact. In many cases a single integral equation is the equivalent of a differential equation together with certain auxiliary equations of condition. Lionville, in 1837, solved a differential equation by means of an integral equation in order to express the desired solution in the form of a series which should converge with sufficient rapidity. In dealing with equations containing more than one independent variable, the integral equation has this advantage over the corresponding partial differential equation, in that the extension from one variable to several variables offers no appreciable increase in difficulty in the former case, while the difficulty is seriously augmented in the latter case. There has also been developed a theory of integro-differential equations which involve not only the unknown function $u(x)$ but its derivatives as well. These are likewise of importance in physical problems.

For a detailed exposition of the theory of integral equations, the reader is referred to the following admirable works: 'An Introduction to the Study of Integral Equations,' by Bôcher (Cambridge 1909); 'Leçons sur les équations intégrales et les équations intégro-différentielles,' by Volterra (Paris 1913); 'Elementi della teoria delle equazioni integrali lineari,' by Vivanti (Milan 1916).

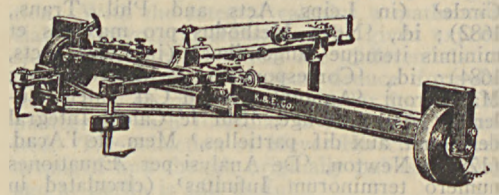
Professor of Mathematics, Cornell University.

INTEGRAPHS. See INTEGRATORS.

INTEGRATORS and INTEGRAPHS, instruments for ascertaining the area and moments relative to any axis of any figure by tracing its outline. They facilitate finding displacement, moments of stability and inertia, centre of gravity, etc., of ships; the tensile strength, resistance and safe load of beams, girders, cables and the contents of embankments, cuts, etc. The



Mechanical Integraph.

integraph plots the integral curves as the operator traces the outline of the figure. The value of the ordinate of this curve can be measured off on paper or read on a finely graduated bar. This value multiplied by the constant of the instrument gives the area of the figure. By tracing the new curve in the manner that the outline of the figure was traced the integral curve of the next higher order is drawn by the instrument, the ordinate of which, multiplied by the constant gives the moment of the original diagram. By repeating the operation the moment of inertia and moments of the 4th, 5th, etc., order can be found. This instrument is of great value in shipbuilding and various kinds of construction.

INTEGUMENT. See SKIN.

INTELLECT, in philosophy and in psychology, the thinking principle of a mental constitution. The word is derived from the Latin *intellectus,* discernment by the senses, from *intellegere* or *intelligere; intellectus — a,— um* is derived from *inter* between and *legere* to gather, or to collect, or to choose; and thus conveys the general idea of "that which has power to choose between." In modern psychology intellect is the designation of the whole cognitive power as distinguished from feeling, sensation, volition and conation. See PSYCHOLOGY.

INTELLECTUALISM, in philosophy, theories which emphasize the intellect as contrasted with the affective and volitional aspects of consciousness. In philosophy it applies, for example, to Herbart's doctrine of presentations, in which cognitive experiences are made primary in the explanation of mind. The historical antithesis between sensation and intellect gives the term intellectualism to theories which find the ultimate nature of reality in some form of thought or reason. By some reality is reduced to intellectual relations. In æsthetics the view of intellectualism regards the ideas suggested by an object as the important factors in beauty. Recent philosophic thought, however, is departing from the crass intellectualism of even a few years ago. Bergson is the greatest figure who has opposed intellectualism in our day.

INTELLIGENCE. See INTELLECT.

INTELLIGENCE IN ANIMALS. See ANIMAL, MIND IN THE BRUTE.

INTENSITY OF SENSATION. Every sensation has at least four attributes: Quality, clearness, duration and intensity. No one of these can be further defined than to say it is an aspect of immediate experience. By intensity of sensation, therefore, is meant that aspect of experience which, for example, we ascribe to tones as loud or faint, to colors as bright or dull, to pressures as heavy or light, to tastes and smells as strong or weak. It is important to distinguish between intensity of a sensation and intensity of stimulus. The latter is physical, and is always measurable by some physical unit; the physical intensity of tones, for example, may be measured by amount of physical energy, weights by number of grams or ounces, lights by so much candle power, etc.

Intensity of sensation is partially conditioned upon intensity of stimulus. There are stimuli, however, which do not give rise to sensation; some tones are too faint to be heard, some weights too light to be felt, some solutions too weak to arouse taste, etc. We have then, as a first problem, to determine the intensity of stimulus which will just produce a sensation. Such a determination, to be valid, must be made under rigorously controlled conditions; the possibilities of error on the part of the observer are so numerous that the same type of methodical procedure is as necessary for its determination as for the just noticeable difference. (See DISCRIMINATION, SENSIBLE). The magnitude representing the stimulus which just arouses a sensation is known as the stimulus-limen, or RL. This may be defined as that stimulus which, in 50 per cent of a large number of observations, is reported as "present," while in the remaining 50 per cent it is reported as "not present." It is a calculated value; and like the DL, it is an ideal, a most probable value.

We may, nevertheless, think of the RL as a point somewhere on the scale of stimulus-intensity. The lower limit of this scale is zero intensity and it is, therefore, below the RL; the upper limit is infinity, since theoretically we may gradually increase the energy of a tonal vibration, add candle power to candle power, pile gram upon gram without end. The intensity of sensation which corresponds to the RL is, on the other hand, the zero point of the scale of sensation-intensities; theoretically, the upper limit of this scale is again infinity; but practically it is subject to the capacity of the sense-organ.

We have seen that the unit of the stimulus scale is some physical unit like the gram or candle-power. What now is the unit of the sensation scale? The answer to this question is fundamental to the larger problem of mental measurement. Until the middle of the last century philosophers had said that mental measurement was impossible because there was no unit of measurement in terms of sensation itself. Nevertheless, the astronomers had already divided the stars into six magnitudes, and it has since been found that the difference in intensity between a star of the first and one of the second magnitude is approximately equal to that between stars of the second and third, third and fourth, fourth and fifth and fifth and sixth. Each magnitude is, then, a point on a scale, the points are equi-distant as measured by differences in intensity, and the difference between any two continguous points may be taken as the unit of the scale. We may say, therefore, that the difference between stars of the first and sixth magnitude is five times the difference between the first and second magnitudes. Such a unit, which we may call a supra-liminal difference, is, of course, an arbitrary one, but it has proved to be adequate to the measurement of intensity in nearly if not all sense departments. A unit which gives less direct measurements but which has a greater range of applicability, because its magnitude is expressed in terms of the stimulus, is the just noticeable difference or the DL. We cannot assume off hand, to be sure, that all least differences are equal, that least steps at various parts of the scale are equal steps, but the experimental evidence is, on the whole, favorable to this assumption.

What now, it may be asked, is the relation between the two scales, the one of stimulus differences, the other of intensity differences? Do equal differences in intensity of sensation correspond with equal differences of intensity of stimulus? In seeking the answer to this problem we may employ either of our two units of sensation. We have only to determine the physical intensity of every point on the supra-liminal scale, and then see whether the physical differences are or are not equal to the sensation differences; or, employing the other unit, to take a number of DL's from some portion of the scale and then compare the differences between their magnitudes. Since these magnitudes are expressed in terms of the stimulus, the relation of their differences will furnish an immediate answer to our question.

We find, whichever unit we employ, that the two scales do not correspond point for point, that equal differences in intensity of sensation correspond rather with *relatively* equal differences in the intensity of stimulus. Let us suppose, for example, that the points on the sensation scale form an arithmetical series like 1, 2, 3, 4, etc., then the points on the stimulus scale to which these will correspond will form a geometrical series like 2, 4, 8, 16, etc., or like 3, 9, 27, 81, etc.; the exponent of the geometrical series varies with the sense department — for noise it is 4/3, for light 101/100. This law, which is known as Weber's Law (q.v.), explains many phenomena of everyday life which, however, are so common that they often fail to excite our notice. The relation of black print to the white page seems always the same, yet

the intensity of sunlight changes with every hour of the day; the painter is able to simulate a natural scene, yet he cannot begin to reproduce the actual intensities of light and shadow by means of his pigments; the same musical composition may be rendered by orchestra and again by piano without loss of dynamic effect, yet the intensity of the former is much greater than that of the piano. All these result from the fact that the sense impressions depend not upon their absolute but upon their relative likeness. HARRY P. WELD,
Assistant Professor of Psychology, Cornell University.

INTENT, Common, a law term: in the rules of legal construction, the natural sense given to words. It is the rule that when words are used which will bear a natural sense and an artificial one, or one to be made out by argument or inference, the natural sense shall prevail. It is simply the rule of construction and not of addition. Common intent cannot add to a sentence words which have been omitted. (2 H. Blackst. 530). In pleading, certainty is required; but certainty to a common intent is sufficient; that is to say, what upon reasonable construction may be called certain, without recurring to possible facts. (Co. Litt. 203-a, Dougl. 163).

INTENT, INTENTION or **INTENDMENT,** in criminal law and in the law of evidence: the purpose; formulated design; a resolve to do or forbear a particular act; aim; determination; end; object,—which a person may have. It is not synonymous with motive, attempt, or, as some think, with promise. In its literal sense, the stretching of the mind or will toward a particular object.

To render an act criminal or wrongful, intent must exist. And with this intent must be combined a wrongful act, mere intent is not punishable. And generally, perhaps always, intent and act must concur in point of time. But wrongful intent may render criminal an act otherwise lawful.

Intent is in a certain sense essential to the commission of a crime, and in some classes of cases it is necessary to show moral turpitude, but there is a class of cases where purposely doing a thing prohibited by statute may amount to an offense though the act does not involve moral wrong. When shippers pay a rate when under honest belief that it is the lawful rate when it is not, we have an instance of this.

Some jurists incline to a somewhat James-like (see INTENT in psychology) interpretation of Intent, even in law. Intent "is the exercise of intelligent will, the mind being fully aware of the nature and consequences of the act which is about to be done, and with such knowledge, and with full liberty of action, willing and electing to do it." Among such interpretations see Burrills (Circ. Ev. 284, and notes). To accept this method, however, appears to mean the acceptance of "Intent" in what at the beginning of this article is called the "literal sense" rather than the "legal."

A wrong done to the person or property of another is punishable at law without consideration of the intentions of the person committing the violence or trespass. But when an engagement has been made by person, or a written disposition of property executed, the intention of the person making the engagement or signing the deed is fair matter for legal inquiry. In this connection a subsequent stipulation by word of mouth is not competent to nullify or modify the terms of a written engagement. Intent also forms an important part in suits for defamation, fraud and negligence. Negligence must have intent to make it criminal, so must defamation and fraud and malicious mischief. Consult Thayer, 'Preliminary Treatise on Evidence' (1898); Black, 'Construction and Interpretation of Laws' (1896); Hardcastle, 'Rules which govern the Construction and Effect of Statutory Law' (1900).

INTENT, or **INTENT OF CONSCIOUSNESS,** in psychology is virtually identical with the goal of conscious endeavor at a specific moment in time. In German the word *meinen* is probably the nearest equivalent to our word Intent, though either *Sagenwollen,* or the phrase *in Sinne haben* might answer the purpose equally as well. French psychology employs "intention"; Italian, "intento." Modern English "Intent" may also be compared with M.E. the Fr. and O.F. "entent," attention, purpose. All these words, except those of German psychology mentioned above, are in ultimate origin from the Latin word "intentum," or "intensum," the past participle of the Latin verb "intendere," meaning "to intend," "to extend," "to stretch out."

The psychologist James employs "intent" in a manner peculiar to his system of psychology, to designate what intelligent consciousness "means or intends." As stated it is not usually employed in this sense by psychologists. Its usual sense is implied in the definition given at the beginning of this article, and this is a sense which marks a certain point of view from which one may regard an "object." It is almost a law, that in any conscious process having unity of interest there must also exist a corresponding unity of object. This is shown by Baldwin. Exceptions are rather apparent than real. Partial presentations, of course, come before consciousness as appearances, but as appearances, always of one and the same total object, which consciousness is endeavoring to know in its completeness. If our interest be merely attainment of knowledge, fuller, more definite, or more vivid, the object, as it becomes more perfectly known, is identical with the object as previously less perfectly known. For it is, says Baldwin, what the mind consciously means or intends. While one's attention is constantly employed upon an object, the end pursued becomes progressively defined in the process of its achievement. And in so far as such an object remains indefinite, or partially developed in consciousness, it is an intent. The result of a concrete mental determination, that state in which any specific process in consciousness issues and completes itself, is known as "End-state" (the German *Enzu-stand,* the French *etat final,* and the Italian *stato finale*).

Bradley employs "content" in a sense analogous to that in which intent is understood under the definition of it given at the head of this article. Content in this sense, however, is peculiar to Bradley. For as ordinarily applied, content (of consciousness) means all special modifications of conscious experience, whatever may be their nature, and not merely objects of consciousness. Pleasure or pain are thus part of the content of consciousness, but neither are always an object or an intent of consciousness.

Intent is the consciousness, obiterdicta, of the general nature of the end-state, and is mental progress toward an ideal we have successive stages of intent.

INTERCALARY ("called or proclaimed between"), the day added to February in leap-year, also the month or days occasionally inserted in the calendar to make it correspond with the solar year. In botany, the term is applied to the growth of the cell-wall when a new deposition takes place in such a manner that an interposed piece of cell-wall from time to time appears. See CALENDAR.

INTERCESSION, Doctrine of, a theological tenet founded on the Scriptural representation of Christ, who having made the redemption an accomplished fact on earth ascended to plead with his heavenly Father for the sinners redeemed by the shedding of His blood. We are not to suppose that God needs to be interceded with in the sense that he is reluctant to pardon sinners, or that he becomes more disposed to do so through the pleading of Christ. Since it is evident from the whole tenor of the New Testament, as well as from a multitude of special passages, that the sacrifice of Christ on Calvary for the reconciling of sinners unto God was itself the offering of God's own love to the world (John iii, 16–17), we must regard the intercessory work of Christ rather as illustrating the eternal holiness of God and the changeless love of the Saviour, and as intended to keep continually in view the sacrifice of atoning grace whose tender mercy it develops. This doctrine is common alike to Catholics and Protestants. Catholics, however, believe that the Blessed Virgin and the saints intercede indirectly through the Saviour, who alone has the ear of the King of the universe. Mohammed is regarded as a powerful intercessor by his followers.

INTERCHANGEABLE PARTS, of industrial or military implements, are the key to all the vast expansion of modern manufacturing. Without these, only a small fraction of it, and consequently of new population human or animal, agriculture, engineering and industrial civilization in general, could have come into being. A glance at its implications will show that this seemingly extravagant proposition is sober fact.

The principle of interchangeability affects production in two ways: through the original manufacturing, and through repairing. In manufacture it makes possible the turning out, in separate departments, in vast masses at full speed, in exact shape for immediate assembling, of all the individual parts used in great numbers in complicated machines, from the screws of a watch to the rivets of a giant steamship. Without this, the different parts would require an army of fitters to make them work with each other, and indefinitely more time for assembling, hence a much diminished production and higher expense. In repair, if every replaced part of a watch or sewing-machine, a gun or a reaper, had to be individually filed or hammered or reforged into adjustment, the delay and expense would greatly decrease the articles' use and the work done by their means; and for military service, repair would involve so much remanufacturing on the field as to make modern warfare quite impracticable. Now, reflecting that the multiplication of men is conditioned by that of goods and employment, of food by farms and transportation, of the latter by engineering, and so on, the conclusion above is easily substantiated.

Owing to mechanical niceties to be explained later, the principle did not attain much close accuracy in use till toward the middle of the last century; and as might be expected, was first developed in making firearms, where masses of lives were involved and the highest of stakes to be won. The Springfield, Mass., armory was the first to bring it to a high grade of embodiment. Somewhat later, the Waltham Watch Company applied it, under much more difficult conditions, to the minute, sometimes almost microscopic, parts of its watches. The constant effort of all large implement manufacturing for many years has been toward perfecting its application; and its success largely gauges the increased use of machinery in place of men, and of mechanical utilities.

The first requisite is obviously that each part shall come within very small limits of variation, neither stick nor "shuck"; the one stopping or slacking movement and increasing frictional wear and heat, the other making movement ineffective and irregular and breakages likely. Or if, say, a fuse, its cavity must hold pretty closely the same amount of explosive to determine time and goal. Hence the standards of accuracy and craftsmanship must be kept very high; in the long run it is most economical if worth attempting at all. Any saving on expense by slighting severe requirements is more than sunk on increased cost in assembling, to say nothing of rejected work and impaired reputation.

While every step must help to ensure this uniformity, it must be frankly accepted that there is a certainty of some error in each; and the proper course is not to attempt eliminating it wholly—an impossible task, and beyond a certain limit costing more than it is worth,—but to determine the limits up to which it is neglectible, and hold it within them. Constant accurate measurement for those limits is therefore the basic need; and the limits themselves depend on the class of work and closeness of adjustment required. Thus, if a piece is to be one inch in a given dimension, with an ordinary steel scale we are sure of it within about 1/100 inch; with a micrometer, about 1/4000; on a measuring machine, about 1/100,000. The latter is not available in most small establishments; and when the standard of accuracy must be held high, the best means of

guarding against discrepancies from independent measurements is by the establishment of a model. All measurements are then comparative instead of direct, and correct within much smaller limits of error. If this be neglected, its lack will be a constant hindrance to the high standard requisite in all the better classes of implements; and no other system so economical and reliable has yet been devised within the general reach. An example is the 36-inch bronze bar in government archives as a legal standard of length. Drawings of each part for general shop reference should also be provided, with all dimensions and tolerances clearly shown.

Next must be established the allowable deviations from the model. These are controlled mainly by two factors: first, the proper functioning of the whole,—thus the largest shaft must always assemble into the smallest bearing; second, how small a variation can be maintained in manufacture. This done, means of testing the accordance of the parts with these standards must be furnished; namely, gauges representing the largest and smallest permissible size for each important dimension. An inspection organization should be carefully trained to use these, and throw out any piece not conforming to them, to save further labor on it or mischief in assembling, and prevent more of its sort being made. Such a service can retrench much useless expense; in fact, if in any large plant it does not save far more than its cost in a year, something is very wrong.

But further uniformities than size, which gauges and drawings concern solely, are called for. Physical characteristics must conform also. This is effected by specifications dealing itemwise with strength, hardness and finish, composition of materials, and vital points to be watched most closely in course of making; and prescribing both frequency of tests (enough to establish sure accuracy) and manner of manufacture, also in detail any special treatment contingently called for, as heat treatment of steel.

Equipment to obtain results simply and inexpensively is a business necessity. It must be carefully suited to the special requirements of the product, as a type of appliance very satisfactory in one class of manufacturing may be quite unfit for another.

These steps are indispensable for interchangeability. The model should remain fixed till a new or improved design is devised. The tolerances are subject to some experimental change, but should be put on a fixed basis at the earliest feasible moment; and never altered to suit inaccuracies in manufacturing methods or other temporary convenience, as the ultimate loss outweighs the saving. The specifications of course change with new methods or materials. All these are so essentially interwoven that slighting any one makes the rest unsure, and every change should be carefully considered as to affecting the whole system. A well-balanced whole will give far more efficient results than one with some elements much in advance of the others.

The Model.—This affords for all dimensions a direct comparison against a physical standard, the most uniform method available with the usual measuring equipment. The whole object will be to reproduce it in quantity as closely as possible, and such reproduction should be carefully kept in mind in developing it. To aid in this, no operations on it should be performed by hand tools (as a file), because such cuts are hardest and costliest to reproduce. All cuts should be machining cuts.

But its development consists of far more than merely producing a piece of work as a standard for other production. Every cut taken should be governed, where possible, by some profile plate, size block, angle plate, form tool or master plate that will be available later for construction of the manufacturing equipment. This will eliminate much of the necessity for several independent settings to reproduce the same sizes or shapes, ensure much greater uniformity throughout, and in the long run prove a real economy. Every step must be considered as to how it affects not only the model itself, but the reproduction of these same sizes, profiles and locations in the working tools and equipment.

To make the model, as often done, an independent unit merely for comparison of measurements, is a wasteful economy far overbalanced by increased expense of making the necessary tools. The more intricate the model, the greater the economy in liberal use of master plates, templets and all other useful special equipment. It should be very carefully kept, not handled or hit, and used only in cases of question and for verifying tools and gauges as needed. It must not be confused with the experimental models; the work is assumed to be past the experimental stage. This ultimate standard is in a class by itself, and must be done by skilled craftsmen of the highest type. At present the manufacturers of firearms are the leaders in this branch.

The Tolerances, or Allowed Variations.—Several factors are involved in establishing these. First, they must never be so great as to injure the operation of the mechanism; yet since expense of manufacturing increases very fast with severity of requirements, economy demands as large a tolerance as consistent with proper functioning. Second, those on one piece must not overlap the sizes fixed for companion parts. The extreme sizes must be compared with each other; so that, for example, the largest pin will always enter the smallest hole, the smallest never be too loose in the largest hole. Third, it must always be kept in mind that the only dimension on any part controllable within close limits is the distance between where it is supported and the surface being machined by the cutting tool. Thus the method of holding the work determines the correct locations of the dimensions; or, vice-versa, those locations determine the holding points for machining. Fourth, the accuracy of the machining facilities available determine the actual possibilities of closeness, and hence should be carefully considered in the original design. The actual extent of tolerances will be a matter of experiment or experience. The same care should be exercised, and the same factors considered, in altering a tolerance as in establishing it.

The Drawings.—These have been used since very early times, and in many cases today are the only standards; models not being in universal use. Even with models, they are always an invaluable aid for shop reference; while since the invention of cheap duplicating processes such as blue-prints, photostats, etc., their frequent use is actively encouraged. They mostly show each part in detail, give all required dimensions and usually the tolerances. Great care must be exercised in placing the dimensions on them. These should be shown between the points intended to hold certain relations to each other. In no case should the location of any point be given with limits from more than one point in the same straight line; otherwise the tolerances will be misleading, as it is impossible to control the variation between more than two such points at once. Wherever possible, a working point or surface should be established in each plane, and all points located from this only; much expense and confusion will be eliminated. Whenever the drawing itself does not give sufficient information, notes should be added.

The Gauges are measuring instruments of fixed dimensions; and where tolerances are established, show two sizes, maximum and minimum, differing by the smallest amount attainable in practice. For example, the gauge for the size of a hole would consist of two cylinders, the smaller just entering the hole and the larger not. The wear on gauges is considerable, and they should be frequently and carefully inspected; preferably by comparison of measurements with a duplicate set of master gauges, themselves carefully checked against the model, and standards of the allowable variations from it. Their design depends upon their purpose. Wherever possible, they should admit of ready repair or correction. It is often possible so to construct them that the parts which control the gauging sizes will receive no wear, thus keeping the maintenance cost very low and insuring the duplication of the original sizes.

Owing to the inevitable factor of error above noted, it is impossible to make any two gauges exactly alike; and to make them within 1/100,000 inch of each other would cost a hundred times as much as within 1/10,000. With this variation, however slight, and with work going through several successive inspections, much difficulty will be met unless proper precautions are taken. No matter how closely several sets of gauges are made to each other, after very short use a variation develops, due to difference in amount of wear and in methods of handling them. When working to gauges, the work will always follow the gauges. The setting of a tool is not changed, a tap or a reamer is not replaced, as long as the work passes the gauges used. So if they wear excessively and are not set right, the work gets farther and farther away from its original standard, and discovery is perhaps made by loss and discredit. The following practice, if strictly adhered to, will almost eliminate these difficulties, and reduce the entire problem to whether the combination of operator, machine and tools is suitable to produce duplicate work:

First, a set of master gauges, duplicates to the working gauges, and checked closely to whatever standard is used. These must under no circumstances be employed to gauge a piece of work; only as standards to check the working gauges.

Second, a positive limit of error for gauges, governed by the tolerance on the given part and the cost of the gauge; all to be inside the total tolerance allowed on the part. For example, a maximum plug gauge could be smaller but never larger than the master, a minimum larger but never smaller.

Third, the sets of gauges should be sorted into groups, according to requirements of inspection. Assuming a shop inspection and a final inspection, three groups would be needed; one for the operators, one for shop inspectors, one for final inspectors. Again assuming that the final inspectors will use two sets constantly, the shop inspectors three, and the operators four, nine sets will be in use at the same time. All gauges should be graded according to size; the two of each type closest to the masters will be sent to the final inspectors; the next three, varying a little more inside the limits, to the shop inspectors; the last four, with the greatest but still allowable variation, to the operators. Each operator should hold his work to the gauges furnished him, regardless of any variance from those of other operators.

Fourth, all gauges in use should be checked periodically against the masters, and discarded, repaired, or regraded according to condition, regardless of which job they were returned from. The frequency of this will be determined by practice, as a capable gauge man will soon determine how many pieces a gauge will measure in given hands without losing its size. Some can be used only on a few hundred pieces before wearing appreciably, others will measure several thousand. Work manufactured continuously needs a duplicate outfit. All gauges of any one type, or the duplicates of any one master, to be used during the same period, should be checked at the same time, to permit of proper grading and comparison.

Fifth, all persons who use the gauges should be carefully instructed and trained in their use. A gauge is an expensive and comparatively delicate instrument, and a careless operator can spoil one on the first piece he gauges; or a foreman with one in his drawer can ruin it by knocking around or mishandling. The final inspectors should set the standard of handling and use, and instruct all others as far as possible to use them likewise.

Work must be held to slightly closer tolerances than the maximum allowable, since it is impossible to work to a maximum without sometimes exceeding it; so the operator has the gauges allowing the smallest working tolerances, as his normally receive the greatest amount of wear.

The Specifications.—Only on very simple or familiar mechanisms do the drawings, gauges, etc., give sufficient information for intelligent manufacture. Specifications should form an integral part of the equipment. As said above, they should explain clearly and definitely the requirements and desired results, character and composition of materials, the chief functioning points and sizes, class of workmanship demanded, and any unusual manufacturing methods required; with the character and method of inspection. In fact, any information of value in the process should find here a permanent record. If any requirements are unimportant, and economy is the main factor, that fact should be stated also. These specifications may be incorporated on the

drawings, if desirable and they are simple; otherwise be kept as an independent record, and revised to keep abreast of current practice. They are as yet a rarity in general establishments, but their value and help are becoming more widely acknowledged. The best examples are in government supplies, as munitions.

The Manufacturing Equipment consists of the tools, jigs, fixtures and machines required. A jig or fixture is a device for holding a piece in proper position while some machining operation is performed upon it. Each operation usually needs a special jig. Its general type or design depends entirely upon the part to be wrought. One factor, however, remains constant, and must always be kept in mind for satisfactory results; the locating points for any operation should always be those from which the machined surface is dimensioned. A strict observance of this fundamental principle will eliminate many manufacturing difficulties.

If a model has been suitably developed, many size blocks, master plates and other valuable accessories will be available, that will not only ensure greater accuracy in the equipment and a corresponding uniformity in the product, but greatly decreased expense in equipment costs. In any event, if a model is available, all equipment should be carefully tested to it before being forwarded to the production departments.

The Production, a general mechanical business, need not be dealt with here; the next step is

The Inspection.— This department has the responsibility, and should have the power, of maintaining the standards of accuracy and quality. It should be entirely independent of the production department, whose duties are incompatible with its own, and too often held and performed as hostile. It must be provided with all needful testing and checking apparatus; and its duty is to see that all work is up to the mark before passing from machine to machine, or department to department. Its detailed duties depend upon the nature of the product; but in any case its personnel should be individuals of good judgment, intimately acquainted with the requirements, and well trained in the use of the testing facilities.

The Assembling furnishes final proof whether due attention has been paid to the factors of size; unhappily, the test for quality of material mostly lies in use, and detection of neglect comes too late. If the parts may be assembled without fitting or further machining, and the mechanism performs its functions properly, it is conclusive evidence that the dimensions have been kept true. On the other hand, if fitting or other modifications are necessary, it is equally conclusive proof that some vital factor has been overlooked, and investigation to locate and correct the trouble should follow. In truly interchangeable work, no machining will be performed in the assembling room.

Interchangeable manufacturing requires many types of skilled workmen. As operations are simplified, the needed skill becomes less; but a corresponding increase is required in preparation work and supervision. The basic principles remain fixed, but their application must be modified to suit particular factors of product, class of equipment available and type of workmen employed.

EARLE BUCKINGHAM,
Associate Member, American Society Mechanical Engineers.

INTERCOASTAL, or INTRACOASTAL, CANAL, The, of Louisiana and Texas, a government project in process of construction for the purpose of providing an inland waterway around the coast of those States, and connecting the Mississippi River with the Rio Grande. An act of Congress of 3 March 1873 ordered a survey with a view to connecting the Mississippi River with the Rio Grande by cuts and canals, joining the lakes, bays, bayous and lagunas along the margin of the Gulf of Mexico. No action was taken on the report by Congress at that time. The project was revived by Texas and Louisiana interests and a new survey was authorized by the act of 3 March 1905 and the examination from the Mississippi River at Donaldsonville, La., to the Rio Grande was made by Maj. Edgar Jadwin, of the United States Engineers. Subsequently the Donaldsonville exit was changed to Plaquemine by reason of the locks at that place. The Mississippi-Rio Grande waterway is divided by the United States Engineers into sections as follows — each section being considered as a distinct project: Mississippi River to Bayou Teche, Bayou Teche to Mermentau River, Mermentau River to Sabine River, Port Arthur, Tex., to Galveston Bay, Galveston to Brazos River, Brazos River to Pass Cavallo, Pass Cavallo to Aransas Pass, Aransas Pass to Brazos Santiago, Brazos Santiago to the Rio Grande. The section between the Mississippi River and the Sabine River embraces practically all of southern Louisiana and lies well within the region of alluvial deposit made by the Mississippi River. It consists of wide areas of marsh, numerous cypress swamps and many lakes which are from one-half to 30 miles in length. Many bayous, having a general north and south direction, intersect and these bayous are all deep, most of them having 20 to 30 feet for miles in succession. There are no elevations, thus making it possible to construct a tide-level canal across the entire section. Although the bayous are deep, the bays and lakes are usually shallow, ranging from 6 to 12 feet in depth. From the Sabine River to the Rio Grande the route follows mainly the lagunas, or bays, lying behind the islands which parallel the Texas mainland. The canal passes through the cypress, salt, sugar, rice, oil and pine sections of Louisiana and serves the great sulphur mines of Louisiana as well as those of Texas at Freeport. These two mines, the Louisiana deposit being found at Sulphur in Calcasieu Parish, furnish practically the entire supply of sulphur to the United States. The status of the canal is as follows: Mississippi River to Mermentau River completed with a ruling depth of five feet, reached either through the locks on the Mississippi River at Plaquemine, La., to the Atchafalaya River, or through one of the privately owned canals opposite New Orleans. Mermentau River to Sabine River, work in progress; depth, Mermentau-Calcasieu stretch, seven feet; Calcasieu-Sabine, 12 feet. Sabine River to Port Arthur and Port Sabine, 25 feet. Sabine to Galveston, approved on a depth of nine feet. Galveston to Corpus Christi, completed on five foot depth. Corpus Christi to Brazos Santiago, not yet undertaken. Brazos Santiago to the Rio Grande at Brownsville, Tex., work in progress. The five foot depth has a bottom width of 40 feet; the seven foot depth a bottom width of 75 feet and the 9 and 12 foot depths have a bottom width of 100 feet.

With the completion of the canal all the markets of the Mississippi and its navigable tributaries can be reached safely and cheaply, and the communication afforded opens to the Mississippi River more than 1,000 miles of the navigable rivers of Louisiana and Texas. The commercial need of the waterway has been well established; its military value is obvious.

In the marsh areas of southern Louisiana are many so-called islands which are fertile strips of higher land in the marsh; these are served by the waterway and railroad construction is impractical. The best proof of the need and practicability of the canal is found in the fact that many private canals exist and are extensively used, serving a triple purpose — transportation, irrigation and reclamation. The last feature has been greatly stimulated by the intercoastal canal, and in southern Louisiana there are more than 50 extensive reclamation districts embracing a total area of over 300,000 acres. The appropriations made by the United States thus far are in excess of $2,000,000. It is estimated that $10,000,000 more will be required to complete the work. In some sections of Louisiana the local community has contributed to the cost and in all sections the rights-of-way, 300 feet in width, are furnished without cost to the United States.

INTERCOLONIAL CONTROVERSIES. See BOUNDARIES OF THE UNITED STATES.

INTERCOLONIAL RAILWAY. This railway and the Prince Edward Island Railway are owned and operated by the government of Canada as part of the government railways. They are under the charge of the Department of Railways and Canals, which is presided over by the Minister of Railways and Canals, who is a cabinet minister. The intercolonial extends through the provinces of Quebec, New Brunswick and Nova Scotia, connecting the cities of Montreal and Quebec with the cities of Saint John, Halifax and Sidney on the Atlantic Coast. Its length, including branches, is 1,562 miles.

The history of the Intercolonial is interesting, but there is space here for only a brief out line. The construction of a railway from the Atlantic Ocean to the Saint Lawrence River at Quebec, through the British provinces, was proposed in 1832. An exploratory survey from Point Levis, opposite Quebec, to Saint Andrews on the Bay of Fundy, was made, with the assistance of the British government, in 1836, and a practicable route was found, but nothing further was done at that time because of representations from the United States government that part of the surveys were in territory claimed by the State of Maine. Other explorations were subsequently made until 1846, when the Royal Engineers, under instructions from the British government, commenced the survey of several routes from Halifax to Quebec. These surveys were completed in 1848, and the route recommended by the engineers was, generally speaking, that adopted when the Intercolonial was constructed many years afterward. The surveys showed that there were several routes by which such a railway could be constructed, but the provinces considered that the work was too great and costly for their unaided resources; under these circumstances the greater project was laid aside for a time and each of the provinces in its own way, and independently of the others, turned its attention to the construction of railways which were destined afterward to form parts of the Intercolonial.

The province of Canada in 1849 passed an act affording assistance to railway companies by guaranteeing their bonds, and the Halifax and Quebec Railway was particularly mentioned in this act. In 1852 the Grand Trunk Railway Company was incorporated and subsidized. Another company was also incorporated and subsidized, in the same year, to build a railway from opposite Quebec to Trois Pistoles. This company was amalgamated with the Grand Trunk Railway Company, and the latter built the line from Point Levis, opposite Quebec, to Rivière du Loup, 126 miles, which was opened in 1860. The company did not build as far eastward as Trois Pistoles.

The province of New Brunswick in 1853 also commenced railway construction, and built, as a government work, a line from Saint John to Point du Chene on the Gulf of Saint Lawrence, 108 miles. It was opened in 1860, and was called the European and North American Railway. In 1865 the province entered into a contract for an extension of this railway eastward to the boundary of Nova Scotia, and this was completed and opened in December 1870.

The province of Nova Scotia commenced in June 1854 the construction of a government railway, and in December 1858 it was opened from Halifax to Truro, 61 miles, with a branch to Windsor, 32 miles. It was called the Nova Scotia Railway. The province afterward extended this railway from Truro to Pictou on the Gulf of Saint Lawrence, 52 miles, this extension being opened in May 1867.

The people still desired complete railway communication between the provinces, and in 1864 and 1865 a survey was made of a route to connect Truro, Nova Scotia, with Rivière du Loup, Quebec, the link which remained to be constructed.

On 1 July 1867 the provinces of Canada, Nova Scotia and New Brunswick were, by an act of the Parliament of Great Britain, united in a confederation called the Dominion of Canada. By that act the railways already mentioned, owned by the provinces of Nova Scotia and New Brunswick, became the property of the Dominion. That act also provided that an intercolonial railway connecting the river Saint Lawrence with the city of Halifax should be immediately constructed by the government of Canada; and by another act of the same Parliament, in the same year, the British government was authorized to guarantee the interest on a loan, not exceeding £3,000,000 sterling, to be raised by Canada, for the purpose of constructing the railway between Rivière du Loup and

Truro. These arrangements were carried out, the work of construction of the Intercolonial was commenced without delay and prosecuted without intermission, and on 9 Nov. 1872 the division extending from Truro to Amherst, 76 miles, was opened. This division formed the connection between the Nova Scotia Railway and the European and North American Railway, and completed railway communication between Halifax and Saint John. The three railways, a total of 370 miles, were on the above date consolidated under the name of the Intercolonial Railway. These three railways forming the Intercolonial had been built with a gauge of 5 feet 6 inches, and they remained that gauge until 18 June 1875, when they were changed to 4 feet 8½ inches, the gauge in general use on this continent, and which had been adopted for the Intercolonial. Other extensions have been made from time to time, the following being the lines taken over within recent years: In 1911, the line from Ferrona Junction to Sunny Brae (Nova Scotia) was purchased (13 miles); in 1914, the New Brunswick and Prince Edward Island Railway (36 miles) began to be operated in connection with the Intercolonial; and in 1915, the Saint John and Quebec Railway, from Gagetown to Centerville, New Brunswick (105 miles). The Intercolonial Railway of New Brunswick, from Campbellton to Saint Leonards, New Brunswick, and the Maine border, has been operated since 1914 by the Intercolonial with the option of purchase within a five-year period. Receipts for year to 30 June 1915: Passengers, $3,947,-891; freight $7,187,449; gross receipts, $11,259,-710; operating expenses, $11,348,756. At 30 June 1915 the system had 411 locomotives, 500 passenger cars and 13,407 freight cars. The total cost of lines was $109,221,080.

The Intercolonial Railway was built, not as a commercial but as a political undertaking, and it has never paid, and was never expected to pay, interest on the capital investment. It has the disadvantage of having a circuitous route nearly 250 miles longer than that of the Canadian Pacific between Montreal and Saint John.

INTERCOLUMNIATION (from Lat. *inter*, between, *columna*, column), in classical architecture, refers to the clear space between two columns of a peristylos, or system of roof-supporting columns, though sometimes it means the distance measured at the lower parts of shafts, between their centres, and referred to in terms of diameter of a column at its base. A Roman architect and engineer, Vitruvius, a contemporary of Augustus, enumerates five varieties of intercolumniation, assigning by means of the foregoing scale of measurement, definite proportions to each. They are as follows:

1. Pycnostylos (Gr. *πυκνος*, "thick," and *στυλες*, column, implying thick arrangement), in which the spacing equals one diameter and a half. 2. Systylos (Gr. *συν*, with, and *στυλος*, column, that is, with columns harmoniously arranged), where columns are two diameters apart. 3. Eustylos (Gr. *ευ*, well, and *στυλος* column, as the derivation implies, a style preferred, and meaning with columns a due distance apart). Some authorities say the proportion was two diameters and a quarter; others, two diameters and a half. 4. Diastylos (Gr. *δια*, through, and *στυλος* column, implying columns wide apart), in which the space between the columns consisted of three, or even, according to some authorities, of four diameters. 5. Araeostylos (Gr. *άραιος*, wide, and *στυλος*, column, implying columns sparsely ranged), that style in which the distance between the columns used is four and sometimes five diameters,—the former distance being however that to which the name is in strict usage applied. It is suited only to the Tuscan order, and the span is possible only when the epistylium or architrave is of wood. A sixth arrangement is also known, the Araeosystylos (Gr. *αραιος*, wide, *συν*, with, *στυλος*, column), in which the intercolumniations are alternately systylos and araeostylos. This way of building places four columns in a space equal to eight diameters and a half. The central intercolumniation is equal to three diameters and a half, and the others on each side only half a diameter, so that coupled columns are introduced.

In the ruined remains of fine architecture which have survived down to the present time, ancient intercolumniation rarely if ever illustrates the Vitruvian dimensions, which therefore have, by some authorities, been regarded as arbitrary. He appears to have spoken only of Roman forms, or only of those of the Greek style, with which he became acquainted through such reports about Hellenic temples, as he had among his authorities. In the Doric examples, such as the Parthenon and the temple of Diana Propylæa at Eleusis, the proportion is said to be one and one-quarter (1¼) diameters. Temples of the Ionic and Corinthian order resemble each other. The proportions in these are, on the whole, greater; they average about two diameters. But it would be a mistake to overlook in this connection the relative proportion of height to diameter in a column, and to disregard the width of the peristyle. In one temple of the Ionic order, that of Apollo Smintheus, in Asia Minor, the peristyle is of double width, and the intercolumniation is just one and one-half diameters. To the ancients, the eustylos was the most correct as well as the most beautiful arrangement; and the author of 'De Architectura' preferred this proportion to that of any of the others, declaring it at one and the same time the strongest and the most convenient. Consult Vitruvius, 'De Architectura" (trans. by Morgan, Prof. Morris H., as 'Vitruvius: the Ten Books on Architecture' (Cambridge, Mass., 1915).

INTERDICT, an ecclesiastical decree which forbids the performance of certain acts of public worship. When an interdict was laid upon a town, district or country, all the churches were closed, the bells were silent, the sacraments, except infant baptism and extreme unction (and sometimes even these), were withheld, the rites of burial were not performed and all the public ceremonies of religion were suspended. Interdicts may be general, as applied to a country or city; particular, as applied to a parish or diocese; personal, as applied to a person, or some class of persons. The bishops seem to have anciently exercised the right of publishing interdicts; for in 870 Hincmar, bishop of Laon in France, issued one against a parish in his diocese. One of the earliest censures of this sort on record was imposed upon the city of Rouen in the 6th century on account of the murder of the Archbishop Pretextatus by order of Queen Fredegonda. In 997 Gregory V laid the kingdom of France under an interdict because King Robert had married his cousin, and the king was abandoned by most of his court. The same penalty was inflicted upon the kingdom of England under Stephen (1147) by Eugenius III, under John (1207) by Innocent III, under Henry VIII (1535) with little effect by Paul III and under Elizabeth (1587) by Sixtus V. Adrian IV laid Rome under an interdict for the purpose of compelling the Romans to drive out Arnold of Brescia. Gregory IX made use of the same instrument of compulsion in his quarrel with the Emperor Frederic II. During the Middle Ages the interdict was a powerful engine of attack for the popes in their contests with sovereigns, as the popular dread of its effects was so great that kings were often forced by rebellions to submit to almost any conditions in order that it might be taken off. From the time of the Reformation general and local interdicts have become rare. When Paul V laid Venice under an interdict in 1606, the churches were not closed, and only a minority of the bishops submitted to it.

INTERDICT, in Scottish law, an order issued by the Court of Session to stay or prohibit a person from an act presumed to be illegal or wrongful. It is similar to the injunction in English and American procedure. Consult Erskine, John, 'Institute of the Law of Scotland' (Edinburgh 1773; new ed., 1898).

INTERDICTION, in Scottish law, a process for protection from imposition of persons of imbecile minds. It is similar in process and effect to the American commission in lunacy. In Louisiana and Quebec the practice is similar to that of Scotland, these states having derived their legal system from the Roman law.

INTERESSE TERMINI, in law, the interest held by a lessee after the grant of the lease and before his actual entry. This interest has been held alienable at common law, and upon the death of the lessee it goes to his executors. Such an interest at common law, however, required an actual entry by the lessee to create an estate in him, but if the interest has been created by a conveyance under the Statute of Uses, the estate vests in the lessee at once without actual entry by him.

INTEREST ("it concerns" — the party in issue—originally an award of damages, later used to evade the anti-interest laws), a charge for the use of money, by custom computed annually, on a basis of so many out of each 100 units loaned; but without diminishing the capital. It is possible to pay interest without loss, because, under conditions now general, the borrowed money can be employed in productive industry, from which a return equal to or greater than the interest can be obtained; or because comfort, prestige, or moral advantages of many kinds are derivable, justifying the expenditure when enough is left. Such borrowing is now useful on the whole, because civilization has ingrained a self-restraint in the masses which makes them in most cases manage money soberly and prudently. But in the early ages this was not so, except in a few developed commercial cities: Babylon carried on business by interest loans, and even bottomry bonds on shipping; Tyre probably did so; the great Athenian commerce was built up entirely by it, as Demosthenes explicitly says, but the mass of people were not fit to have the use of money, had no remunerative employment for it, and borrowed it only to use in self-indulgence, or in desperation because any rate was a choice of evils. There was little property to pledge, and the security was mostly the debtor's person; foreclosure meant selling him for a slave, and the grievance which called for Solon's legislation was the debt-slavery of a large section of the citizens. Hence arose a violent prejudice against the system altogether, as immoral in itself; the law of Moses prohibited it between Jew and Jew; Aristotle says it is essentially immoral, because money cannot breed money (this in the age of Athenian commerce), and never was meant for any such use; the Christian Church inherited the reprobation from the Jewish, and for many centuries forbade its members to take "usury" (money for the use of money, that is, interest at any percentage), and the secular laws were correspondent. In England interest did not become legal till the time of Henry VIII, but had been actually practised for many generations, by legal fictions of partnership or breach of contract, etc.; previously it was in the hands of the Jews — who were so indispensable as financial agents that a Jew who was converted to Christianity had all his property confiscated — and later of the Lombards. The first English permissive statutes fixed 10 per cent as the legal limit that might be charged; early in the 17th century it was set at 5. No serious doubt of the power of governments to regulate the current rate of interest obtainable was entertained till Bentham wrote his 'Defence of Usury' in 1786, proving that the laws could not possibly have any effect; because if the legal rate fixed was equal to or greater than the current rate it could not work any change in it; and if less, holders of money would not lend without obtaining their price plus an insurance for the risk of legal punishment. The doctrine was violently disliked, and has not even yet overcome the determination of the mass to show their dislike of usury by statute, or their belief that they can affect rates; but in a few American States of late years the anti-usury laws have been abolished. Of course a legal rate is always provided in default of contract.

Interest is not a natural right, but a matter of law or contract. The holder of a note payable without stipulation of interest cannot claim any until the note has become due and remains unpaid; thenceforward it draws money at the legal rate. The United States pays no interest on its debts, except where bonds are issued specifying it.

The legal and contract rates of interest in the various States and Territories of the United States are as follows, the figures in each case representing the rate per cent: Alabama, legal rate 8, contract rate 8; Alaska, legal rate 8, contract rate 12; Arkansas, legal rate 6, contract rate 10; Arizona, legal rate 6, contract rate 10; California, legal rate 7, contract rate unlimited; Colorado, legal rate 8, contract rate 12; Connecticut, legal rate 6, contract rate 12; Delaware, legal rate 6, contract rate 6; District of

Columbia, legal rate 6, contract rate 10; Florida, legal rate 8, contract rate 10; Georgia, legal rate 7, contract rate 8; Hawaii, legal rate 8, contract rate 12; Idaho, legal rate 7, contract rate 12; Illinois, legal rate 5, contract rate 7; Indiana, legal rate 6, contract rate 8; Iowa, legal rate 6, contract rate 8; Kansas, legal rate 6, contract rate 10; Kentucky, legal rate 6, contract rate 6; Louisiana, legal rate 5, contract rate 8; Maine, legal rate 6, contract rate unlimited; Maryland, legal rate 6, contract rate 6; Massachusetts, legal rate 6, contract rate unlimited; Michigan, legal rate 5, contract rate 7; Minnesota, legal rate 6, contract rate 10; Mississippi, legal rate 6, contract rate 8; Missouri, legal rate 6, contract rate 8; Montana, legal rate 8, contract rate 12; Nebraska, legal rate 7, contract rate 10; Nevada, legal rate 7, contract rate 12; New Hampshire, legal rate 6, contract rate 6; New Jersey, legal rate 6, contract rate 6; New Mexico, legal rate 6, contract rate 12; New York, legal rate 6, contract rate 6, any rate on call loans of $5,000 and up; North Carolina, legal rate 6, contract rate 6; North Dakota, legal rate 6, contract rate 10; Ohio, legal rate 6, contract rate 8; Oklahoma, legal rate 6, contract rate 10; Oregon, legal rate 6, contract rate 10; Philippine Islands, no fixed rate; Porto Rico, legal rate 6, contract rate 12; Rhode Island, legal rate 6, contract rate unlimited; South Carolina, legal rate 7, contract rate 8; South Dakota, legal rate 7, contract rate 12; Tennessee, legal rate 6, contract rate 6; Texas, legal rate 6, contract rate 10; Utah, legal rate 8, contract rate 12; Vermont, legal rate 6, contract rate 6; Virginia, legal rate 6, contract rate 6; Washington, legal rate 6, contract rate 12; West Virginia, legal rate 6, contract rate 6; Wisconsin, legal rate 6, contract rate 10; Wyoming, legal rate 8, contract rate 12.

That these provisions are more the result of tenacious tradition than of any very exact reasoning is shown by their terms. Only in a few States has there been any recent attempt to keep down by law the rate of contractual interest to the rate actually current in the community; in the others, unspecified debts bear 6 to 8 per cent interest while the current rate is 5. As to the contract interest, 13 States forbid anything beyond the legal rate; while two — New York and Pennsylvania — allow any contract rate on "call loans" over $5,000.

The theories of interest, like most economic principles, are much disputed by economists. The chief theories are those of "abstinence," holding interest to be a reward of abstinence from using up the capital in enjoyment (a variant of this regards it as a result of the general appreciation of the present above the future); of "productivity," holding it to be the return for production by capital in the same way that wages are a return for production by labor; the combination of the two, regarding the return as fixed by supply and demand, the latter depending on productivity and the former on abstinence; and the "monopoly" theory, which considers it a toll levied on the product of labor by the capitalists who control the means of production.

INTEREST, as employed in psychology and pedagogy, is a term conveying at least two or three distinct ideas. The word also, in the vulgar sense, applies loosely to what is meant by personal advantage; as, for example, it is "to a man's interest" to obtain this or that. Etymologically, interest conveys the idea of a condition of being concerned about, or having a share in anything, in which sense also we find it used as a legal term. Perhaps its most definite meaning is that of the psychological law of interest, the law or principle that those elements of a past experience the most effective for recall are those which at the time of the experience received the greatest share of attention or aroused the highest degree of interest. Thus the great French psychologist, T. Ribot, uses the term. He remarks that "the influence of emotional states must be stated as a principle, but not as an exclusive cause. It is summed up in what Shadworth Hodgson has called the Law of Interest." ('Psychology of the Emotions'). The word interest, derived from the Latin *interesse*, literally "to go between," to make a difference, to concern, to be of importance, yielded in the course of a long evolution all the meanings of interest, both legal and psychological, as used in English.

Psychologically, interest may be broadly defined as the "consciousness which accompanies mental tendencies of any sort, so far as they terminate upon mental objects or stimulate to construction of them." (Baldwin). It is also from another point of view a phase of feeling, an intellectual feeling. It is always manifested by voluntary attention. Its opposite is the feeling of alienation and repulsion that accompanies a presentation of matter that is foreign to the experience of a student, or other person. By attention one understands the "conscious activity of the mind." Thus psychologically, interest and attention are closely allied *events*. Baldwin remarks that interest may be considered either as a stimulus or as a result of voluntary attention. Perhaps it is more precise to say that interest and attention are the subjective and objective aspects, respectively, of the same mental activity. This amounts to saying that the effective assimilation of new material into the course of experience is interest when viewed from the standpoint of the mental affections,— the emotion and personal attitude that accompany it. It is attention when viewed as the active outgoing of mental habits in grasping and in mastering the subject matter before one. All views of the relation subsisting between interest and attention acknowledge, at least, the intimate connection of the two; and it is precisely this connection which becomes significant in pedagogy. Like attention, interest as a state of the mind depends upon the proper balance of the old and new in experience. Neither interest nor mental activity appears to be the conditions of attention. Interest is either a general name for the subjective conditions of attention when ascribed to the object or it is used to designate a mood which accompanies all attention. Mental activity is really also bodily activity — a mass of sensations that comes from the contraction of muscles in different parts of the body. The contractions result from motor innervations which accompany attention. The interest of curiosity, the desire to know, may be defined as a primary form of interest, as distinguished from custom and habit and preference. Baldwin regards the former as being more of the nature of a stimulation to the intellectual function; the latter he regards as the resultant of a frequent performance of the function. This latter aspect, he tells us, is that which also underlies the popular use of the term in the plural, "interests" meaning one's prevailing and permanent disposition.

Where the material is almost entirely novel, there is an excess of stimulation if there is interest at all. The responsive power of the mind under such conditions is not infrequently overwhelmed and confused, and as a result we have sometimes discouragement or aversion. These truths have their importance for pedagogy, as well as for the psychologist. As a feeling we may well remind ourselves that interest is the feeling that something, the object of the feeling, concerns one. As the word aversion implies, on the other hand, there is in it a strong tendency of the mind to turn away and devote itself to a more congenial and rewarding object than the one which should concern it. Even when this tendency is overcome in part, it means divided, and consequently wasted, energy, as compared with unified, whole-hearted activity, where interest is naturally and directly sustained. On the other hand, what is thoroughly familiar denotes the mastered, the habitual. This state of affairs awakens tendencies that work automatically and mechanically. If there is also a new factor about which habits may play, these habitual tendencies will furnish a foundation for intense and concentrated interest. But, it is a matter of common knowledge, if there is no stimulation beyond that evoking the established habits, the result will be ennui, monotony, routine; the effect is that of walking in a treadmill where nothing new is achieved. A certain degree of difficulty, a certain amount of obstacle to overcome, enough to set the problem of a readjustment of habit, is necessary for sustained interest. The self must be allowed to proceed with thoroughly awakened powers; and this is impossible without a challenging difficulty. The fact just stated throws light upon the relation between desire, or interest, and effort, and helps to place the relation of the doctrine of interest to that of discipline. The doctrine itself is in pedagogy a sort of expression for a number of different motives. As long as a child lives in the mere present he is absorbed in his immediate concerns only. All its powers are directed and discharged upon the immediately present stimulus. There are for the child few if any ends, or conceived results, to be reached, after an intervening time, through the controlled adaptation of conditions as means. And whenever there is an end it usually lies in such a near future that but little thought has to be given to the management of the intermediate conditions. The state of immediate interest characterizes the play activities. In this sense only can one look upon interest as a form of amusement, a stimulus through the play-instinct to induce intellectual effort. When, however, more remote ends are to be reached by consistent and sustained maintenance of a series of acts that, of themselves lack immediate interest, but that are of interest because of their importance for the remoter end in view, we have mediate interest. Mediate interest being dependent on an idea, a purpose, a conscious aim, involves an intellectual interest in a way in which the emotional element accompanying direct absorption does not. The mediate interest is dependent upon the persistence of an idea, a conscious aim,-- and this involves the thought of the bearing of the immediately present upon the attainment of this end. Control of the activity and the source of interest, reside in what is conceived — a thing always physically absent when it is a thing and not in perception when non-physical. The remoteness of the end in time means of course the increase in the number of difficulties to be dealt with, one after another. Therefore we may be certain that the seriousness, the depth of the interest of the self in its objective — its aim — is continually confronted with tests. Under these conditions, while physical effort will go to the means for reaching the end, the moral and the inellectual effort will be directed to sustaining the idea of a purpose in such force as to give it motive power. All the elements of apparent conflict of interest and effort, with immediate attractiveness, immediate agreeableness, immediate pleasurableness, on the side of interest, while serious and important values are all on the side of effort — is what disturbs some well-meaning educators. Hence the situation has been completely misinterpreted in theories of education, with respect to both its moral and other higher implications. In this way interest has been regarded by some as inherently unworthy, objectionable as a factor; some appear to assume that it operates only as a temptation away from the objectively important. Identified thus with the attractive and swerving power of the immediately pleasurable and placed over against what reason shows to be really worth while, it has been the source of much misery to both pupil and teacher. Its logic is bad; and its results are worse. Logically, it implies that the objectively valuable end is totally devoid of interest, so that sheer effort of the will has to be relied upon as the sole motive for keeping the self in its right course — for keeping it struggling against the seductions of interest. The previous analysis it is to be hoped will reveal the fault of this conception. For in truth what sustains effort is not sheer appeal to will power, but interest in an end, an interest, both indirect, intelligent, and at times, even moral, as distinguished from that which is immediate, purely personal, emotional, sensuous. We do not mean to imply that some ends should be immoral; it is intended above to take cognizance of the fact that there is a realm of the morally indifferent. The genuine educational need is therefore not to eliminate interest, but to foster indirect interest, the interest that is not immediate but mediate. Yet it would be well to remember that immediate interest also has its claims: it remains a fundamental trait of all æsthetic and artistic life. In either case whenever a pupil becomes intensely and sincerely interested in an end which reflection holds up, the sense of separation between means and end tends to disappear from consciousness.

P., 'Über John Dewey's Theorie des Interesses und seiner Anwendung in der Pädagogik' (Halle 1901); Dewey, J., 'Interest as related to the Will' (Bloomington, Ill., 1896); De Garmo, C., 'Interest and Educa-

tion' (New York 1902); Ostermann, W., 'Interest and its Relation to Pedagogy' (Trans. by E. R. Shaw, New York 1899).

INTEREST, Relation of Capital to. See CAPITAL.

INTERFERENCE, *in physics,* a name applied to the mutual action of "waves" of any kind upon one another, a phenomenon by which under certain condition the vibrations and their effects are increased, diminished or neutralized. A wave, obiter dicta, in the sense of the word as here employed, should convey the idea of a "forward-moving form of motion" (like waves in a wheat field), and should not convey — in a way productive of much error in the past — a notion of a "forward-moving mass of matter." (Consult Mach, 'Popular Science Lectures' 1910). Motion, finally is a change of place; a transformation, changing of forms involving displacements; a new arrangement of parts in space is the main result of motion.

As a word, interference was formed on the false analogy of such words as "difference"; it was derived from *interfere,* which in the Latin original *ferire* conveyed the idea of a horse striking one foot or ankle against an opposite foot or ankle, while moving along. Thomas Young in 'Philosophical Transactions' (1801) first introduced the term and the idea underlying it into optical studies, when he employed it in his Bakerian lecture on the 'Theory of Light and Colours.' Since Young's time, the idea of interference has been extended so as to describe any kind of coming together of "waves," whether those of snow, sand, water, light, sound, heat or electricity; in short, wherever the wave-motions exhibit a collision. Interference may be observed when two different trains of waves come together upon the surface of water or any other liquid. Where the crest of a wave belonging to one system coincides with the crest of a wave of the other system, the elevation of the water surface is sensibly equal to the sum of the heights that the separate waves would have if each existed in the same place alone. When a crest of one of the waves coincides with the trough of another, the disturbance of the water surface is reduced, and the elevation (or depression) which results is equal to the difference between the elevation of one of the component waves and the depression of the other one.

The kinds of interference that are of the greatest practical importance in physics are those which occur among sound waves or among waves of light. The phenomena in these cases are ultimately of the same general sort as those observed upon the surface of water. A familiar result of the interference of sound waves is the production of "beats" when two or more trains of waves, having but slightly different wave-length, come together while the two are moving in nearly the same direction. This phenomenon is exhaustively treated in Helmholtz's 'Sensations of Tone,' and it also receives a more or less adequate treatment in all of the better works on physics.

The more familiar of the interference phenomena that are afforded by light are those which are observed in connection with soap bubbles and with very thin plates of transparent solids. Light, upon striking the soap bubble or the thin plate, is reflected toward the eye from both surfaces, and the trains of light waves that reach the eye from these two sources, since they have a slight difference of phase (which varies, moreover, from point to point of the bubble or the plate), interfere with one another so as to produce effects that are often very beautiful and striking. A soap bubble, when viewed by monochromatic light, often appears to be covered with dark striæ; the dark lines being due to the fact that at the points that appear dark the two trains of light-waves, coming respectively from the inner and outer surfaces of the soap bubble, nearly or completely neutralize each other. When the bubble is viewed by white light, we do not commonly see the dark striæ, their places being taken by bands of color. This is because the different colors that compose white light have different wave-lengths, so that at any given point in the bubble only a portion of the colors are destroyed by interference, leaving the remaining constituents of the white light to produce their full chromatic effect upon the eye. For further information consult Cornish, V., 'Waves of the Sea and other Water Waves'; the same author's 'Waves of Sand and Snow' (both Chicago 1915); Michelson, 'Light Waves and their uses' (Chicago 1903); the book of Helmholtz, mentioned; Herz, H., 'Electrical Waves' (New York 1915), whose experiments laid the foundation of wireless telegraphy.

INTERIM, in the history of the Reformation, the name of several compromises forced on the German Protestants by edicts of Charles V, especially that of 1548, regulating religious and ecclesiastical matters "in the meantime," till they could be decided by a general council. The *Ratisbon Interim* was drawn up in 1541 by a commission which included Eck, Bucer, Pflug, Gropper, Pistorius and Melanchthon. Many doctrinal points were smoothed over, but the differences in regard to the ecclesiastical power and the sacraments were too great to be reconciled. By the Protestants in general, the whole movement was looked on as a scheme to entrap them into a formal return to the Roman Church. In 1548 at Augsburg the emperor appointed Agricola, Helding and Pflug to prepare a new interim. It conceded to the Reformers communion in both kinds, and the marriage of priests. Great opposition developed in North Germany and the pact was revoked in 1552. Elector Maurice of Saxony secured the adoption of the *Leipzig Interim* in 1548, according to which the Protestant creed remained intact, with an admixture of the old ceremonial; the papal and episcopal powers were also recognized to a limited extent. This compact failed to reconcile a great number of the Reformers, and it was the cause of division among them. Consult Lindsay, T. M., 'History of the Reformation' (Vol. I, New York 1906–07).

INTERIOR, Department of the, one of the executive departments of the United States government whose heads are cabinet secretaries. The "home department," long existent in all European governments, was constituted in the United States by act of 3 March 1849. Its functions had been exercised by bureaus or officials of nearly all the other departments: patents, copyrights, public documents and the census belonged to the State Department; public lands, mines and judicial accounts, to the Treasury; Indian affairs, to the War Department; and pensions to the War and Navy, each for its own pensioners. By later laws the Interior was given charge of education, public surveys (including the Geological Survey; but the Coast and Geodetic Survey belongs to the Treasury), subsidized railroads, Territories, national parks and reservations, returns of public contracts made by several other departments, some charitable institutions in the District of Columbia, and a number of other matters. The Secretary makes an annual report of the number of public documents received and distributed. He has a salary of $10,000 and two assistant secretaries. All patents issued by the United States must be signed by him. The first Secretary was Thomas Ewing of Ohio. The list of secretaries since 1900 is Ethan A. Hitchcock of Missouri, James R. Garfield of Ohio, Richard A. Ballinger of Washington, Walter A. Fisher of Illinois and Franklin K. Lane of California. Besides the assistant secretaries and chief clerks, the Department of the Interior includes among its officials commissioners of Land Office, Pensions, Education, Indian Affairs, Patents, and directors of the Geological Survey, Reclamation Service and Bureau of Mines. In the annual report for 1915 the Secretary of the Interior calls attention to what he terms the "foundations of power" of the United States. The country possesses every mineral of importance needed in industry, and is the only country so fortunate. We produce 66 per cent of the world's petroleum, 60 of copper, 40 of coal and iron and 32 of lead and zinc. We can build a battleship or an automobile (excepting the rubber tires), a railroad, or a factory with the products of American mines and forests. To feed the soil we have plenty of phosphorus, some potash, and have learned to extract nitrogen from the air, having cheap hydro-electric power in abundance. We can produce all the grains, fruits, vegetables and fibres known to the temperate zone, and many tropical plants. And we have unlimited water power, besides two hundred and odd million acres of public lands; if we add Alaska, that is 400,000,000 more acres. We issue 200 patents a day to American inventors; of important patents granted by the United States since 1875, three-quarters are to American citizens. The great American desert, as we used to call it, is disappearing under the wise system that utilizes the money received from sale of public lands for irrigation works to reclaim the dry areas. The Secretary thinks the largest task awaiting our government is the proper dyking, damming and utilization of our rivers.

INTERIOR BOUNDARIES. See BOUNDARIES OF THE UNITED STATES.

INTERIOR DECORATION. Under the general designation of interior decoration are included all the various applications of the DECORATIVE ART (q.v.) to the adornment of the interiors of buildings. The subject comprises *monumental* interior decoration, which is largely architectural and has to do with the decorative treatment of the floors, walls and ceilings of important buildings; and *domestic* interior decoration, which has to do with the furnishings as well as the architectural treatment of rooms and halls in private residences. The decoration of hotels and clubs occupies a position intermediate between the two divisions, partaking of one or the other character according to the architectural importance of the building. In the first division we are chiefly concerned with the architectural design of the interior, with columns, arches, pilasters, entablatures, moldings, niches, vaults, domes, ceilings, wainscoting, panelings and pavements; with the arts of mural painting, decorative sculpture and carving, mosaic and inlay, and stained glass. In the second division these architectural elements are less conspicuous and there enter considerations of furniture, carpets, rugs, tapestries, hangings and wall-papers, and of the comfort and manner of life of the dwellers in the house. The fundamental principles of art are the same in both divisions, but the applications are widely different.

Monumental Interior Decoration; Methods and Resources.— In order to make the interior of a great building — as a hall, church or theatre — decoratively pleasing, the artist may employ the resources of pure form or of color, or of both together, as is most often the case. Anyone who has seen the interior of Grant's tomb at New York realizes that its decoration is wholly one of form; of architectural features and paneling, executed for the most part in white plaster. At the other extreme is the Sistine Chapel of the Vatican at Rome; an interior almost absolutely devoid of architectural embellishment, made glorious by the decorative painting of its walls and ceilings by the greatest artists of the Renaissance. But in general, form and color are combined, as in the great basilica of Saint Peter, near by; in the superb Camera della Segnatura by Raphael in the Vatican; or, to take a modern instance, in the gorgeous staircase hall of the Opera in Paris. Fergusson in his 'History of Modern Architecture' (Introduction, p. 15) draws an interesting comparison between the interiors of the Sistine Chapel and of King's College Chapel at Cambridge. The last named depends chiefly for effect on the richness of its structural and architectural features, the former on its incomparable frescoes. Which is the higher and nobler sort of decoration? The answer will vary according to the taste and point of view of the answerer, and still more according to the quality and success of the artist's performance with one or the other method. Fergusson considers the Sistine Chapel as exemplifying the higher type of decoration, but objects to figure-painting on the horizontal parts of ceilings. The Arena Chapel at Padua, painted by Giotto (q.v.), he considers superior in method to the Sistine, however inferior in performance and technic of painting. One element in our judgment of the two systems must inevitably be that of the more sustained, varied and intellectual interest inspired by noble mural paintings as compared with richness of architectural detail. The content of mere architectural detail is soon apprehended, owing to its dependence on repetition of similar forms, and its novelty of interest is therefore soon exhausted. See MURAL PAINTING.

The resources of interior decoration of a monumental character are, then, first of all architectural forms or (collectively) *membering;* secondly, carving and sculpture; thirdly, the use of fine or semi-precious materials of

rich natural color, such as marble, porphyry, onyx, highly polished woods and the like; fourthly, the applied arts of inlay and mosaic and the kindred art of stained glass; and fifthly, mural painting, which includes the painting of ceilings and vaults and ranges from the simplest harmonies of flat coloring on the various surfaces, through all varieties of painted ornament to the highest forms of allegorical, symbolic and historic painting. To these resources should be added the decorative treatment of the accessories and fixed furniture of the building, such as grilles and gates and railings in metal, pulpits, choir-screens and sedilia in stone and marble and wood, and other like essential features of the interior equipment. All these resources may be called into service in a single interior to produce almost overwhelming effects of richness and splendor, as in the original state of the church of the Divine Wisdom (Hagia Sophia, now the mosque of Aya Sofia) at Constantinople, built in the 6th century; contemporary descriptions of this interior, in prose and in verse, exhaust the resources of language in the effort to portray the glories of that marvelous edifice. The interior of the Camera della Segnatura at Rome, mentioned above; of the cathedral of Sienna; of Saint Mark's at Venice; of the Taj Mahal (q.v.) at Agra (India) and of some of the Mogul palaces of that country; of certain halls in the Alhambra at Granada (Spain); of the staircase hall and *foyer* of the Opera at Paris; of the Panthéon and parts of the Hôtel de Ville of that city; of the Public Library at Boston, Mass., and of the Congressional Library at Washington, D. C., illustrate in varying ways and degrees such combinations of architecture and the applied arts respectively in mediæval, Reniassance and modern times.

Historical Survey; Pre-classic Decoration. — Certain caves in France and Spain have preserved to us the remarkable efforts of primitive man to adorn these interiors with paintings of animals. (See ABORIGINAL ART). These date back probably to an antiquity of at least 25,000 years. Then follows a hiatus of many millenniums preceding the earliest extant Egyptian interiors of tombs and temples, with which historic art in interior decoration may be said to begin. In the temples the solemnity of pillared hypostyle halls and of the sanctuaries was relieved and enriched by pictures and bands of hieroglyphics, cut into the stone in outline or carved in low relief, and painted in brilliant colors. The pictures represent gods and kings, sacrifices and sacred vultures, with conventional ornament executed in the same way. The walls of the tombs were adorned with scenes from real life, sometimes painted on plaster, sometimes cut in low relief on the stone (Tomb of Perneb in the Metropolitan Museum, New York). As ancient as some of these Egyptian works are the remarkable paintings of walls in Crete, especially at Knossos; while somewhat later in date (9th to 6th century B.C.) are the decorations in the palaces of the Assyrian kings. Low relief pictures on alabaster or limestone slabs formed a high wainscot in the halls of these palaces; above were probably borders in encaustic tile and tapestries or other hangings. In places even the pavements were of alabaster carved with ornaments in low relief.

The Classic Period.—Of the Greek interiors almost nothing has survived to our time; all the "restorations" shown in books and models are conjectural. We know from literary sources that mural painting was practised; the Stoa Poikile at Athens was a public colonnade whose wall behind the columns was covered with such paintings. At Olympia there was found a beautiful fragment of decorative pavement executed in hard stucco in black and white. Since color was freely used on the exteriors of temples it is probable that the interior columns and walls were painted and the wooden ceilings richly painted and gilded, perhaps paneled somewhat like the stone ceilings of the exterior colonnade or pteroma.

It was the Romans who, of all antique peoples, developed interior decoration to its greatest splendor by recourse to new methods and materials and processes. The Roman decorative system was that of a dress or sheathing or facing of fine material applied to a massive core-construction of coarser materials, such as rubble, concrete or brick. This was faced with stucco, or sheathed with marble and adorned with columns, niches, recessed arches, moldings, entablatures and panels, for which provision was made in the more massive primary construction. Columns were of polished granite, porphyry or marble; capitals and entablatures were richly carved; there was much ornament of stucco molded in relief and brilliantly painted, and ceilings and vaults were deeply paneled, with rich ornaments in relief painted and in parts gilded. The lower parts of the walls were wainscoted with precious marbles, and the floors were of marble in patterns of various colors or in mosaic of *opus Grecanicum*. (See MOSAIC). The vastness of the Roman interiors of temples, baths and basilicas unencumbered by columns, and the majesty of their lofty vaulted ceilings, produced effects of internal grandeur never before dreamed of, which were greatly enhanced by the splendor of the materials employed. The Pantheon remains to-day a marvelous example of this splendor, though deprived of the former enrichments of its majestic paneled dome. The brilliant wall paintings of Pompeii (q.v.), the Pompeiian and Roman painted reliefs in stucco, and many Roman mosaic floors, preserve for us examples of Roman interior decoration of a less monumental sort.

The Mediæval Styles.— With the fall of Rome, the leadership in the arts passed to Constantinople, where the Byzantine style rapidly developed in the 6th century to its culmination in Hagia Sophia, the church of the Divine Wisdom. It was pre-eminently a style of interior decoration, not of external splendor. Deriving from Roman precedents the system of massive vaulted construction with surface facing of marble sheathing and applied decoration, it introduced two new and transcendently important elements — the dome on pendentives and the use of pictorial and ornamental mosaic in brilliant colors on a gold ground, to cover all vaulted surfaces. Fine surface-incised carving was used sparingly and effectively, but the main effect was of rich and harmoniously-blended colors upon every visible surface. Fresco-painting (see FRESCO) was employed in some cases instead of mosaic on walls and vaults, at least in the later churches. The Byzantine mosaic-workers and other artists found wide employment in Italy, and when in 1047 the Venetians set about the reconstruction of the church of Saint Mark, it was built upon the model of the church of the Apostles at Constantinople, largely by artificers from that city. Though much smaller than Hagia Sophia, and though some of its mosaics are of a much later age than the 11th century, it is to-day one of the richest and most splendid interiors in the world. Of much earlier date are the two basilicas of San Apollinare at Ravenna (6th century) with fine mosaics, those of San Apollinare Nuovo being particularly impressive. The baptistery of the Orthodox and the domical church of San Vitale at Ravenna also offer striking examples of Byzantine interior decoration in marble and mosaic.

The Romanesque period in western Europe, from the 8th to the mid-12th century, produced little of importance in interior decoration except in Venice as just noted, and in Sicily where a blending of Oriental and Byzantine influences has left to the world a number of remarkably beautiful and impressive interiors in churches and chapels at Palermo and in the neighboring cathedral of Monreale. The pavements of these are patterned in colored marble, the walls wainscoted with marble crested with Arabic patterns, the walls and domes and apses glow with impressive symbolic pictures in mosaic, and the timber ceilings were painted in brilliant colors The baptistery of Florence (10th century) and the neighboring church of San Miniato are exceptions to the general rule of severity of interior effect of the Romanesque architecture.

For the remarkable styles of interior decoration of the Arabs, Moors and other Mohammedan peoples — styles in which pictorial representation and sculpture were excluded by religious prejudice and geometric and conventional ornament in brilliant colors in plaster, tiles and inlay developed to their utmost splendor during the Middle Ages, see MOHAMMEDAN ART.

With the development of Gothic architecture, first in France, later in northern and central Europe, and finally in Italy, wholly new resources were brought to the service of interior decoration. Structural forms were multiplied and enriched, to enhance the decorative effect of the lofty vaulted naves and aisles. To the splendor of clustered shafts, grouped moldings, carved capitals, molded vaulting-ribs and intricate traceries were added symbolic sculptures and grotesques, and color was introduced in the blazing glory of the stained glass windows. To a limited extent also painting was resorted to in certain parts of the architecture and even of the sculpture, an decorative pavement-tiles in browns, blacks, dark reds and yellows were used with discretion on the floors of choirs and chapels; but the chief color effects were in the windows, whose brilliant hues tended to kill the soberer tones of painted walls and moldings. Mosaic and marble were not favored outside of Italy, and the vaults were seldom painted at all. The English interiors, less lofty and majestic than the French, were on the other hand far richer in decoration, with multiplied complexities of shafting in black Purbeck marble, finer and more numerous moldings, and, above all, magnificent vaults in complex patterns of vault-ribs. In Italy, in contrast with western and northern Europe, the mediæval builders of the Gothic period depended upon color rather than architectural membering for interior effect. They often painted both the walls and the vaults; splendid inlays of black, red and white marble adorned the floors; mosaic was frequently applied to restricted places or features, and the fixed furniture was of great decorative magnificence. Stained glass, however, was not much used; the Italian windows were small and far apart, and offered no such field for blazing transparent color as the clear stories and aisle windows of the North. The 14th century witnessed the culmination of this Italian mediæval art, above all in Florence, Assisi, Padua and Sienna. The mural paintings of the chapels and cloisters of Santa Croce and Santa Maria Novella at Florence, and the works of Giotto and his followers in Florence, Assisi and Padua are unsurpassed for pure decorative propriety and richness. (See GIOTTO; MURAL PAINTING). The "Upper" and "Lower" church of San Francesco at Assisi offers the most complete and perfect example of consummate interior decoration effected solely by the brush of the painter without any aid from architectural embellishments, to be found anywhere, with the sole exception of the Sistine Chapel of the Vatican at Rome.

Renaissance Decoration.— The Renaissance ushered in a new age and a new spirit in art. Not only were the fine arts thenceforward no longer confined almost exclusively to the service of the Church, but they were also transformed by two influences — a new and enthusiastic study of nature in all its aspects, leading to a new realism previously unsought; and a new inspiration from the arts and culture of antiquity. There was great increase of private luxury, and a marvelous broadening of the scope of painting and sculpture as well as architecture. Palaces were made as splendid as churches, and churches were adorned with new splendors in marble, stucco, painting and gilding. The dome became the dominant internal feature in church design, and often received a specially rich decoration of paneling and painting or mosaic. Delicate relief-ornamentation in stucco was combined with color, after ancient Roman models. Mural painting reached its highest development. Ceilings, whether vaulted or horizontal, were treated with especial magnificence, with rich paneling or painting or both combined. Rome especially abounds in splendid examples of this consummate art of the 16th century, as in the Loggie (arcades) of the Vatican, the Camere or Stanze (apartments) of that palace, the Villa Madama, and of course the incomparable Sistine Chapel. The vaults and dome of Saint Peter's and many other ceilings are noteworthy; while in Venice the walls and ceilings of the hall of the Great Council and of many other superb rooms display the master works of Titian, Tintoretto, Paul Veronese, Palma the Younger and others of the Venetian masters of oil painting. (See article PAINTING). With the close of the 16th century and throughout the 17th, decorative art declined — not in splendor but in taste. The love of display, the toleration of sham, the abuse of stucco, of gilding and of strong-colored marbles, and the introduction of theatrical and attitudi-

nizing sculpture, led to great extravagance and excesses of effect, destructive of real dignity and solemnity. Much of the interior decoration in Saint Peter's and nearly all that in the Jesuit churches of the 17th and 18th centuries, both in and out of Italy, is of this meretricious character. In Germany this "Baroque" style of interior decoration was especially riotous and uncontrolled by architectural propriety, though often amazingly clever and effective. In France the Renaissance style, introduced by Italian artists at first, ran a somewhat similar course, but never reached the extremes of artistic extravagance noted in Italy and Germany. Church interiors were much more severe, more sparing in applied decoration, and retained much more of structural expression and truthfulness. French palace decoration received under Louis XIV and XV a peculiar progressive development, making much use of white and gold, and of delicate though increasingly fantastic and capricious detail, as will be later noted. Under Louis XVI and under Napoleon ("First Empire") the tendency toward fantastic originality of detail was reversed, and interior decoration became more and more classic, restrained and finally severe.

The 19th century witnessed the almost total eclipse of true and sincere work in interior decoration, as in all the arts, for at least the first half of its course. Under Napoleon III ("Second Empire") there began in France a notable revival of all the arts, and, partly through French influence, this revival gradually made its appearance in other countries. The progress of archæology, the development of machine-manufacture, the immense expansion of commerce and industry, all tended, however, to lead artists astray and to hamper the development of original creation. On the other hand, the multiplication of schools of art and of museums and the growth of wealth and taste have given the arts a new stimulus and new opportunities. Among notable interiors of the last century in Europe may be mentioned in London the Houses of Parliament and the mosaics of Saint Paul's Cathedral, in Paris, the stair hall and foyer of the Opera, the stair hall and Salle des Fêtes of the Hôtel de Ville, and the mural paintings in the Panthéon. Examples in the United States will be noted later.

Present-Day Monumental Interior Decoration.— Outside of the United States, which form the subject of a separate section of this article, interior decoration has followed the general movement of modern art since 1900. As to style, two distinct currents are observable; one conservative and classic, tending to the revival or imitation and development of old-time traditions; the other, revolutionary and romantic, seeking new forms and methods of expression and striving to break away from tradition. These currents are equally discernible in architectural decoration and in decorative painting, and appear in the interior decoration of all the European countries in varying degrees. The decorators of the first group are subdivided broadly into the classicists and the mediævalists, according as they seek to reproduce the decorative effects of Greek or Roman types on the one hand or of Byzantine, Romanesque or Gothic art on the other. The multiplication of books, prints and photographs of historic art, the ease of modern travel and the greatly increased mechanical and material resources of our time have made such revival and imitation perfectly practicable and even rational. The practice in the best work is not to copy, but to design upon the basis of a thorough mastery of the principles and methods of the historic styles. The decorators of the second group, while they must of necessity start with something of the knowledge and experience accumulated by the centuries, consciously strive to avoid any suggestion of the forms, combinations and types of the past, and to devise in their place new and original media and forms of artistic expression. The movement of which their efforts are the result began in Paris near the end of the last century, and made a sensational appeal to the world-public in the great exhibition of 1900. It has been variously called "Art Nouveau" (New Art), "Moderne Kunst" (Modern Art) and "The Secession," and has been carried to the furthest extremes in Germany and Austria, especially in Bohemia. But its most notable productions have been rather in domestic interiors and the minor arts than in monumental interiors, and these for the most part in hotels, restaurants, theatres and other places of amusement rather than in churches and the more stately works of interior design.

Modern ecclesiastical interior decoration has generally followed, more or less closely, the traditional styles of the past; either the Gothic (or less frequently the Byzantine or the Romanesque), or the Italian Renaissance. Mural painting is less often depended upon than architectural enrichment and conventional ornament, the richest decoration being bestowed upon the chancel or choir or "Sanctuary" of the church.

Domestic Interior Decoration.— The purpose of the interior decoration of a dwelling is to effect a harmonious combination of form and color not only in the architecture of each room and hall, but also in its furnishings and accessories, with due reference to the size and scale of the house, and to the comfort, convenience and tastes of the occupants. The house as a whole must present a harmony of effect, and each room must present a pleasing harmony within itself. The house-interior differs from the interior of a great hall, church or theatre not only in its much smaller scale, which brings every feature of its decoration within a few feet of the spectator's eye, but also in its more intimate and personal character. The interior of a church or great public building, moreover, is designed to impress and please a miscellaneous public, no member of which occupies it for more than a few hours at a time; and it must be decorated in a manner looking to permanence, in a style which will not soon lose its public appeal. In the house, on the other hand, quite other conditions must be met. The house is to be lived in; its decoration must be the constant companion and environment of its occupants. These, moreover, are a family, for whose personal pleasure the decoration is designed, and their personal tastes must of necessity control the design. With a change of occupancy, all too frequent in our modern shifting society, it is likely that much or all of the decoration will be changed. Hence domestic interior decoration is at once more personal and less permanent than the greater art of monumental decoration.

House decoration is in all countries subject to divers influences. There are in the first place the architects, who in designing the residence not only shape its plan, construction and exterior, but also give to certain parts of its interior a definite architectural character by the treatment of walls and ceilings, window-trim and door-trim, wainscots, chimney-pieces and cornices. Generally their work stops there, and the householder calls in a "decorator" to make the empty architectural shell more ornate and more habitable. The decorator directs the painting and gilding of certain parts, devises a color-scheme for each room and selects furniture and draperies, rugs and tapestries to complete the scheme. The owner may or may not have a voice in the production of the *ensemble*. He may be himself an art connoisseur, possessing fine furniture, rugs, hangings, bronzes and bric-a-brac which the decorator must work into his scheme. Or he may be a *nouveau-riche* with plenty of money and no artistic training, in which case he gives the decorator a free hand. It is largely to this latter sort of householders that we owe the rise of a large class of commercial decorating concerns, which take contracts for the entire decoration of a great house; and also of another large class of individual decorators who combine a keen sense of commercial advantage and acquaintance with market costs, with just enough artistic knowledge to impress their clients. It is rarely that a discriminating client, distrustful of his own taste and judgment, has the courage to call in a truly great artist to beautify his house. Such an artist may generally be trusted to seek his client's interest, to work in sympathy with his particular problem and to subordinate questions of mere personal gain to the higher artistic ends of his work. If the house be one of great architectural importance, he will work in conjunction with the architect. It is always desirable to establish some such collaboration at the very outset of any important architectural undertaking, whether public or private. The only hope of suppressing the charlatanism and the commercialism that infest the practice of house-decoration to-day lies in the gradual raising of the popular standards of taste. In this respect there has been undoubted progress in the last 20 years and further progress may be looked for in the future. The greatest enemy of good taste in the home is in all countries the love of luxury and display, and the constant desire to imitate the splendors of houses more costly than one's own. The passion for "period" rooms — that is, for rooms each decorated in the fashion and style of some bygone art-period — is evidence of a common misdirection of taste; it is an affectation which, it is true, may in competent hands produce highly artistic results; but it more often converts the home into a sort of museum of imitations. Simplicity and restraint are too often sacrificed to display; but there is observable in the best domestic interiors of our time, both in this country and abroad, an increasing recognition of the value of simplicity, of quiet dignity and of that harmony of form and color which gives the impression of restful domesticity.

The "periods" most frequently employed in elaborate house interiors are four from the French Renaissance and four from the English Renaissance. The *Louis Quatorze* style is that which was developed under Louis XIV (1643–1710) in the palaces of Fontainebleau and Versailles and in the many sumptuous residences of the nobility of France. White and gold predominate; the walls are paneled in gilt framing-moldings; a richly ornamented coving, with or without a bracket-cornice, frames the ceiling; the doors and wainscot in rectangular paneling are adorned with delicate painted ornaments. The marble fireplace supports a huge mirror in a sumptuous gilded frame. The seat-furniture of gilded wood is upholstered with specially woven tapestries, and the cabinets, tables, etc., are of mahogany or other dark wood inlaid with brass and tortoise-shell ornaments. The tapestries, curtains and hangings are of richly patterned materials of formal design. In the *Louis Quinze* style (under Louis XV, 1715–74) all rectangular and formal lines disappear; curves predominate in all panels, in the chimney-pieces and in all the lines of the furniture. Paintings of Cupids and of pastoral scenes occupy panels in covings and sometimes on walls, and the ornaments are of shells, scrolls and foliage of singularly ragged and contorted forms, yet (in the best examples) so delicate in execution and so playful in line as frequently to disarm criticism. The style wholly lacks structural expression and dignified restraint, but lends itself to the intimacy of a lady's boudoir or the abandon of a ballroom. The style of *Louis Seize* (Louis XVI, 1774–89) represents a reaction from these extravagances. The swaying curves disappear, structural propriety reasserts its claims; a delicately-refined severity of line is observed. Nearly all the furniture is of gilded wood with specially-woven upholstery, the gilded brasswork trim of the larger furniture is almost Greek in its purity of detail, and wreaths of flowers replace the restless foliage and scrolls of the preceding style. The *Empire* style followed, with dark, almost sombre draperies and massive furniture of dark wood, built on Roman lines.

The two earlier English periods — the *Elizabethian* and *Jacobean* are not always easy to distinguish. Both employ high wainscoting in wood, flat relief "strapwork," open work wooden balustrades, flat plaster ceilings with "all-over" paneling and ornaments in relief. But the Jacobean has none of the Gothic reminiscences that are met with in the Elizabethan; it employs pilasters and other classic details and especially the *gaine* or sheath-shaped pilaster, and the Jacobean chimney-pieces and furniture are more elaborate than the Elizabethan. The *Georgian* styles are those various phases of the English classic Renaissance which were outgrowths of the Italian Palladian influence of Inigo Jones, Wren and Gibbs; they are specially notable for a certain sober dignity and formality of detail, with richly carved woodwork, and constitute the parent style of our own Colonial. The *Adam* style, named from the Adam brothers, Robert and James, belonged to the closing period of the 18th century, and is the counterpart of the French *Louis Seize*; notable for delicate detail particularly in the plaster work and furniture.

Interior Decoration in the United States. — During the Colonial and early Republican periods the interior decoration of our few public buildings followed Georgian and Adam precedents, depending almost wholly on painted wood and white plaster. There was almost no color employed, and we possessed no mural artists capable of monumental decorative painting. There followed in the 30's and 40's a period of Greek revival, producing cold but dignified interior effects in some cases, but always without the aid of color. The earliest efforts at decorative color in public buildings seem to have been in New Orleans, where a nephew of Canova adorned the rotunda of the Hotel Saint Louis with colored panels and medallions in painted stucco-relief, and a French artist decorated the Opera House in rather staring colors which still remain. Shortly after this Brumidi, a second-rate Italian mural painter, with an assistant, Castigini, was employed in 1855 to decorate the drum and dome of the National Capitol with allegorical paintings, and continued to labor on this commission until his death in 1880. But the real beginnings of American decorative painting date from 1876, when the late John La Farge was entrusted with the interior decoration of Trinity Church in Boston, then approaching completion under the direction of its chief architect, Mr. H. H. Richardson. La Farge's work consisted in the designing of the entire color-scheme of the interior, including the flat coloring and the conventional ornament, as well as the mural paintings of religious subjects. Assembling a small corps of enthusiastic young artists — many of them since then famous — all inexperienced like himself in such work, and compelled to work in a hurry under every possible embarrassment, he achieved a triumphantly successful result, which profoundly influenced decorative art in America. His groups of 'Christ and the Woman of Samaria' and 'Christ and Nicodemus' are notable works, and launched him on a career that placed him at the head of American decorative painters. His "Ascension" in New York (church of the Ascension); his other religious paintings and some magnificent windows in various churches (among these windows being three in the Saint Paul's Chapel of Columbia University), and his allegorical paintings in the Capitol at Minneapolis and Court House at Baltimore, are all works of great artistic value in themselves, not merely as pictures, but as truly decorative elements in the interiors they adorn. Meanwhile (about 1874) the late William Morris Hunt had painted directly on the walls of the Assembly Chamber of the Capitol at Albany two vast and impressive allegories — 'The Discoverer' and 'The Flight of Night.' Unfortunately these have been sacrificed to structural alterations in the building.

During the period 1876 to 1886, the artistic awakening started by the influence of the Centennial Exhibition at Philadelphia had spread in a remarkable manner through the nation, and not only the architecture but all the decorative arts and industries had been transformed. Strong artistic personalities began to emerge; it became possible to produce in our own cities mosaics, carvings, metalwork and stained glass of the highest quality. Not only public bodies charged with the erection of State capitols, city halls, court houses and public libraries, but also private corporations building theatres and hotels began to realize the importance of entrusting the interior decoration of such buildings to great artists, and the wealthy builders of great houses followed their example. Very important was the influence of the Columbian Exhibition at Chicago (1893), in which many artists were employed to decorate parts of the buildings with paintings; but still more important was the work done about 1895 in two library buildings, the Public Library at Boston and the Congressional Library at Washington. In the first-named the great French mural painter, Puvis de Chavannes, adorned the staircase hall; the late Edwin A. Abbey, the loan-room, and John S. Sargent, the second floor corridor. The three works are in wholly different styles: the first, in light pale tones, is purely mural (see MURAL PAINTING); the second is almost purely pictorial in brilliant colors; the third is *sui generis*, the most original, mystically symbolic and magnificent decorative work in the country, representing by an extraordinary series of compositions the great religious conceptions that have come from the East and the development of Christianity. This work has been only recently completed. The Washington decorations — of stairhall, corridors and reading-room — are by a large group of painters — Blashfield, Vedder, Reid, Dodge, Walker, Pearce and others — very varied in treatment, partly historic, partly allegorical, producing on the whole a powerful impression of refined beauty, enhanced by the dignified decorative architecture of the interior, the work of E. P. Casey, and decorative statues by Adams, French, Bartlett and others. The Criminal Court building in New York, and later the Appellate Court in the same city, the Walker Art Gallery at Brunswick, Me. (Bowdoin College), the new State Capitol at Madison, Wis., and a long list of public buildings and churches throughout the country, the library of the University Club and several great hotels in New York, and the Great Hall of the New York City College, possess decorative paintings by E. H. Blashfield, Kenyon Cox, Edward Simmons, H. Siddons Mowbray and others of the artists named, and by others whom there is not space to enumerate.

The most notable example of American ecclesiastical decoration, with the exception of Trinity Church in Boston, is the church of the Paulist Fathers in New York, in which Mr. W. Laurel Harris, with the assistance of other artists, has for some years been engaged upon an elaborate and highly effective scheme in which mural painting, stained glass and mosaic are combined in a highly impressive manner.

As already observed, the architects and sculptors as well as the producers of mosaic carving, decorative stucco-work and metalwork, have all shared in the artistic revival and contributed to the success of the interior decoration of both public and private buildings. In the early 80's a group of men and women in New York calling themselves the "Associated Artists" collaborated in decorating the company rooms of the Seventh Regiment Armory and the charming little Madison Square Theatre, with draperies, embroideries, mosaic, metalwork and carved woodwork, upon quite original lines apart from classical traditions — a veritable

American *art nouveau*. For a number of years decoration of this sort, by color and ornament and effects produced by novel treatments of surfaces in wood, plaster, glass, stuffs, hangings, mosaic, marble and onyx, was the most characteristic form of decorative art in the United States. The greatest artist in this line was Mr. Louis C. Tiffany, who has developed entirely new products in glass, of great artistic splendor, both in decorative stained glass windows and in exquisite objects of small size, together with the arts of the mosaicist and inlayer. Mention should also be made of the decorative work, chiefly ecclesiastical, of the Lamb family in New York, in stained glass, mural painting, etc.; of Mr. Friederang's work in tempera and true fresco; of the beginnings made in tapestry-weaving, and of the great advances in recent years in decorative furniture, draperies and metalwork in the United States. And the great art of monumental interior decoration with the aid of mural painting, although for a long time the great success of the works in Trinity Church, Boston, and in the Albany Capitol, already alluded to, remained almost without fruit, has since made such rapid progress that in this field the United States has no longer any occasion as formerly for mortification at the scarcity of notable examples.

The lesser art of house decoration advanced at first more rapidly than the major art sketched above. The "Centennial" at Philadelphia opened the eyes of multitudes to the possibilities of beauty in the home through the harmonious combination of artistic draperies and furniture, and revealed especially the marvelous decorative fabrics and products of Japan. The first results were, no doubt, such as would arouse wonder and amusement to-day, but they were the sincere if blundering expression of a newly awakened artistic hunger. Under all the handicaps of commercial exploitation, inadequate training, and, above all, the absence of an artistic environment and inheritance such as Europeans enjoy, the arts of domestic interior decoration have made steady progress. Handwork and artisanship have been stimulated by guilds and exhibitions; artistic manufactures, such as the weaving of brocades, rugs and hangings of genuine artistic value, and the making of artistic furniture (see FURNITURE), have all been raised to a high plane of excellence. The architects of our houses are now in taste and competence the equals of their European confrères, and give to the interior design quite as much attention as to the exterior. Most important of all, the general level of taste of the public has been materially raised. Museums of fine and applied art, schools of decorative design, exhibitions, lectures and books on decorative art, have been greatly multiplied. The two great defects of the American taste in this field are, first, an often undiscriminating love of splendor; and secondly, a tendency to follow passing fashions and fads in decoration. Simplicity and repose are often sacrificed to richness and display. "Period" decoration and textual reproductions of historic styles, well enough in their way in certain cases and in moderation, militate against a more natural, personal and original expression of taste. But there is no denying that the artistic quality of even this sort of decoration has been steadily improving, and there is hope that with the maturing of our national character under the sobering effects of the World War, there will grow up in this field a national art having dignity, restraint, propriety and domestic expressiveness, appropriate to the American character and life.

Professor of Architecture, Columbia University.

INTERJECTION, a word thrown in to express some sudden emotion or passion; an exclamation; e.g., ah! alas! ouch! d—n! They are hardly considered parts of speech, and never form grammatical parts of a sentence; and seem more akin to the sounds uttered by the lower animals than to articulate language. For attempts to read other meanings into them consult Delbrück, 'Grundfragen der Sprachforschung' (Strassburg 1901), and Paul, 'Prinzipien der Sprachgeschichte' (4th ed., Halle 1909).

INTERLAKEN, ĭn'tĕr'lăĸ-ĕn ("between the lakes"), Switzerland, village in the canton, and 26 miles southeast of the town of Berne, one mile southeast of Unterseen, beautifully

situated near the left bank of the Aar, in the valley of Boedeli, between the lakes of Thun and Brienz. It contains a beautiful old castle and numerous hotels. It is visited annually by 80,000 to 100,000 tourists. Pop. about 3,750.

INTERLOCKING DIRECTORATES. A term used to designate the method by which the interests of many companies normally in competition are controlled by the election into their directorates of a few men acting in the interest of the combination to which they belong. Obviously, the success of the interlocking directorate system is predicated upon a certain betrayal of trust toward the individual company which the director is expected to serve with singleness of purpose, for he is placed there by the combination to serve the latter's interests. In a recent official investigation it was shown that a large steel manufacturing concern was the owner outright of several railroads, and the directors of the steel company were also directors in 29 other railroads, operating in the aggregate more than half the railroad mileage in the United States and in 12 of the largest street-railway companies. Control was thus exerted over the purchasing departments of all this great body of steel users, and, of course, in the ultimate interest of the steel company, and not of the railroads which these directors were intended to serve. The control of this steel company was traced also in a number of gas, oil and water companies, and in telegraph and telephone companies, large users of iron and steel products, through the same system of interlocking directors, and it was shown that the assets of the companies thus controlled in the interest of the steel company totaled the prodigious sum of $16,000,000,000.

The reaction of public opinion to these disclosures was so prompt and vigorous that one of the largest banking houses in the country voluntarily withdrew its members, men of the highest financial standing, from upwards of 30 directorates of railway, industrial and banking concerns. The system is now thoroughly discredited, and the unadulterated responsibility of the director to his individual company has been emphasized both in legislation and by the courts.

INTERLOCKING SIGNALS. See BLOCK SIGNAL SYSTEM.

INTERLOCUTORY JUDGMENT. See JUDGMENT.

INTERLUDE, a light entertainment given between the parts of another, usually between the play and the after-piece. The term also designates a particular form of early English dramas occupying a place intermediate between the miracle plays and moral plays. In church music, the interlude designates a short melodious phrase played between stanzas. Consult Collier, 'History of English Dramatic Poetry' (Vol. II, London 1831), and Ward, 'English Dramatic Literature' (Vol. I, ib. 1875).

INTERMARRIAGE, marriage between persons of the same family or at least between persons closely related by blood. From a very early period we find traces of a general belief that such marriages were generally followed by degenerate children. Thus the deterioration of the American negro, of the Cretins, the Marrons and the Cagots of Europe is laid to this practice. Such an opinion, however, may be refuted by adducing the Jewish race in which intermarriage has not led to this result, the good physical condition of several Indian tribes despite their common practice of intermarriage and the flourishing condition of many native tribes of India. (See BREEDING; CONSANGUINITY; MENDEL'S LAW). Consult 'New Encyclopedia of Social Reform' (New York 1910).

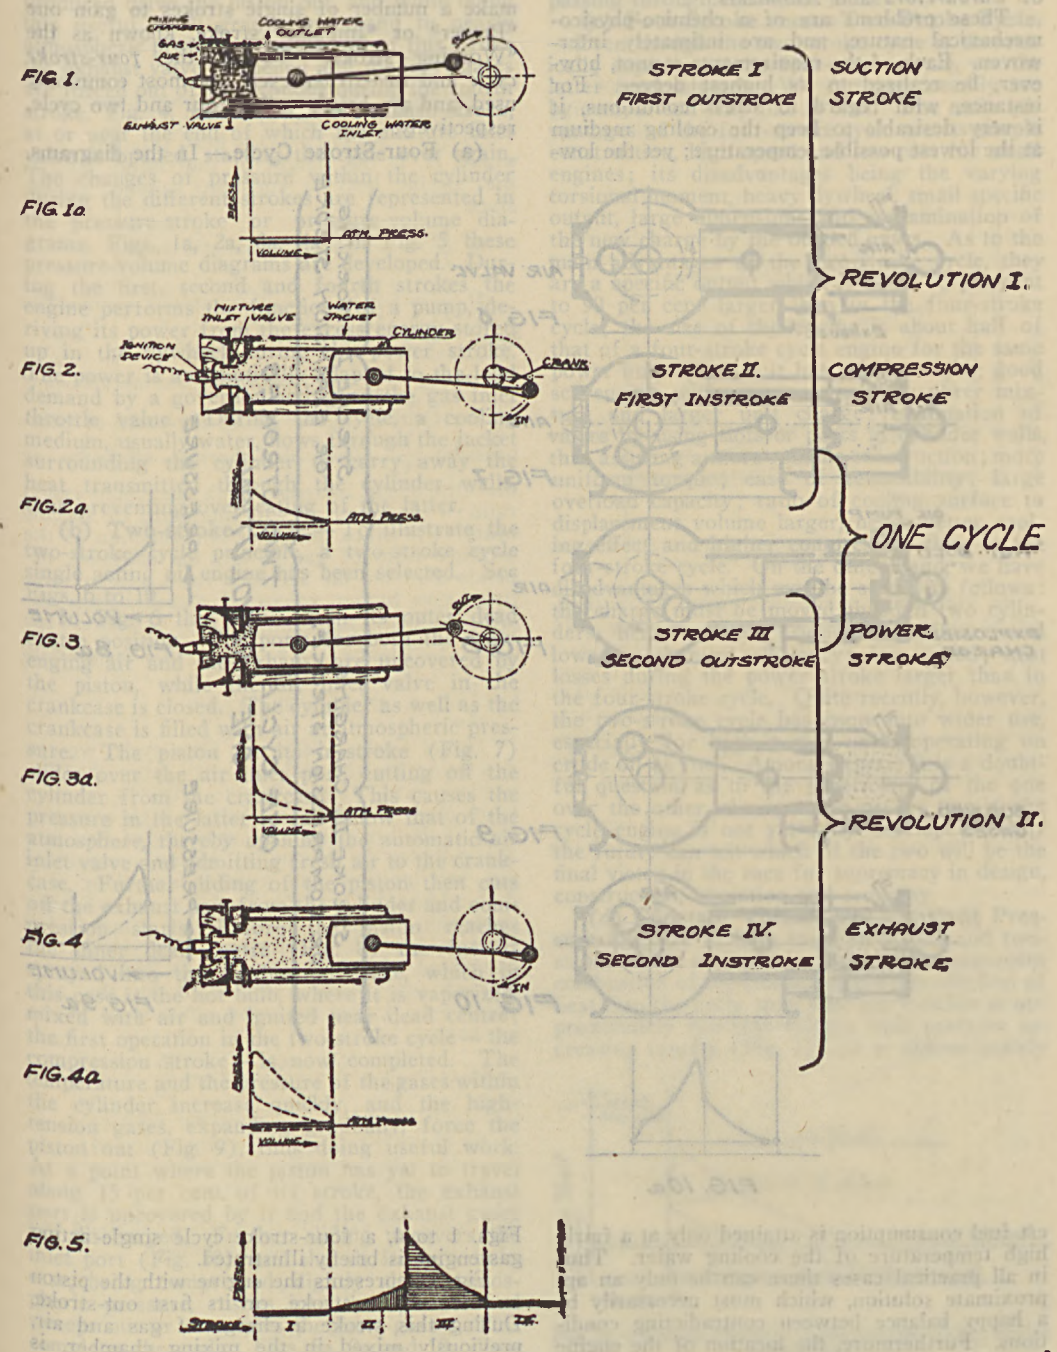
INTERMEDIATE STATE, *in theology,* is the presumed condition of the soul between death and resurrection. As nothing definite is known — or can be known — with regard to the progress of the human soul after death, practically all systems of religion have developed more or less elaborate theories on the subject. In Christianity there are two broad lines of cleavage — that of the Protestant side which believes that "The souls of believers are at their death made perfect in holiness, and do immediately pass into glory" (answer to Question 37 in the Shorter Catechism); and that of the Roman Catholic faith, wherein the view is held that there is an intermediate state (Purgatory) between or antecedent to heaven and hell. In this state, it is believed, the soul awaits and is gradually prepared for its final destiny. This belief is also held in the Greek Catholic or Orthodox Church, while it is not admitted by Protestants. Indications can be drawn from Scripture that at death the soul passes into some state of weal or woe, and that this state is not final.

INTERMEZZO, a dramatic interlude, consisting either of an instrumental or vocal piece performed between the acts. Intermezzi were features of early Italian drama and opera, and gradually developed their own independent form as Opera Buffa, which were later given separate performance, the ballet divertissement thereafter serving as intermezzi for grand opera. Consult Grove, 'Dictionary of Music' (Vol. II, London 1910).

INTERNAL COMBUSTION ENGINE.

I. Definitions.—An energy transformer, which converts chemical energy stored up in solid, liquid or gaseous combustible matter into heat and then into mechanical work, is called a *Heat Engine.* The heat is produced by the combustion of the fuel in air, and if this combustion takes place within the cylinder of the engine itself, the latter is generally termed *Internal Combustion Engine,* working on the principle of either the reciprocating engine or the turbine. While the external combustion engine, i.e., the steam engine, receives its working medium, the steam, ready made, and depends therefore on such auxiliaries as the boiler and furnace, the internal combustion engine has to produce its own working medium — hot high-tension gases, and moreover must do this in a fraction of a second. Hence the internal combustion engine fulfils the functions of the steam engine and the steam boiler with furnace combined, and is simpler than the latter; but it is just this simplicity which presents much more difficult and diverse problems in the design and construction of the internal combustion engine than in the steam engine. The ability of the internal combustion engine to utilize almost any kind of fuel and its broad field of application to stationary and automotive power generation have brought into use such easily

definable and special names as Illuminating Gas Engine, Producer Gas Engine, Blast Furnace Gas Engine, Coke Oven Gas Engine, Natural Gas Engine, Alcohol Engine, Gasoline Engine, Heavy Oil Engine, Automobile Engine, Truck Engine, Tractor Engine, Marine Engine, Aircraft Engine.



II. Fundamental Principles.— Whatever the fuel or the field of application may be, every internal combustion engine has to satisfy the following main requirements:

1. THE CYCLIC FUNCTIONS, i.e., the *Admission, Compression, Ignition* and *Combustion* of the *Charge* within a fixed space, called *Combustion Chamber,* thus producing *Expansive Power,* and finally the *Exhaust* of the *Burned Gases.*

2. THE TRANSMISSION OF THE POWER from the *Combustion Cylinder* to the *Shaft.*

3. THE CONTROL OF THE TEMPERATURE OF THE MECHANICAL ELEMENTS by means of *Cooling Devices.*

4. The Adaptation of the Power Supply of the Engine to the Load Demand upon the Engine by means of *Governing Methods.*

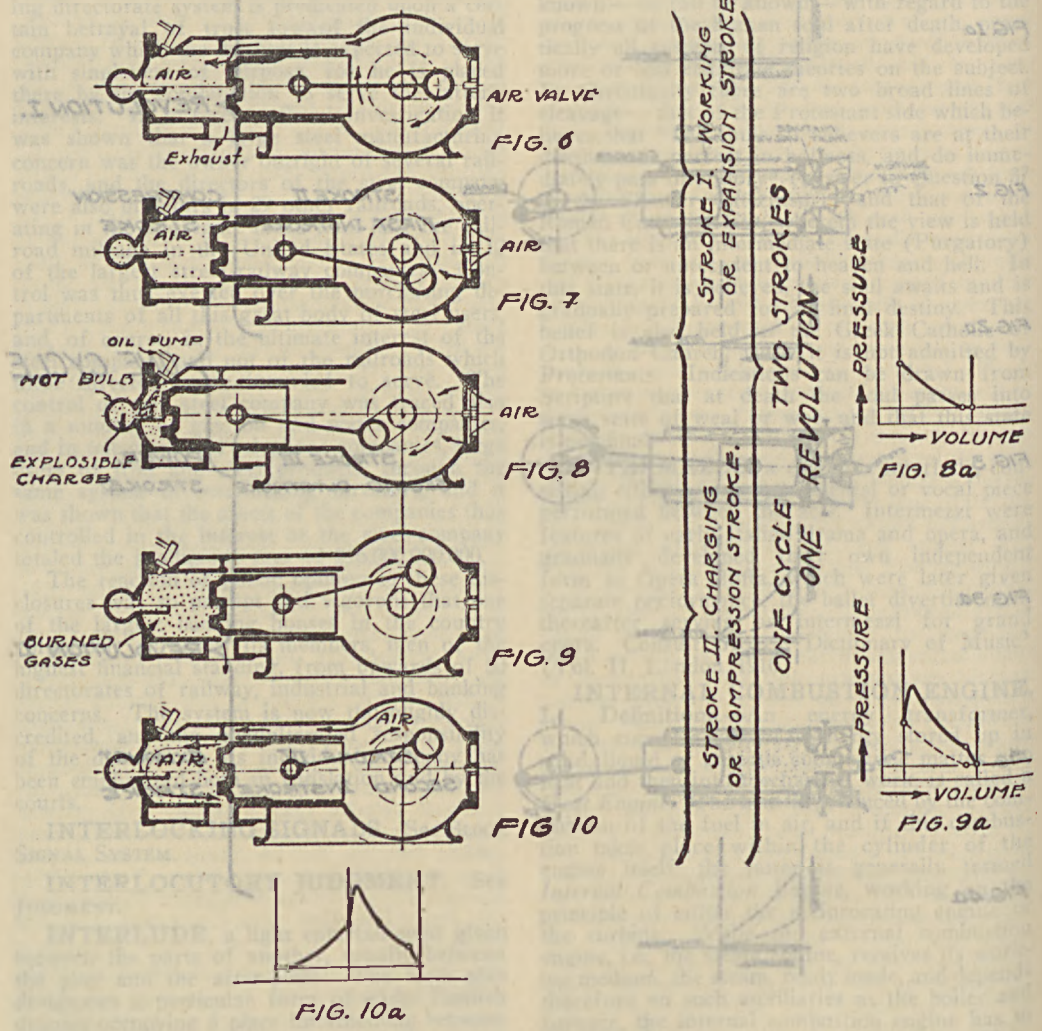
5. The Mixing of Fuel and Air by means of *Carburetors* and *Atomizers.*

These problems are of a chemico-physico-mechanical nature, and are intimately interwoven. Each of the requirements cannot, however, be realized to its highest degree. For instance, with regard to stress conditions, it is very desirable to keep the cooling medium at the lowest possible temperature; yet the lowest fuel consumption is attained only at a fairly high temperature of the cooling water. Thus in all practical cases there can be only an approximate solution, which must necessarily be a happy balance between contradicting conditions. Furthermore, the location of the engine as well as the kind of service causes still more difficulties, and indeed difficulties of a special nature. The problems of the air-craft engine, for instance, are decidedly different from those of the automobile engine, while the latter requires features of design which are seldom embodied in the stationary type of engine.

1. Cyclic Functions.—In order to satisfy the above five basic requirements, the internal combustion engine has to pass through a definite «Cycle of Operation»; that is, its piston has to make a number of single strokes to gain one «Power» or «Impulse» stroke, known as the «Working stroke.» To-day the *four-stroke cycle* and *two-stroke cycle* are most commonly used, and are briefly called four and two cycle, respectively.

(a) Four-Stroke Cycle.— In the diagrams, Figs. 1 to 4, a four-stroke cycle single acting gas engine is briefly illustrated.

Fig. 1 represents the engine with the piston on the suction stroke, or its first out-stroke. During this stroke a charge of gas and air, previously mixed in the mixing chamber, is taken in through the inlet valve. In Fig. 2 the piston is starting on its first in-stroke or compression stroke. The inlet valve is closed and the charge compressed. At or near the end of the stroke, ignition occurs. Fig. 3 shows the piston, just after the ignition of the gases, at the beginning of the working stroke, which is now the second out-stroke. Due to the combustion of the mixture within the cylinder, both the temperature and the pressure of the gases increase suddenly. The high-tension gases thus produced drive the piston out, and while doing this useful work gradually expand to nearly atmospheric pressure. At the end of this stroke the exhaust valve is opened and the inert gases are forced out of the cylinder during the fourth stroke, Fig. 4, known as the exhaust stroke, at or near the end of which the mixture inlet valve is opened, starting the cycle over again. The changes of pressure within the cylinder during the different strokes are represented in the pressure-stroke or pressure-volume diagrams, Figs. 1a, 2a, 3a, 4a; in Fig. 5 these pressure-volume diagrams are developed. During the first, second and fourth strokes the engine performs the functions of a pump, deriving its power from the excess energy stored up in the flywheel during the power stroke. The power is automatically adapted to the load demand by a governor acting on the gas inlet throttle value. During the cycle, a cooling medium, usually water, flows through the jacket surrounding the cylinder to carry away the heat transmitted through the cylinder walls, thus preventing overheating of the latter.



(b) Two-stroke Cycle.— To illustrate the two-stroke cycle principle, a two-stroke cycle single acting oil engine has been selected. See Figs. 6 to 10.

In Fig. 6 the piston is in its outer dead centre position. The ports for both the scavenging air and the exhaust are uncovered by the piston, while the air inlet valve in the crankcase is closed. The cylinder as well as the crankcase is filled with air at atmospheric pressure. The piston on its in-stroke (Fig. 7) slides over the air inlet port, cutting off the cylinder from the crankcase. This causes the pressure in the latter to fall below that of the atmosphere, thereby opening the automatic air inlet valve and admitting fresh air to the crankcase. Further sliding of the piston then cuts off the exhaust port from the cylinder and compression starts. Before the piston reaches the inner dead centre (Fig. 8) the fuel is sprayed into the combustion space, which in this case is the hot bulb, where it is vaporized, mixed with air and ignited near dead centre; the first operation in the two-stroke cycle — the compression stroke — is now completed. The temperature and the pressure of the gases within the cylinder increase quickly, and the high-tension gases, expanding gradually, force the piston out (Fig. 9), thus doing useful work. At a point where the piston has yet to travel about 15 per cent of its stroke, the exhaust port is uncovered by it and the exhaust gases are discharged. Further sliding uncovers the inlet port (Fig. 10), and the air in the crankcase, being compressed slightly above atmospheric pressure, rushes into the cylinder and sweeps out or scavenges the inert gases. This completes the cycle. Figs. 8a, 9a and 10a illustrate again the changes of pressure within the cylinder during the cyclic events. One further feature to be noted is the necessity of a fuel pump for the two-stroke cycle engine. During the compression stroke, the excess of energy which was stored up in the flywheel during the power stroke, is consumed. The power is adapted to the load by the action of the governor on the fuel pump. To assure continuous operation some heat is transmitted through the walls and carried away by the cooling medium passing through the water jacket.

(c) Four-Stroke versus Two-Stroke Cycle. — Even though the two-stroke cycle is theoretically superior to the four-stroke cycle, yet the latter predominates. We can very readily see by comparison why this is true. The main advantages of the four-stroke cycle are its simple construction, high speed and low cost for small engines; its disadvantages being the varying torsional moment, heavy flywheel, small specific output, large dimensions and contamination of the new charge by the burned gases. As to the main advantages of the two-stroke cycle, they are a specific output which is about 75 per cent to 90 per cent larger than in the four-stroke cycle; the size of the engine is about half of that of a four-stroke cycle engine for the same power output, hence it has lower weight; good scavenging with a correspondingly purer mixture and larger unit charge; elimination of valves by using slots or ports in cylinder walls, thus assuring a more reliable construction; more uniform torque; ease of reversibility; large overload capacity; ratio of cooling surface to displacement volume larger, hence better cooling effect and higher compression than in the four-stroke cycle. On the other hand, we have disadvantages which may be stated as follows: the charge must be moved through two cylinders, hence greater frictional resistance and lower mechanical efficiency; low speed; heat losses during the power stroke larger than in the four-stroke cycle. Quite recently, however, the two-stroke cycle has come into wider use, especially for high power units operating on crude oil as fuel. Among experts it is a doubtful question as to the superiority of the one over the other, the more so as the two-stroke cycle engine is not yet fully developed. Only the future can tell which of the two will be the final victor in the race for supremacy in design, construction, operation and economy.

(d) Constant Volume and Constant Pressure Cycle.— In both the four-stroke and two-stroke cycle engines, ignition with consequent combustion of the charge, or the introduction of heat into the cycle, may take place either at approximately constant volume with pressure increasing rapidly (Fig. 11), or at approximately

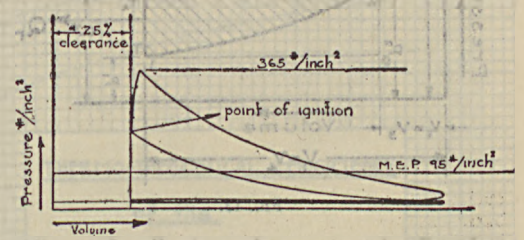


FIG. 11.— Average Pressure-volume diagram of Otto Engine at Full Load.

constant pressure with volume increasing gradually (Fig. 12). In the first case the engine is usually spoken of as an «Explosion» or «Otto» engine, while the constant pressure engine is usually called a «Combustion» or «Diesel» engine. The late August N. Otto of

Cologne, and the late Rudolph Diesel of Munich were the first successful builders of the constant volume and constant pressure engines, respectively.

There have been many other cycles invented and more or less successfully applied (see *Historical Development*), yet the fact remains that almost all internal combustion engines in practical operation to-day are running either on the Otto cycle or on the Diesel cycle, the former being the older and considerably in the lead.

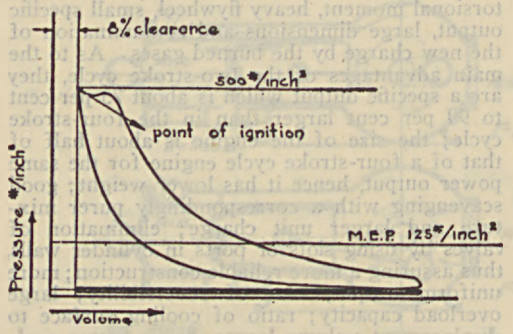

FIG. 12.—Average Pressure-Volume Diagram of Four-stroke Cycle Diesel Engine at Full Load.

In comparing these two cycles as to theoretical thermal efficiency, it is assumed that: (1) the gas used follows the law of a perfect gas; (2) the ratio of the specific heats «κ» is constant; (3) the cylinder in which the cycle takes place is absolutely heat tight, i.e., adiabatic heat conditions exist; (4) the inlet and outlet valves open and close exactly at dead centre; (5) the work consumed during the suction and the exhaust strokes is neglected.

Otto Cycle.— Referring to Fig. 13, we can follow through the different operations of the

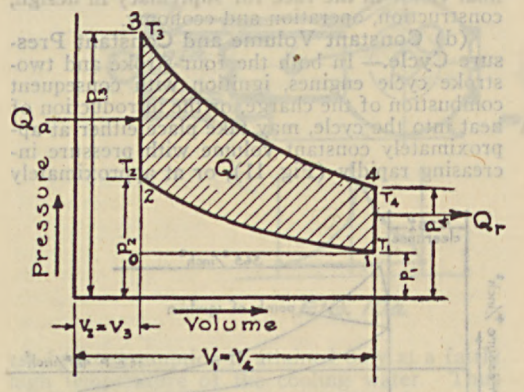

FIG. 13.

cycle. Suction occurs along the line 0–1; adiabatic compression along 1–2; ignition and combustion at constant volume and addition of heat, Q_a, along the line 2–3, with a resulting increase of the absolute temperature T_2 to T_3 and pressure p_2 to p_3; adiabatic expansion along 3–4; and exhaust along 4–1–0, whereby heat, Q_r, is rejected along 4–1. This completes the cycle and the heat $Q = Q_a - Q_r$ has been transformed into work represented by the area 1–2–3–4–1. As the efficiency is the ratio of the output over the input we can write the expression:

1) $\eta_t = \frac{Q}{Q_a} = \frac{Q_a - Q_r}{Q_a}$

$$\eta_t = 1 - \frac{Q_r}{Q_a}$$

According to the laws of thermodynamics,

2) $Q_a = Wc_v(T_3 - T_2)$ = heat added;

3) $Q_r = Wc_v(T_4 - T_1)$ = heat rejected;

where W is the weight of the charge and c_v the specific heat at constant volume. Then, since

4) $\frac{T_3}{T_2} = \frac{T_4}{T_1}$, and for adiabatic curves

5) $\frac{T_2}{T_3} = \left(\frac{V_3}{V_2}\right)^{k-1} = \frac{P_2}{P_3}$ equation 1 assumes the form

1a) $\eta_t = 1 - \frac{1}{r^{k-1}}$ = theoretical thermal efficiency

of the Otto cycle, «r» being the ratio of compression, $\frac{V_1}{V_2}$. Thus the thermal efficiency of the Otto cycle increases with the compression ratio «r», as well as with the ratio of specific heats «κ». Since the latter is a function of the mixture ratio of gas to air, the efficiency depends also on the mixture ratio. Lean mixtures give higher values of κ and better efficiencies than rich ones. For instance, for $\frac{V_1}{V_2} = r = 2$ and $\kappa = 1.2$, $\eta_t \cong 13$ per cent while for $\frac{V_1}{V_2} = r = 10$, $\eta_t \cong 60$ per cent.

Diesel Cycle.—As in the Otto cycle, we can determine the thermal efficiency from the theoretical card. Referring to Fig. 14, suction takes place along 0—1; adiabatic high compression of the air along 1–2; spraying of fuel into the cylinder by means of highly compressed air, self-ignition and combustion along 2–3, thus adding the heat, Q_a, to the cycle; adiabatic expansion along 3–4; exhaust along 4–1–0 whereby heat Q_r is rejected. The cycle is thus completed, the heat $Q = Q_a - Q_r$, being transformed into work represented by the area 1–2–3–4–1. Using the same notation as above, we have,

6) $\eta_t = \frac{Q}{Q_a} = \frac{Q_a - Q_r}{Q_a} = 1 - \frac{Q_r}{Q_a}$

7) $Q_a = Wc_p(T_3 - T_2)$ = heat added;

8) $Q_r = Wc_v(T_4 - T_1)$ = heat rejected:

9) $\frac{T_3}{T_2} = \frac{V_3}{V_2} = L$

«L» being the ratio of the loads or ratio of cut-off volume to compression volume.

10) $\frac{T_4}{T_1} = \left(\frac{V_3}{V_2}\right)^{\kappa} = L^{\kappa}$

Equation 6 takes the form

6a) $\eta_t = 1 - \frac{1}{r^{\kappa-1}} \times \frac{1}{\kappa} \times \frac{L^{\kappa} - 1}{L - 1}$,

giving the theoretical thermal efficiency of the Diesel cycle. The thermal efficiency of the Diesel cycle thus depends not only on the ratio of compression r, and the ratio of specific heats κ, but also on the ratio of the loads L.

For instance,

for $r = 13$, $\kappa = 1.41$, $L = 1.5$, we get $\eta_t =$ 61.5 per cent

and for $r = 13$, $\kappa = 1.41$, $L = 3$; $\eta_t = 54$ per cent.

This shows that the thermal efficiency of the Diesel cycle decreases with the increase of the ratio of loads.

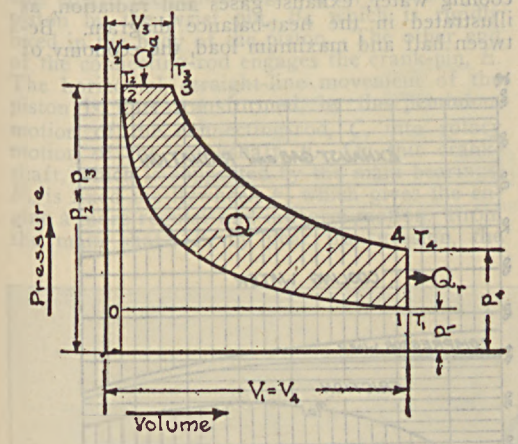

FIG. 14.

In Fig. 15, the efficiencies of the Otto as well as of the Diesel cycle are graphically represented for equal ratios of compression, r, heats, κ, and loads, L. From these diagrams it is evident that at equal compression ratios, the Otto cycle is superior to the Diesel. In practice, however, the Otto cycle is limited in regard to the compression ratio ($r = 8$), in order to prevent pre-ignition, while the Diesel engine must essentially use a high compression, r being in this case approximately 16. At a low ratio of load, $L = 1.5$, the Diesel engine has the higher efficiency. At full load however, L being approximately 3, the thermal efficiency of both cycles is about the same, in which case their maximum combustion pressures, p_3, are about the same.

2. Transmission of Power from Cylinder to Shaft. (A) *Indicated Efficiency. Indicated Horse Power.*— The thermal efficiency as computed above can never be realized in practice since many factors upon which it depends cannot be mathematically considered. Thus the assumption that compression and expansion curves are adiabatic in character is not true. There must be heat losses due to cooling, radiation, incomplete combustion and several other reasons. The degree of variation of the specific heats with a change in temperature or pressure or both is still an open question. The combustion lines are never true constant-volume or constant-pressure lines. Fig. 16 shows

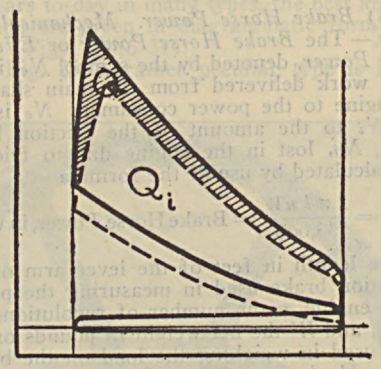

FIG. 16.

the theoretical diagram representing the heat Q, and the actual diagram representing the indicated heat, Q_i, actually converted into work. The difference of the two areas gives the actual loss due to the factors cited above. The ratio $\frac{Q_i}{Q}$ has a value from .5 to .8 and is sometimes called the card factor.

The theoretical efficiency, η_t, is thus reduced to: $(\eta_t \frac{Q_i}{Q}) = \eta_i$ the Indicated Efficiency.

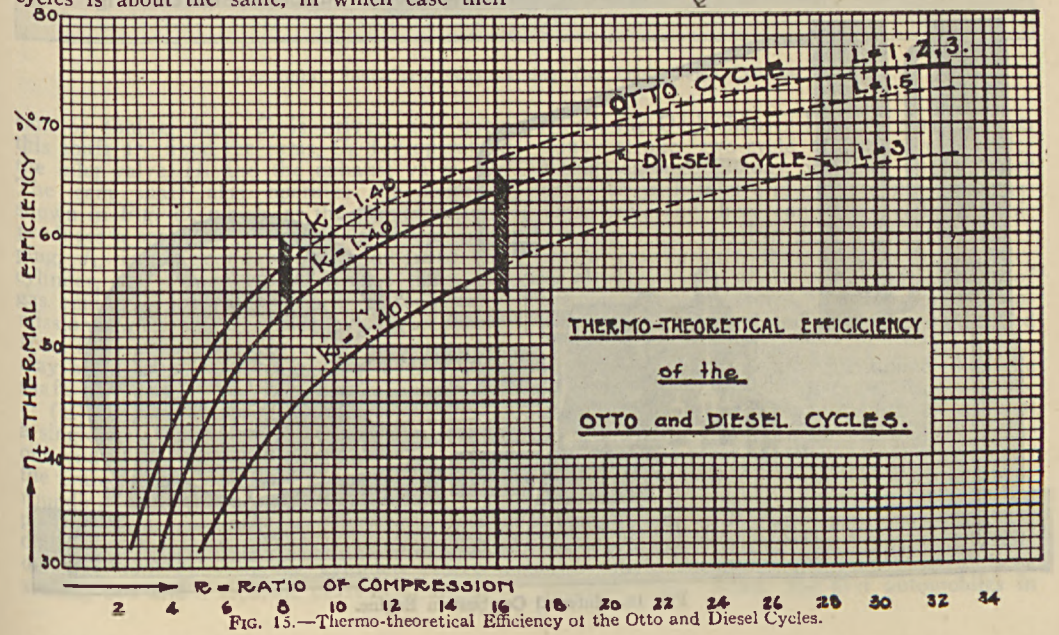

FIG. 15.—Thermo-theoretical Efficiency of the Otto and Diesel Cycles.

The *Indicated Horse Power*, denoted by the symbol N_i, is the work actually developed within the cylinder.

It is in direct proportion to the area of the pressure-volume or indicator diagram as actually obtained by means of an indicator, and can be computed by means of the formula

$$N_i = \frac{p_i\ S\ A\ X}{33{,}000} = \text{indicated horse power,}$$

in which p_i is the mean indicated pressure from the indicator diagram in pounds per square inch, S the length of the engine stroke in feet, A the net area of the piston in square inches, X = the number of power strokes per minute, and 33,000 the number of foot-pounds per minute in one horse power.

(B) *Brake Horse Power. Mechanical Efficiency.*— The *Brake Horse Power* or *Effective Horse Power*, denoted by the symbol N_e, is the actual work delivered from the main shaft of the engine to the power consumer. N_e is less than N_i to the amount of the friction horse power, N_f, lost in the engine due to friction. It is calculated by use of the formula

$$N_e = \frac{2\pi l n W}{33{,}000} = \text{Brake Horse Power, in which}$$

l is the length in feet of the lever arm of the absorption brake used in measuring the power of the engine, n the number of revolutions per minute, and W the net weight in pounds on the scales used in weighing the load on the brake.

The *Mechanical Efficiency*, η_m, is the ratio of the brake horse-power, and is expressed as $\eta_m = \frac{N_e}{N_i}$. Test results show an increase in η_m with an increase of the ratio of loads, but a decrease of η_m with an increase of the ratio of compression if p_i does not change materially.

(C) *Over-all Efficiency.*— The product of $\eta_i \times \eta_m \times \eta_w$ = *Over-all Efficiency*, commonly called "Brake Efficiency" or "Economical Efficiency." It furnishes the means by which the value of any internal combustion engine with regard to fuel economy may be measured.

This economical efficiency, η_w, varies with the load of the engine, as shown in Fig. 17, which is the *heat-balance diagram* of a 15 HPe (effective) Diesel Oil Engine. At normal output, 15 H.P. of the engine, 30 per cent of the available heat is converted into useful work, while the remainder is lost in friction, cooling water, exhaust gases and radiation, as illustrated in the heat-balance diagram. Between half and maximum load, the economy of the Diesel Oil Engine varies only slightly, in which respect it is superior to the Otto engine which shows a more rapid decrease in economy.

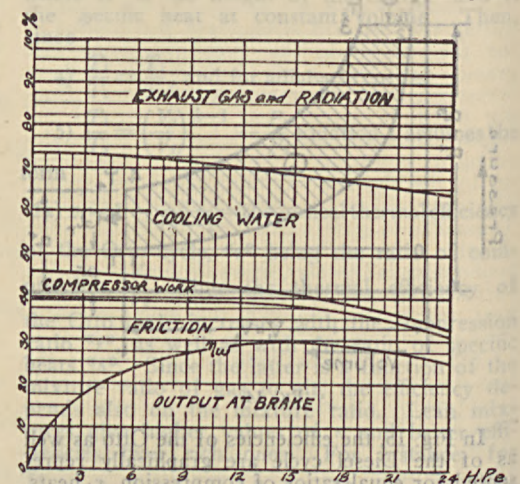

FIG. 17.—Heat Balance Diagram of 15 H.P. Diesel Motor.

(D) *Essential Mechanical Elements.*— The power developed within the cylinder may be transmitted to the rotating shaft either according to the turbine or the reciprocating engine principle. As, to-day, gas turbine power is not in practical use for internal combustion engines, the latter only will be considered. Fig. 18 illustrates the mechanical elements of a single-acting, horizontal gas engine.

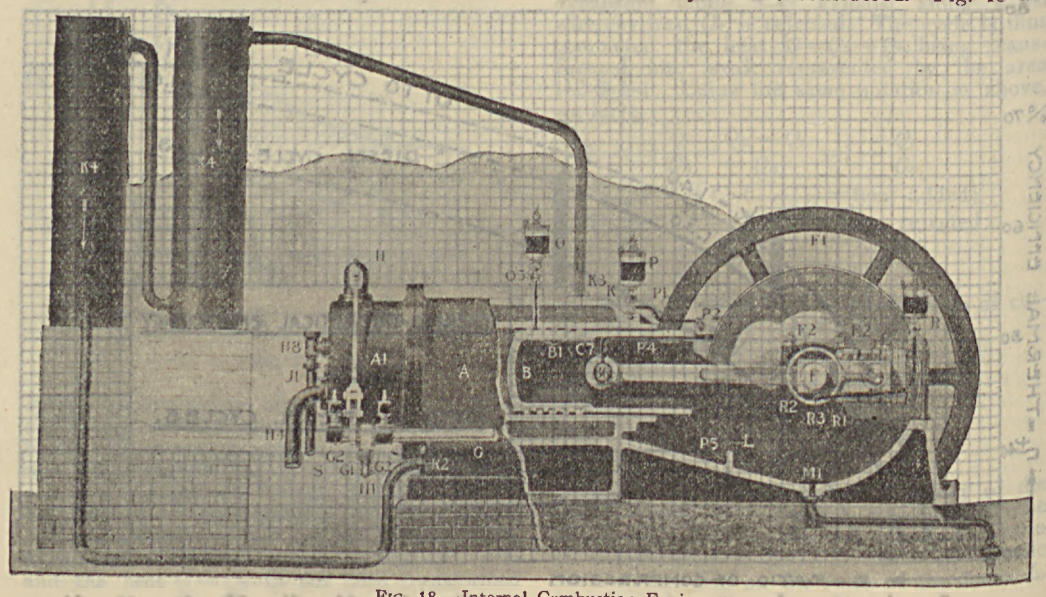

FIG. 18.—Internal Combustion Engine.

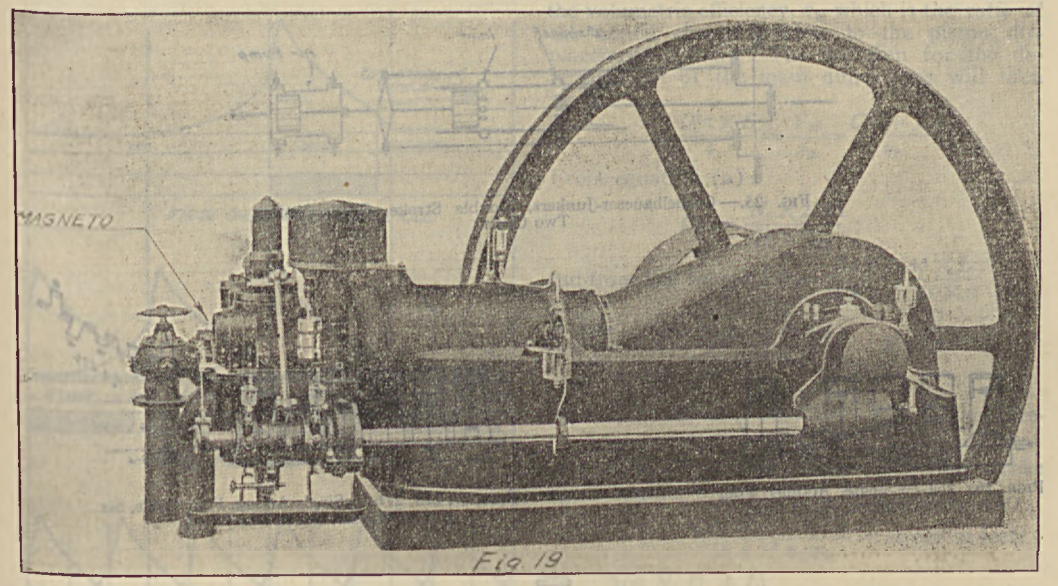
In the cylinder, A, is a close-fitting trunk piston, B, a long open-ended piston, fitted with piston rings, B_1, held in position in their grooves and prevented from revolving by means of small pins, placed at different position for each ring, so that the joints of the rings cannot work in line and allow the gases to blow past them. One end of the connecting-rod, C_1, is held to the piston by the wrist pin, B_6, which is rigidly fixed in the body of the piston. The other end of the connecting-rod engages the crank-pin, E. The horizontal, straight-line movement of the piston is thus transformed, by the pendulum motion of the connecting-rod, C, into rotary motion of the crankshaft, F. On this crankshaft, which is supported by the main bearings, F_2, is fixed the flywheel, F, which gives the engine a more regular and uniform motion. From the main shaft, F, by gear transmission, the cam or timing shaft, G, is driven, and upon this shaft are fixed the cams, G_1, for operating the inlet valve, H, and the exhaust valve, H_1. The cam shaft also operates the magneto shown in Fig. 19, which, at the proper instant, produces a spark at the terminals of the spark plug, J_1, in the combustion chamber of the cylinder, A. Power is distributed from the gas engine to the shafting belt or rope transmission from the flywheel, by geared drive from the main shaft, or by an electric generator may be mounted on an extension of the main shaft.



Horizontal, Four-Cycle, Single-Acting, Gas Engine, One Cylinder.

(E) *Single- and Double-Acting Engines.*—In a single-acting engine, Fig. 20, work is done at one end of the cylinder only, while the other, the crank end, is open and exposed to the surrounding air, thus giving a cooling effect. The piston usually serves as a cross-head. In a double-acting engine, Figs. 23 and 24, work is done at both ends of the cylinder. Here a stuffing box and a separate cross-head are necessary and the piston and its rod must be cooled. All modern small and medium-sized engines are of the single-acting type. Only in such cases where the highest possible cylinder capacity is required do manufacturers attempt to produce the double-acting engine. At the present time, the record capacity per cylinder of the double-acting two-cycle type is about 2,000 horse power; of the four-cycle, about 1,500 horse power.

(F) *Multi-Cylinder Arrangements.*— In the course of its development and branching out into the various fields of application, the internal combustion engine has been subjected to so many requirements and influenced by such factors as space, weight, uniformity of rotation, economy, reliability and flexibility, that it appears to-day in many types, the best known of which are given in diagrammatic form following (Figs. 20 to 31).

In Fig. 25, a rather peculiar type is illustrated, the Oechelhäuser-Junkers, single-acting, double-stroke, two-cycle engine. Two single-acting, opposed pistons, work in one cylinder provided with inlet and outlet slots. A transverse yoke and three connecting rods transmit the power developed in the cylinder to a three-throw crank shaft, thus freeing the cylinder of all stresses but those to the radial action of the combustion pressures. Furthermore, the engine is well balanced and therefore well suited for marine purposes.

It must be especially mentioned that the vertical, single-acting four-cycle, four and six cylinder, all in line, Figs. 26 and 27, as well as the eight cylinder, Fig. 31, and 12 cylinder, Fig. 35, V-type, the latter occasionally called the twin six, have become the most popular engine types in automobile, marine and aircraft practice. The reason for it is that these types give a more equal flow of power and weigh less per unit power than the one cylinder type. When the first automobiles in

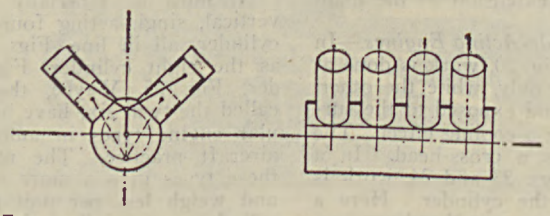

FIG. 31.— Single Acting, Four Cycle, Eight Cylinder, V-type.

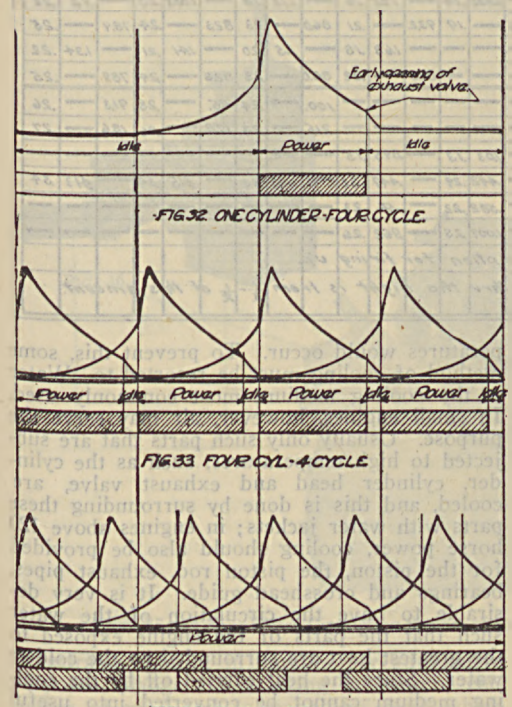
America were made, the gasoline engine used for propelling it was of the one cylinder, four cycle, horizontal, slow speed type, Fig. 20. The heavy vibrations due to the irregular torque caused discomfort to the passengers and damage to the vital parts of the engine and vehicle. To avoid this, automobile designers have gradually adopted the vertical, high-speed, multi-cylinder type, in which the power is obtained by high rotative speed rather than by large bore and stroke. To illustrate this, in Figs. 32, 33 and 34 the pressure-volume curves have been drawn for four-stroke cycle engines of one, four and six cylinders, respectively. From these curves it is evident that in the one cylinder type the power impulse is followed by a long idle period; in the four cylinder engine a small gap only remains, due to the early opening of the exhaust valve, while in the six cylinder type the torque curves overlap, thus causing a continuous flow of power with no periods of



idling. This factor is a requisite in the operation of airplanes and very desirable in automobiles, since flexibility and performance of the motor is appreciated by any driver, especially in heavy traffic.

(G) *Main Dimensions of Internal Combustion Engines.*—Among the many methods of computing the main dimensions of the internal combustion engine, not one is wholly reliable or exact. The one giving the best practical results is that of a German authority, Hugo Gueldner. It is based on the practical amount of air, *Lh*, required in one hour, if the fuel consumption per hour is *Ch*, both *Lh* and *Ch* being in cubic feet for gaseous, and in pounds for liquid fuel. Using the former equation,

$$\eta_w = \eta_i \times \eta_m, \text{ we have}$$

$$\eta_w = \frac{N_e\ 33{,}000 \times 60}{Q\ 778}$$

$$\eta_w = \frac{N_e 2545}{C_h H}, \qquad \ldots\ldots (a)$$

where H is the lower heat value in British Thermal Units of the fuel consumed. Considering that the actual charge volume drawn in during one suction stroke consists of the fuel, $C_{st} = \frac{C_h}{30 \times n}$ and a corresponding amount of air, $L_{st} = \frac{C_h \times L}{30 \times n}$, the sum of the two, V_{st}, is equal to the piston displacement, $\frac{D^2\pi}{4} \times S$, times the volumetric efficiency, η_v, which is the ratio of the actual charge volume to the piston displacement volume. The equation for the determination of the main dimensions will then be

$$\frac{D^2\pi \times S}{4} = \frac{V_{st}}{\eta_v} = \frac{C_{st} + L_{st}}{\eta_v}.$$

From equation (a):

$$C_h = \frac{N_e \times 2545}{H \times \eta_w};$$

and from this we get $Lst = \frac{N_e \times 2545 \times L}{H \times \eta_w \times 30 \times n}$

or $\frac{D^2\pi}{4} \times S = \frac{84.8\ N_e\ (1+L)}{n \times H \times \eta_i \times \eta_w}$. Hence:

(b) . . . . $D = \sqrt{\frac{108\ N_e\ (1+L)}{S\ n\ H\ \eta_v\ \eta_w}}$ = the effective diameter of the cylinder for a four stroke cycle engine, measured in feet, and

$$S = \frac{108\ N_e\ (1+L)}{D^2\ n\ H\ \eta_i\ \eta_w} = \text{stroke in feet;}$$

$$n = \frac{108\ N_e\ (1+L)}{D_2\ S\ H\ \eta_v\ \eta_w} = \text{number of revolutions}$$

per minute. For two cycle engines, it is obvious that the factor 54 would be used instead of 108. In the above equations L is the air in cubic feet actually used to burn one cubic foot of the gaseous, or one pound of the liquid fuel, while N_e is the effective horse power for one cylinder end only. In view of the amount of experimental data available, a selection of L, H and η_w can easily be made. For this purpose the tables 1 and 2 are inserted.

TABLE No. 1. VOLUMETRIC EFFICIENCY.

from .93 to .88 for slow speed engines, mechanically operated inlet valve;
from .87 to .80 for slow speed engines, automatically operated inlet valve;
from .85 to .80 for high speed engines, mechanically operated inlet valve;
from .75 to .65 for high speed engines, automatically operated inlet valve;
from .65 to .50 for extremely high speed engines, automobiles and air-craft engines.

* Including 10 15% of the full daily fuel consumption for firing up. The consumption of a gas-producer banked thru the night is from 1/3 - 1/2 of this amount.															

Example.—A four-cycle, single-acting, one-cylinder anthracite producer gas engine is to develop 170 horse power, at a piston speed of 800 feet per minute and a stroke-diameter ratio $\frac{S}{D} = 1.35$. What are its main dimensions?

Solution.— From Table No. 1 use $\eta_v = .90$;
From Table No. 2 use $\eta_w = .26$;
$H = 140$ B. T. U.
$L = 1.5$ cube feet.

And since $n = \frac{C}{2S} = \frac{800}{2.7D} =$ Revolutions per minutes.

These values substituted in equations (b) and solving for $D = \sqrt{\frac{108 \times N_e (1+L)}{S \times n \times H \times \eta_w \times \eta_v}} =$

$$\sqrt{\frac{108 \times 170(1+1.5) \times 2.7}{1.35 \times 800 \times 140 \times .26 \times .9}} =$$

1.877 feet = 22.5 inches.

$S = 1.35 \times 22.5 = 30$ inches.

$n = \frac{800}{2 \times 30} = 166$ Revolutions per minute.

3. Cooling.— The maximum temperature developed within the cylinder of internal combustion engines is 2,500° F., or more. It is evident that neither cast iron and cast steel nor any other metal known at the present time could resist such high temperatures. Furthermore, pre-ignition of the charge and distortion of the elements exposed to such high temperatures would occur. To prevent this, some method of cooling must be resorted to. Water is the cooling medium most commonly used. In small engines, however, air may serve the purpose. Usually only such parts that are subjected to high temperatures, such as the cylinder, cylinder head and exhaust valve, are cooled, and this is done by surrounding these parts with water jackets; in engines above 120 horse power, cooling should also be provided for the piston, the piston rod, exhaust pipes, bearings and crosshead guide. It is very desirable to have the circulation of the water such that the parts of the engine exposed to the greatest heat are surrounded by the coldest water. Since the heat carried off by the cooling medium cannot be converted into useful work, it is evident that there must be a certain loss due to this cooling of the engine. The amount of this loss, see Fig. 17, depends on many factors, such as type and load of engine, size of cylinder, temperature of cooling water, and so on, and varies from 25 per cent to 50 per cent of the heat developed within the cylinder. However, there is danger from over-cooling as well as from under-cooling. If the engine is over-cooled, the clearance between the piston and cylinder is decreased, the lubricating oil gets more sluggish, and there will be a large increase in mechanical friction, with a corresponding decrease in mechanical efficiency. On the other hand, if the engine is not sufficiently cooled, there is danger from pre-ignition, excessive expansion of parts, and at very high temperatures, actual failing of the cylinder and piston.

Each of the cooling systems has its advantages and disadvantages. The main advantages of air cooling are simplicity, light weight, no charge for the cooling medium, and no danger of cracking the cylinder by freezing; the disadvantages which may be cited are applicability to small engines only, no positive control over the temperature, burning of the cylinder lubricating oil, and in most cases high fuel consumption. In the standard method of water cooling, we have such advantages as the control of the temperature regardless of weather conditions, the possibility of cooling internal parts of large engines and the regulation of the clearance space between the cylinder and piston, which in turn means the partial control of the piston friction and also the prevention of the escape of gases into the engine room. On the other hand, there are certain disadvantages of the water-cooled engine. There is an increase in weight which is a most

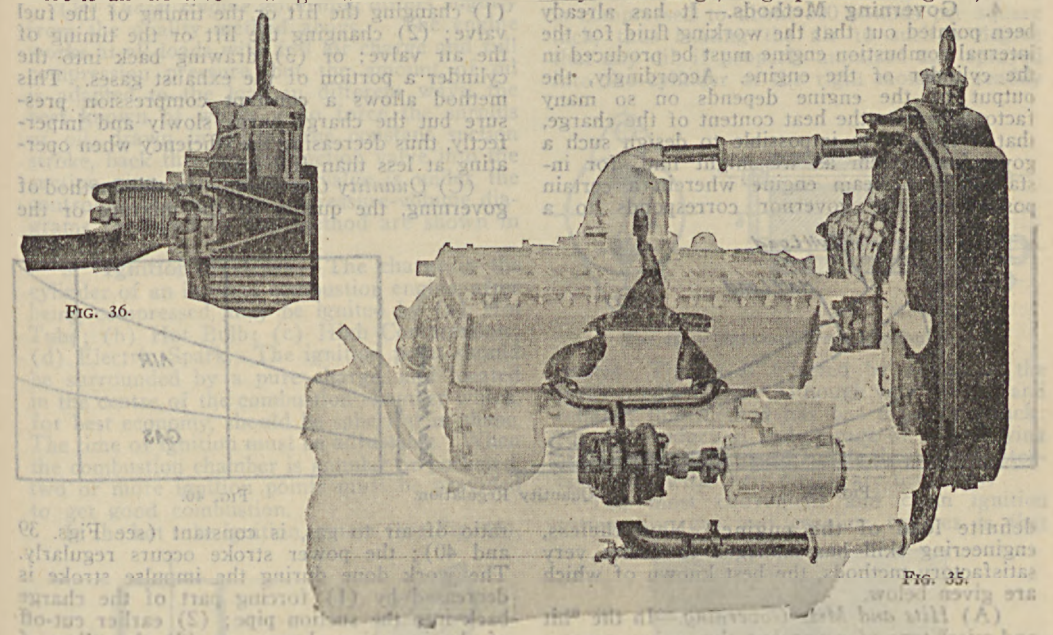

FIG. 36.

FIG. 35.

FIGS. 35 and 36.—Water Circulating System of Packard 12 Cylinder "V" Type Automobile Engine.

undesirable feature in engines for automotive purposes; danger of freezing in winter; collection of mud and formation of scale which will clog up the water passages; and the failure of the feed pump where forced circulation is used.

In automobiles, trucks, tractors and airplanes, it is necessary to reclaim the water. In this case the water is circulated through a so-called radiator, Fig. 35.

This consists either of a great number of round tubes with fins to radiate the heat, or flat tubes through which the water flows in thin sheets. In addition, air is forced against these tubes by the forward movement of the vehicle and by a fan. The water, forced by means of a small pump into the jacket of the cylinder, gradually becomes warmer while passing upward, and finally is discharged into the top of the radiator. There it is divided into thin streams and directed against comparatively cold metal which abstracts heat from the water. Gradually cooling off, it flows down through the radiator to the suction pipe of the pump (illustrated in Fig. 35), which again forces it back into the jacket. A thermostat may be added (see Fig. 36), and the flow of the water so regulated that the temperature of the water is constant at all speeds of the engine. Some manufacturers do not use a pump at all, but resort to the natural method of water circulation — the thermo-syphon system — which, however, requires a larger amount of water and space.

Small and medium sized stationary engines are provided with a large water tank (see Fig. 18); the top of the tank is connected with the top of the water jacket, and the bottom of the tank with the bottom of the jacket. In small farm engines, this tank is an integral part of the cylinder jacket, thus eliminating piping entirely. In large, high-powered engines, the quantity of cooling water generally varies from 30 to 70 pounds per horse-power hour, depending upon the type and fuel used. A 6,000 horse-power engine would therefore require about 420,000 pounds of water per hour. Where such a quantity of clean water cannot be secured at a very low cost, the cooling water must be reclaimed. In the simplest design, the hot water is piped to a cooling pond where the heat is dissipated by radiation and evaporation. In such plants where ground area is limited, the pond is generally displaced by a cooling tower.

For all cases cited above, the cooling water must be clean, for if impurities settle in the water jacket, the cooling, especially of the cylinder walls, becomes defective, the temperature rises, and pre-ignition, caused by incandescent deposits of carbon within the combustion chamber, is likely to occur. Again, the film of lubricating oil between the piston, piston rings and cylinder walls is rendered so thin

that it loses its sealing power; the exploding gases then blow past the piston rings and the oil is burned and charred, thus destroying its lubricating value. Heavy wear, loss of power and even "freezing" of the parts are the inevitable results.

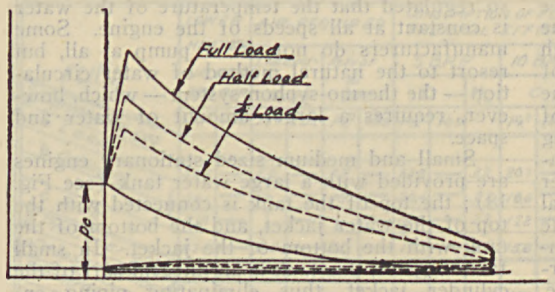

FIG. 37. Quality Regulation.

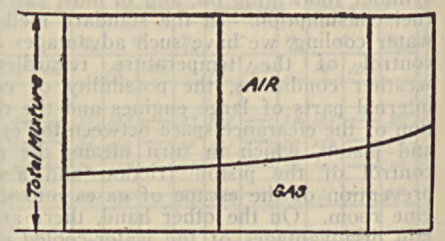

FIG. 38.

4. Governing Methods.—It has already been pointed out that the working fluid for the internal combustion engine must be produced in the cylinder of the engine. Accordingly, the output of the engine depends on so many factors, besides the heat content of the charge, that it is next to impossible to design such a governing system as we might find, for instance, in a steam engine wherein a certain position of the governor corresponds to a definite load of the engine. Nevertheless, engineering skill has managed to devise very satisfactory methods, the best known of which are given below.

(A) *Hits and Miss Governing.*—In the "hit and miss" type of governing, the engine operates under a constant quality and constant quantity charge. Explosions are cut out at irregular intervals by keeping either the gas inlet valve closed or the outlet valve open. Although the method is to be noted for its economy and simplicity, it is used only in small and medium sized engines and in such cases where an irregular speed of rotation is permissible.

(B) *Quality Governing.*—The quantity of the charge in this method is constant (see Figs. 37 and 38), and the power stroke occurs regularly; but here the impulse is diminished by lowering the quality of the charge or the mixture ratio of fuel to air. This is effected by (1) changing the lift or the timing of the fuel valve; (2) changing the lift or the timing of the air valve; or (3) drawing back into the cylinder a portion of the exhaust gases. This method allows a constant compression pressure but the charge burns slowly and imperfectly, thus decreasing the efficiency when operating at less than full load.

(C) *Quantity Governing.*—In this method of governing, the quality of the mixture or the ratio of air to gas, is constant (see Figs. 39 and 40); the power stroke occurs regularly. The work done during the impulse stroke is decreased by (1) forcing part of the charge back into the suction pipe; (2) earlier cut-off of the incoming charge; or (3) throttling of the charge during the suction stroke. Although in this system the compression pressure, and consequently the efficiency drop (see Fig. 40), the mechanical efficiency increases with the decrease of the output. In practice, quantity governing proves to be superior to quality governing.

(D) *Combination Quality—Quantity Governing* (illustrated in Figs. 41 and 42), is

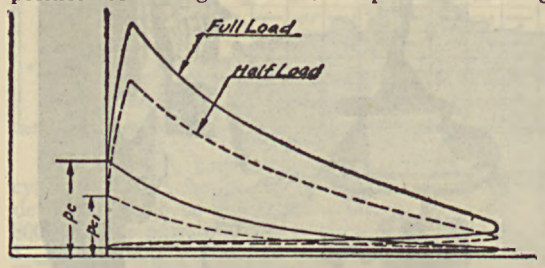

FIG. 39. Quantity Regulation.

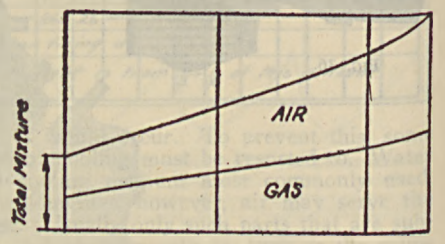

FIG. 40.

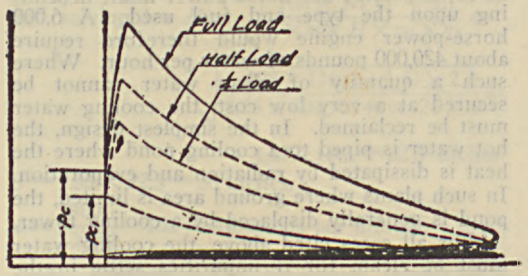

FIG. 41. Quality-Quantity Regulation.

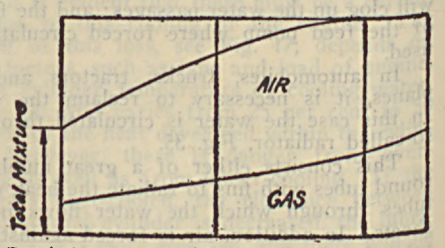

FIG. 42.

effected by using between maximum and half the load, the quality, and below half the load, the quantity method, thus combining the good features of these two methods.

(E) *Automotive Engines,* if running on light oil, such as gasoline, are generally governed by throttling the charge, and varying the time of ignition.

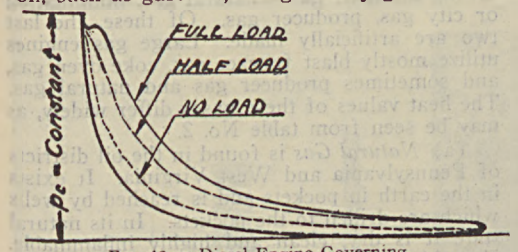

FIG. 43.— Diesel Engine Governing.

(F) *Diesel Engine* governing differs slightly from the quality method above. The engine works at all loads with full air charge and full compression pressure, but the amount of oil is adapted to the load in different ways, the best known of which is to force the surplus of oil, drawn in during the constant suction stroke, back through the suction valve into the suction pipe. The suction valve is under the control of the governor. Pressure-volume diagrams regulated by this method are shown in Fig. 43.

5. Ignition Systems.—The charge in the cylinder of an internal combustion engine, after being compressed, may be ignited by (a) Hot Tube; (b) Hot Bulb; (c) High Compression; (d) Electric Spark. The ignition point should be surrounded by a pure charge, and located in the centre of the combustion chamber which, for best economy, should be spherical in shape. The time of ignition must be adjustable. When the combustion chamber is annular or pocketed, two or more ignition points must be provided to get good combustion.

In the hot tube ignition system (see Fig. 44), a small tube of nickel, platinum or porcelain about three inches long and about one-quarter inch bore is fixed to the combustion chamber; the tube is heated by an external heat source. During the compression stroke, the charge is forced gradually into the tube, and as soon as it reaches the glowing zone, ignition occurs. Timing is effected by shifting the external heat well. This method is very simple and effective, but its short life and external flame carrier soon caused it to be displaced by fuller ignition systems.

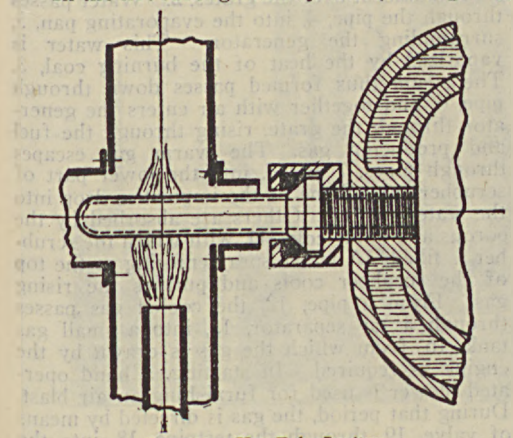

FIG. 44.— Hot-Tube Ignitor.

In the hot bulb system (see Fig. 8), a spherical or oval-shaped cast iron bulb serving as combustion chamber is fixed to the cylinder. It is heated by an external flame only for starting, and as long as the engine is cold. This method is very successfully used in oil engines. The fuel is sprayed into the bulb during the suction stroke in four stroke cycle engines, and during the compression stroke in two stroke cycle engines. There it is vaporized and then ignited by the compression temperature. In most cases timing is controlled by spraying water, in proper quantities, into the bulb.

In the high compression system of ignition such as we find in the Diesel engine, pure air is compressed to about 500 pounds per square inch, thus heating the air to such a degree that any oil, if properly atomized and sprayed into the cylinder at the right moment, readily ignites. Timing is effected by adjusting the spray-needle valve. Although very efficient and reliable, this method has one main drawback: for the production and storage of the spraying air, an air-compressor and high pressure storage tanks with their piping are necessary.

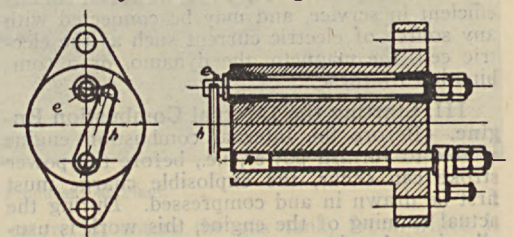

FIG. 45.— Make-and-Break Ignition Plug.

The most convenient and clean ignition system for gas and gasoline engines is that using the electric spark. Of this system there are two types: the low tension or break contact type (see Fig. 45) and the high tension or jump spark system (see Fig. 46). The former

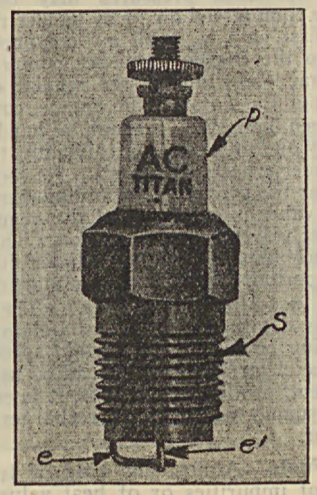

FIG. 46.— Spark Plug.

involves the motion of a rocker-shaft, *n*, with a contact hammer *h*, acting on a stationary electrode, *e*. The two parts coming together are necessarily subject to wear, which thus prevents the formation or deposit of carbon on the contact faces; in this way the gases have free access to the spark at the moment of break of contact and this system is well suited for large low speed engines where a hot, "fat," spark is most desirable.

The jump spark igniter (Fig. 46), called the spark plug, has no moving parts. It consists of a shell, *s*, containing *e*, one of the electrodes, screwed into the combustion chamber wall, and a porcelain insulator, *p*, carrying in its centre the second electrode, *ē*. The two electrodes must have a proper gap, about one-thirty-second inch, and be soot proof. To jump this gap, the electric current must have a high pressure, about 10,000 volts, produced by a secondary or induction coil, and a breaking device in the primary coil. Thus the jump spark has electrical complication and mechanical simplicity, while the break spark has mechanical complication and electrical simplicity. They are, however, equally efficient in service, and may be connected with any source of electric current such as the electric cell, the magneto, the dynamo, or a combination of these.

III. Starting the Internal Combustion Engine.— Before the internal combustion engine is able to furnish power, i.e., before the power stroke can occur, the explosible charge must first be drawn in and compressed. During the actual running of the engine, this work is usually done by the energy stored up in the flywheel; with the engine at rest, however, no energy is available from the wheel. Hence, to start the engine, an external power source is necessary. Small engines working with low compression pressure may be started by hand. Nothing more than a hand crank is used for this. It is attached directly to the crankshaft. High-powered engines and those working on high compression pressures may be started either by compressed air or by an electric motor. In the first case, a small air compressor connected to the engine furnishes compressed air to a storage tank during the regular operation of the engine. To start the engine, compressed air is then admitted, through a hand or mechanically operated starting valve, into the working cylinder where it expands. As soon as the engine has the proper speed and momentum, the starting valve is cut out and the regular inlet and outlet valves set in operation. There must be no fuel admitted to the cylinder during the starting period. Electric motor starting is extensively used in automobiles. The electric current is drawn from an accumulator during the starting period. At a certain speed of the engine the electric motor, instead of using electric current, produces it, that is, it is converted into a dynamo which again recharges the accumulator.

IV. Fuels.—Almost any kind of fuel, irrespective of impurities or of heat value, can be utilized in the internal combustion engine today. Fuel gases and fuel oils form ready mixtures with air and burn without considerable residue. Where gas is not available as a natural product or as the main or by-product of the industry, it can be economically produced from solid fuel in a special apparatus called a producer.

(A) Gaseous Fuels.— Small and medium-size gas engines are operated by one of the following kinds of gas — natural gas, illuminating or city gas, producer gas. Of these, the last two are artificially made. Large gas engines utilize mostly blast furnace gas, coke oven gas, and sometimes producer gas and natural gas. The heat values of these gases differ widely, as may be seen from table No. 2.

(a) *Natural Gas* is found in the oil districts of Pennsylvania and West Virginia. It exists in the earth in pockets and is reached by wells which are drilled to the pockets. In its natural state it is dry, clean and highly inflammable. For this reason it makes an ideal gas engine fuel when it can be obtained at low cost.

(b) *City Gas* is made from bituminous coal by dry distillation. After impurities, such as tar, have been carefully removed, it makes an excellent fuel for gas engines up to 50 horse power.

(c) *Producer Gas* can be manufactured from almost any kind of fuel, such as anthracite coal, bituminous coal, coke, lignite, wood refuse and peat. If the engine "draws" from the gas producer the gas required for its operation, the gas is called *Suction Producer Gas*. If air and steam are "blown" into the producer, and the gas thus made is under pressure, the latter is termed *Pressure Producer Gas*. Suction gas producer plants are by far in the lead in the United States and are mostly operated by anthracite. Their size rarely exceeds 200 horse power. The suction producer gas is cheaper than city gas, but on the other hand contains impurities which are liable to cause trouble in the operation of the plant. In Fig. 47 the construction of a suction producer plant is illustrated.

Air is drawn in through the generator, 1, filled with fuel, 3, the lower position of which is incandescent over the grates, 2. Water passes through the pipe, 4, into the evaporating pan, 5, surrounding the generator. This water is vaporized by the heat of the burning coal, 3. The steam thus formed passes down through pipe, 6, and together with air enters the generator through the grate, rising through the fuel and producing gas. The warm gas escapes through pipes, 7 and 8, into the lower part of scrubber, 10. Some of the impurities drop into the water trap, 9. Others are absorbed by the porous and bulky coke, 11, with which the scrubber is filled. A water spray entering at the top of the scrubber cools and purifies the rising gas. From a pipe, 12, the cooled gas passes through a tar separator, 13, into a small gas tank, 16, from which the gas is drawn by the engine as required. In starting, a hand operated blower is used for furnishing an air blast. During that period, the gas is directed by means of valve, 19, through the testpipe, 18, into the atmosphere. After having reached the proper quality, the gas is directed to the scrubber by turning the valve, 19, into the position shown.

Pressure producer gas plants range from 200 to 2,000 horse power. Mostly bituminous coal or lignite is used as fuel. The cleaning apparatus of such a plant must be more efficient than in the suction producer gas plant. In larger plants it is very economical to install a by-product plant for the treatment of the tar from which sulphate of ammonia and other products are obtained, thus helping to lower the cost of operation. Figure 48 illustrates a typical pressure producer gas plant.

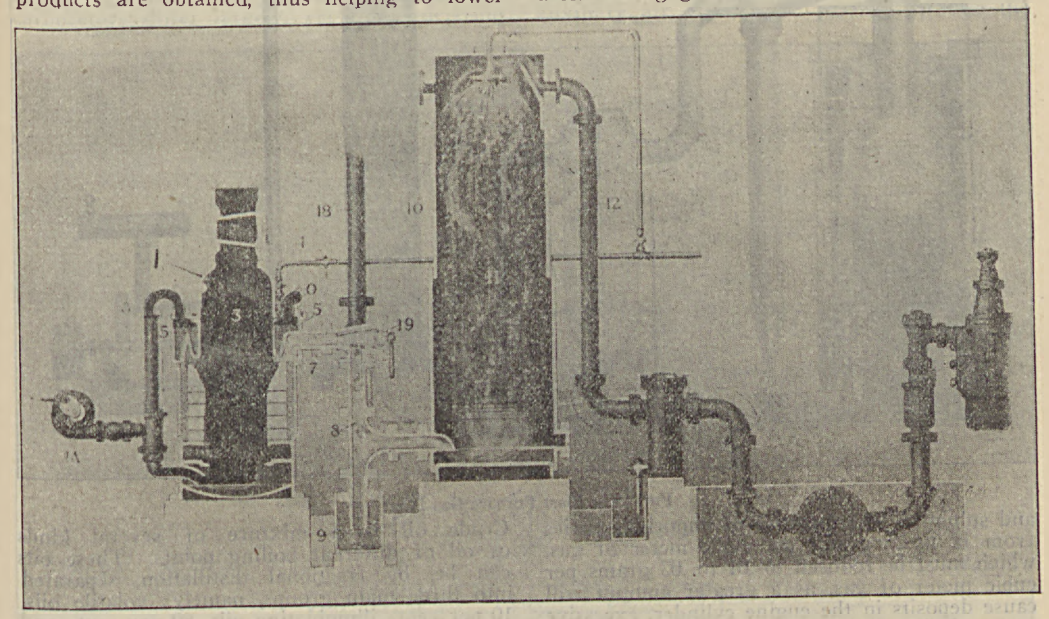

FIG. 47.— Suction Producer Gas Plant.

Steam is produced in a separate boiler, 19, from which it passes through pipe 6 into pipe 5 were it is mixed with air, previously heated in sprayed over the coke, cooling and purifying the rising gas. Through pipe, 12, the gas passes first through the tar separator, 13, then the drying filter, 14, filled with sawdust, and finally, after having gone through a second tar separator, 15, enters the gas tank, from which it flows, under slight pressure, to the engine. In case of a lignite plant, a steam boiler is not necessary, as the lignite contains sufficient moisture.

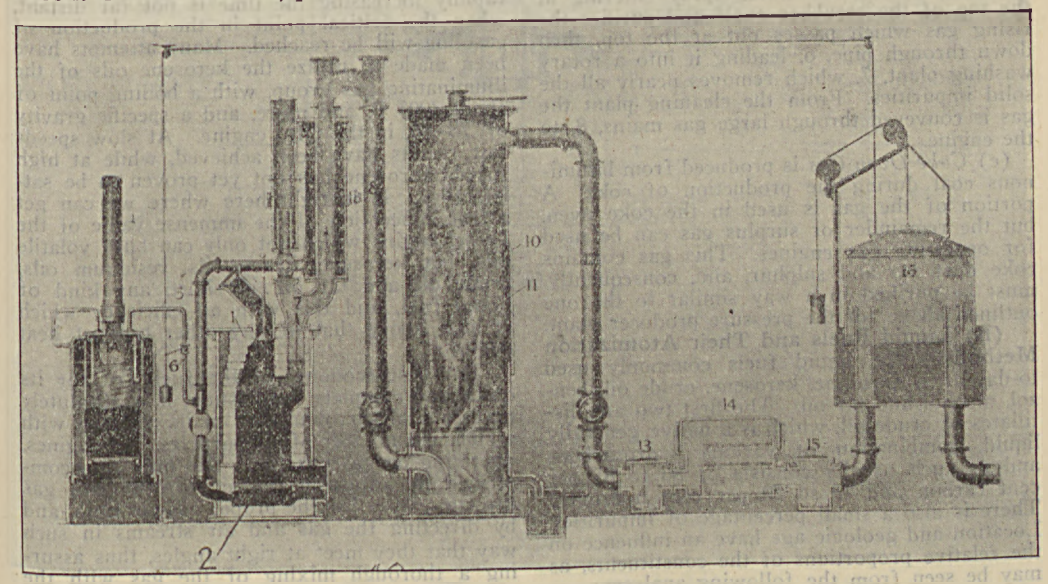

FIG. 48.— Pressure Producer Gas Plant.

tank, 1B. Steam and air together enter the generator, 1, through the grate 2. Rising through the incandescent fuel, 3, they form gas which is forced through pipes 7 and 8 into the scrubber, 10, filled with coke. Cold water is

(d) *Blast Furnace Gas.*—A blast furnace is, with regard to the production of gas, a huge pressure gas producer. The gas coming from the blast furnace contains a great quantity of impurities such as limedust, iron oxide, soot

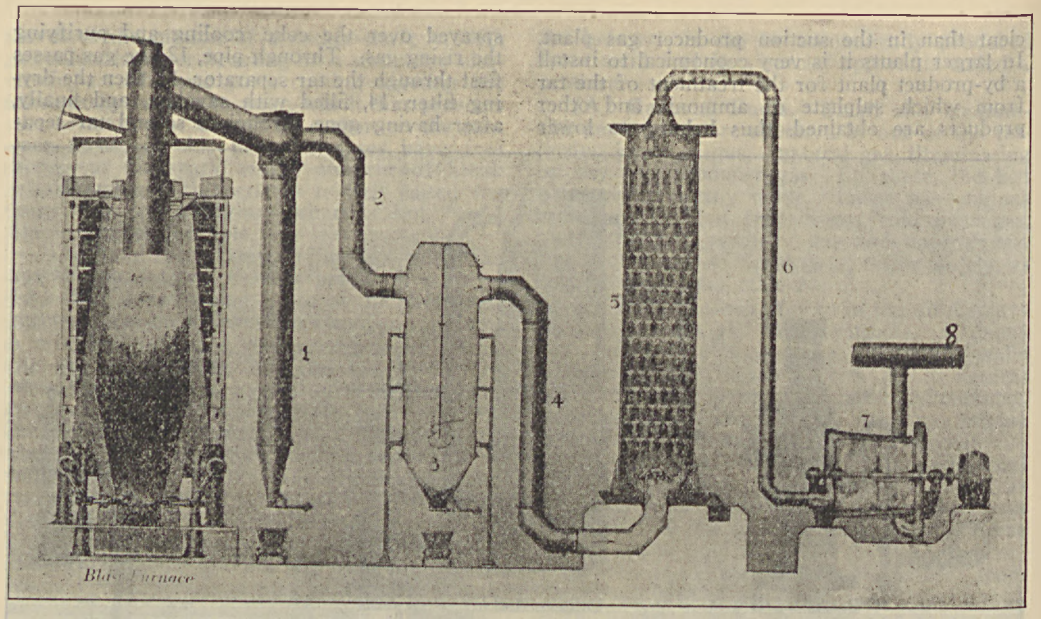

FIG. 49.— Blast Furnace Gas Plant.

and sulphur. The quantity of impurities varies from 12 to 25 grams per cubic meter of gas, which must be reduced to .01 to .03 grams per cubic meter of gas, as a greater amount will cause deposits in the engine cylinder, excessive wear of the moving parts and danger to the engine. A blast furnace gas cleaning plant is illustrated in Fig. 49.

After leaving the dust trap, 1, the gas passes through the pipe, 2, to a larger dust catcher, 3, continuing through pipe, 4, to the scrubber, 5. A cold water spray entering at the top of the scrubber cools and purifies the rising gas which passes out at the top, then down through pipe, 6, leading it into a rotary washing plant, 7, which removes nearly all the solid impurities. From the cleaning plant the gas is conveyed through large gas mains, 8, to the engine.

(e) *Coke Oven Gas* is produced from bituminous coal during the production of coke. A portion of the gas is used in the coke oven, but the remainder or surplus gas can be used for operating gas engines. This gas contains coke dust, tar and sulphur, and, consequently, must be purified in a way similar to the one outlined above for the pressure producer plant.

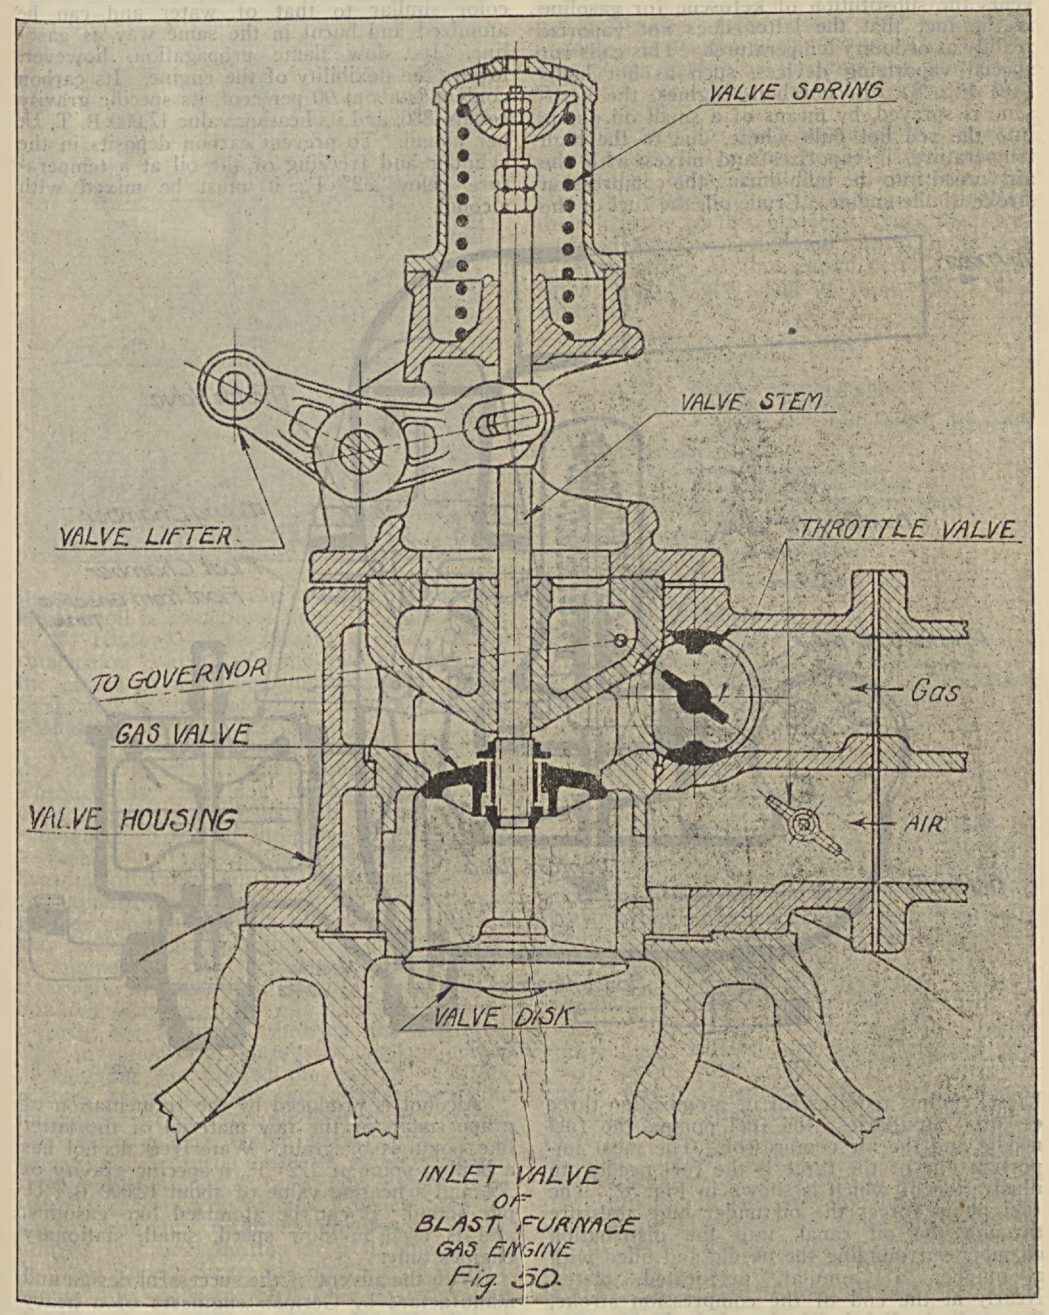
(B) Liquid Fuels and Their Atomization Methods.— The liquid fuels commonly used to-day are: Gasoline, kerosene, crude oil, benzol, alcohol and tar oil. The first two are distillates of crude oil, which is a native, generally liquid, combination of various hydrocarbons and as such usually consists of 80 to 85 per cent carbon and 15 to 20 per cent hydrogen. There is also a small percentage of impurities. Location and geologic age have an influence on the relative proportions of the constituents, as may be seen from the following analyses:

	Carbon, %	Hydrogen, %	Impurities, %	Heating value B. T. U.	Specific gravity at 32°
Heavy crude, West Virginia	83.5	13.3	3.2	18,324	.873
Heavy crude, Pennsylvania	84.9	13.7	1.4	19,210	.886

Crude oil is a mixture of several kinds of oil of different boiling points. These oils can be, by fractional distillation, separated into three main groups, namely: volatile oils, 10 per cent; illuminating oils, 80 per cent; and heavy oils. The first group contains besides other oils, gasoline with a boiling point of 160° to 200° F. and a specific gravity of .65 to .70. It is gasoline on which Otto engines, especially of the high speed automotive type, operate so successfully. With the number of automobiles rapidly increasing the time is not far distant, when the critical point in the production of gasoline will be reached. Many attempts have been made to utilize the kerosene oils of the illuminating gas group, with a boiling point of about 300° F. and more, and a specific gravity of .78–.86, in the Otto engine. At slow speeds fair results have been achieved, while at high speeds kerosene has not yet proven to be satisfactory. It is right here where we can get a true conception of the immense value of the Diesel engine which not only can burn volatile oils, but kerosene, heavy oils, residuum oils, crude oil and tar oil, in short, any kind of liquid fuel, and this with an efficiency which is high above that of any other type of heat engine.

For best economy of the fuel, i.e., for its quick and complete combustion, it is absolutely necessary to surround each of its particles with a sufficient number of air particles. In engines, operating on gaseous fuels, this may be accomplished by adjusting the air throttle and gas throttle valves for the proper gas-air ratio, and by directing the gas and air streams in such way that they meet at right angles, thus assuring a thorough mixing of the gas with the air. This is illustrated in Fig. 50. To accomplish the same aim with liquid fuel, the latter must be first atomized, assuring a more thorough amalgamation of the oil and air particles. Although almost any device which permits a current of air to pass over or through a volatile oil will serve the purpose, modern

gasoline-air mixing devices, termed carburetors, are called upon to deliver a mixture to the cylinders, which is not only of accurate proportion, but also of proper composition at all engine speeds. The details of the modern carburetors differ largely, yet the underlying



principle is mostly still that of the pioneer "*spray-jet*" automatic float feed carburetor evolved by Maybach about 35 years ago. A single spray-jet automatic float feed carburetor as used by the Packard Motor Car Company of Detroit is illustrated in Fig. 51. Gasoline flows into the float chamber through a needle valve. A constant height of the gasoline in the spray-nozzle connected with the float chamber is automatically maintained by the float. The suction created by the pistons causes air to enter the mixing chamber through the primary and auxiliary air inlets. In passing through the venturi tube the primary air assumes a speed of more than 7,000 feet per minute. It consequently draws gasoline from the spray-nozzle and atomizes it. The proper gasoline-air mixture, at all engine speeds, is maintained by the auxiliary air valve, the lift of which increases with the vacuum in the mixing chamber or with

the speed of the engine. Many attempts have been made to atomize kerosene by the methods described above, but they failed entirely in high speed engines. In small, slow speed, stationary engines, kerosene can be used with a fair degree of success. The chief difficulty which prevents the substitution of kerosene for gasoline is the fact that the latter does not vaporize readily at ordinary temperatures. This calls for special vaporizing devices, such as hot bulbs (see Fig. 8). In hot bulb engines, the kerosene is sprayed, by means of a small oil pump, into the red hot bulb where, due to the high temperature, it vaporizes and mixes with the air forced into the bulb during the compression stroke of the engine. Crude oil, the fuel of the countries, where gasoline and even crude oil are at a premium, benzol, alcohol and tar oil have come into extensive use. Benzol, a by-product in the manufacture of illuminating gas and coke is in its crude form a foul-smelling liquid. After the refining process it has a color similar to that of water and can be atomized and burnt in the same way as gasoline. Its slow flame propagation, however, lowers the flexibility of the engine. Its carbon content is about 90 per cent, its specific gravity equals .886, and its heating value 17,000 B. T. U. per pound. To prevent carbon deposits in the cylinder and freezing of the oil at a temperature below 32° F., it must be mixed with alcohol.

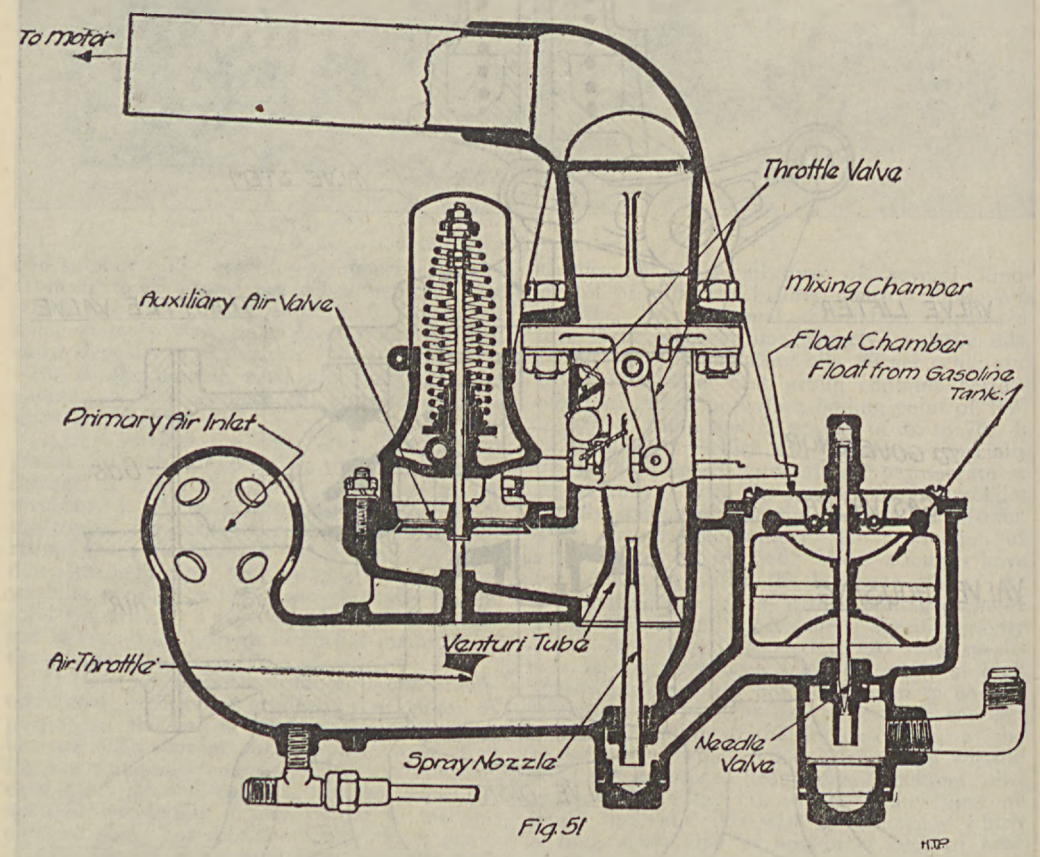


Fig. 51

Diesel engine, requires for its atomization three essential auxiliaries: the fuel pumps, the fuel needle and the air compressor. The most important one of the three is the fuel needle, an illustration of which is shown in Fig. 52. The fuel pump forces the oil under high pressure through the oil canal, into the distribution chamber surrounding the needle and filled with a number of annular, perforated, plates. Nearly at the end of the compression stroke, the needle is slightly lifted, and the highly compressed air, furnished by an air compressor through the air canal, forces the oil through the spray nozzle at a very high speed into the combustion chamber where a thorough mixing of the oil and air particles takes place. Hence the needle valve has two main functions: the distribution and the atomization of the oil. In

Alcohol is produced by the fermentation of grape sugar, or the raw material of the latter like potatoes or grain. Waterfree alcohol has a boiling point of 172° F., a specific gravity of .79, and a heating value of about 12,000 B.T.U. per pound. It can be atomized like gasoline, and is used in slow speed, small, stationary engines only.

With the advent of the successful design and manufacture by German engineers of a heavy type, horizontal, tandem, double acting Diesel engine, a new fuel has entered the market, tar oil. Of what importance this fuel is may be seen from that fact that Germany uses more than 500,000 tons a year in stationary engines. Tar oil is like benzol, a by-product in the manufacture of coke and gas. Its boiling poi... is about 600° F., its specific gravity about 1.0...

and its heating value about 17,000 B.T.U. per pound. All parts of the engine coming in contact with this fuel, like the fuel pump and spray needle valve, must be made of special material, as ordinary steel will be easily destroyed by it. To increase its flame propagation, ignition oil is sometimes used.

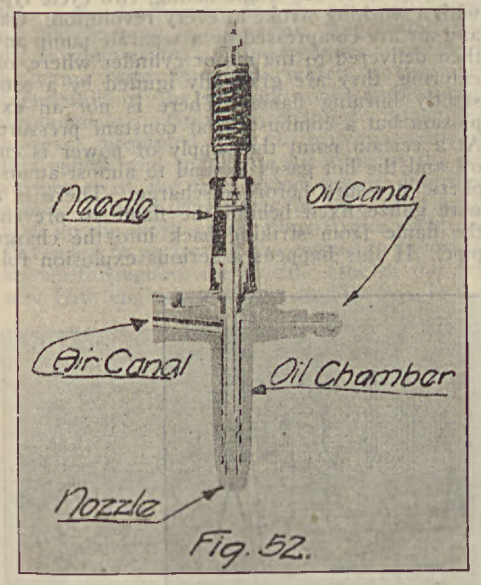

Fig. 52.

V. History.—The history of the internal combustion engine falls into two periods: (1) the period of invention and speculation, 1678–1860; and (2) the period of development and application, 1860 to date.

As early as 1678, Hautefeuille advanced the idea of the vacuum gun-powder pump. Through the explosion of gunpowder in a closed chamber provided with valves and the subsequent cooling of the gases of combustion, a vacuum is created, which is used for the drawing of water. In 1680, the same principle was applied by Huyghens in his vacuum gunpowder engine, in which atmospheric pressure was used for the operation of a piston. Such an engine was constructed and actually tested by Papin in 1688. For slightly more than a hundred years nothing was done, at least no records are available showing the contrary. The invention and successful application of illuminating gas toward the end of the 18th century seems to have again stimulated the interest of inventors in the field of the internal combustion engine. John Barber took out a patent on a gas turbine in 1791. Gases produced from solid or liquid fuels and mixed in a special chamber with air and a little water are ignited and the resulting impulse is to be utilized for the operation of a turbine wheel. In 1794, Robert Street invented the oil engine. Liquid fuel is evaporated in a cylinder and mixed with air taken in during the first half of the stroke. The mixture is ignited by a continuously burning ignition flame at the middle of the stroke and the piston is driven outward by the gases. From 1800 to 1860 many inventions along the internal combustion engine line have been made the most important of which are: the double acting illuminating gas engine of Lebon, 1801; the double acting explosion engine of Wright, 1833; the explosion engine with compression of Barnett, 1838; the hot tube engine of Drake, 1842, exhibited in Philadelphia in 1847 and having an output of 20 horse power at 60 R.P.M. and 103 pounds per square inch explosion pressure; the hydrogen gas engine of Reithmann, 1852, actually in operation in Munich until 1858; the atmospheric free piston engine of Barsanti and Matteucci, 1854; the gas engine with compression of Degrande, 1858.

Since 1860 the development of this type of prime mover was so rapid and its application so broad that it is impossible to mention here even the names of all the men who devoted their lifetime to this problem. Only the foremost ones can be considered. In order to give a better survey of this second period, the different engines are taken up in groups. Thus we have:

A. Gas Engines.
  (a) Without compression.
    (1) Direct acting.
      Example—Lenoir engine.
    (2) Atmospheric engines.
      Example—Otto and Langen free piston engine.
  (b) With compression.
    (1) Constant pressure engines.
      Example—Brayton engine.
    (2) Constant volume (explosion) engine.
      Example—Otto engine.

B. Gas Turbines.
  Example—Holzwarth gas turbine.

C. Gas Pumps.
  Example—Humphrey gas pump.

D. Oil Engines.
  (a) Without compression.
    Example—Otto and Langen engine.
  (b) With compression.
    (1) Constant volume (explosion) engine.
      Example—Otto-Daimler gasoline engine; standard automobile engine.
    (2) Constant pressure engine.
      Example—Diesel oil engine.

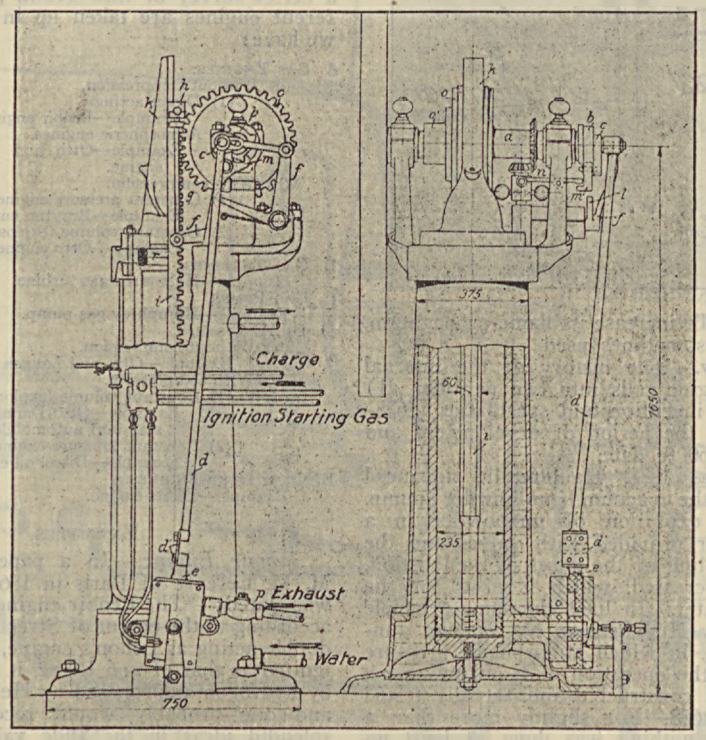
E. Coal Dust Engines.
  Example—Diesel engine.

Examples.

Lenoir Engine.—In a paper published by M. M. Lefevre of Paris in 1864 the following was stated: "The Lenoir engine uses the piston according to the patent of Street, it is direct and double acting as Lebon's engine, it is electrically ignited as that of von Rivaz, it can be operated by hydrogen as proposed by Herskine-Harzard, and one probably would recognize Talbot's splendid ideas in the slide valve as used by Lenoir. But the Lenoir engine draws in gas and air itself without previous mixing and that constitutes its patent claims." Lenoir's original engine was modeled after the standard steam engine, had a 3-inch bore, 5-inch stroke and a speed of 100 revolutions per minute. It was without a water jacket, had a continuously sparking ignition plug, located in the middle of the cylinder and laid bare by the piston, thus igniting the mixture in the front and back end alternately and giving off power during the second half of the stroke only. Its fuel consumption was high, and its over-all efficiency from 3 per cent to 4 per cent.

Otto and Langen Free Piston Engine.—Among the most zealous of those who tried to improve the gas engine was a young merchant, N. H. Otto of Cologne. Through experiments in 1861 and 1862 he learned that cooling the gases caused a great decrease in volume, and consequently a partial vacuum. Otto endeavored

to use this for the generation of power. After many tedious experiments he and his partner, E. Langen, to whom we owe the systematic development of this engine, succeeded in perfecting an engine, shown in Figs. 53 and 54. The striking feature of this engine is the use of a free piston connected with the flywheel shaft, *a*, by means of rack, *i*, and pinion, *o*, which runs freely on the shaft while the piston is on its upward stroke, but, by an ingenious clutch arrangement, it grips the shaft on the down stroke. The valve, *e*, by one in- and out-stroke, causes the exhaust, intake and explosion in the order named. It is moved by rod, *d*, connected to crank, *c*. The elastic connection, *d*, is unique and is worth notice. Levers *f* and *g* lift the piston and the charge enters through slide valve, *e*. After the piston has made a stroke



FIGS. 53, 54.— Otto and Langen Free Piston Engine.

of a few inches the valve, *e*, carries the ignition flame to the inlet port causing a sudden combustion of the charge within the cylinder. The power developed drives the piston upward with a maximum velocity of over 2,000 feet per minute. Due to over expansion and cooling of the gases a vacuum is created below the piston, and, on the down stroke of the piston, work is done by the atmosphere and the weight of piston and rack. This free piston engine was exhibited at the Paris Exposition in 1867. Laymen were even afraid of the instantaneous ascent of the rack, and experts criticized severely the awkwardness and noise of the engine. After a competitive test with 14 other gas engines, in which it showed an over-all efficiency of 15 per cent, opinions suddenly changed. It completely crushed Lenoir, and held almost the sole command of the market for 10 years, several thousands being constructed in that period.

Brayton Engine.— This engine is an American product and was introduced to the public by Brayton at the exhibition in Philadelphia in 1878. It is of the single acting, two cycle type with a working stroke at every revolution. Gas and air are compressed by a separate pump and then delivered to the motor cylinder where, on entering, they are gradually ignited by a constantly burning flame. There is not an explosion but a combustion at constant pressure. At a certain point the supply of power is cut off and the hot gases expand to almost atmospheric pressure before discharge. There is a wire gauze fixed behind the flame to prevent the flame from striking back into the charge pipe. If this happens a serious explosion follows, stopping or wrecking the engine. On this account Brayton abandoned the use of gas and substituted light oils. Although the danger of explosion was thus removed, new difficulties arose due to the rapid accumulation of soot in the cylinder which cut the latter. A great number of Brayton engines have been built by the Ready Motor Company of New York. The over-all efficiency of this engine was about 6 per cent.

Otto Engine.— Otto's aim was to use the entire stroke for the explosion and expansion. To obtain this he built an experimental machine in which the engine turned forward for the intake; then the valves were closed and the flywheel turned backward to compress the mixture, which was then ignited by hand. The effect was surprising. The ignited mixture, on account of the compression, exploded with such

violence that the wheel rotated for some time at high speed. This was the more surprising, since, when the engine was operated without compression, it ran at a low speed. So by these experiments, 1861–62, Otto arrived at the compression of the charge before explosion, ignition at the dead-centre and the accomplishment of the charging, compression, combustion and discharging events in one cylinder — in short, he came onto the cycle which is the very foundation of the internal combustion engine development. Great mechanical difficulties, however, prompted Otto to drop his work on this engine and to devote his time to the development of the free piston engine described above. Fifteen years later, in 1877, Otto again took up the work on the four-stroke cycle and succeeded in perfecting the engine so favorably known throughout the world. One of the first new Otto engines is shown in Fig. 55. It is a

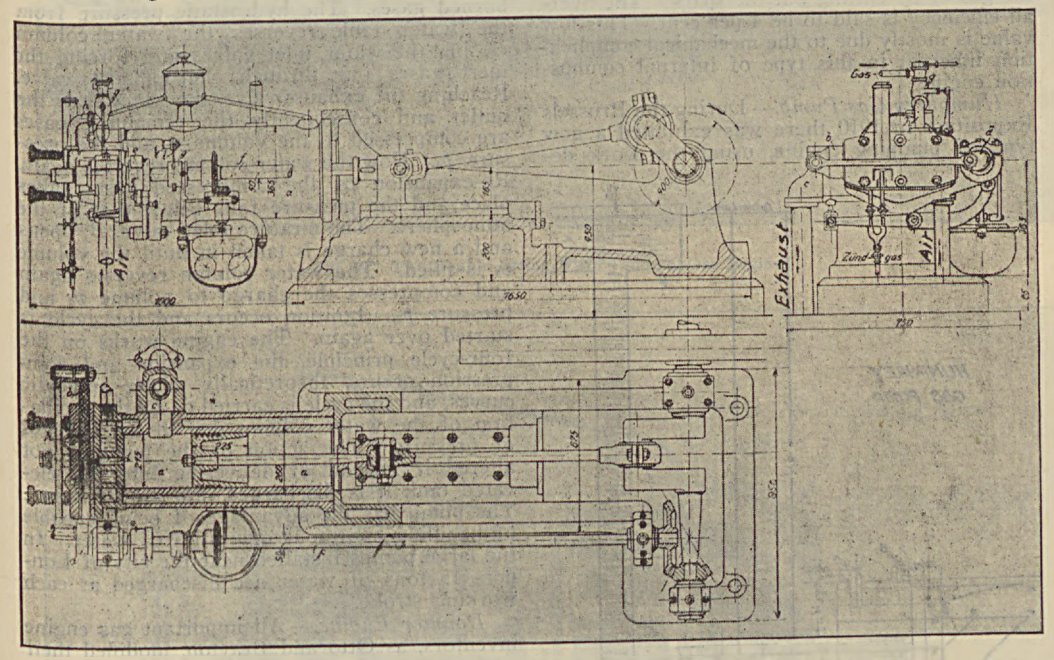


FIG. 55.— Otto Engine, built 1884, 8 B.H.P. at 170 R.P.M.

horizontal, one-cylinder, four-stroke cycle gas engine, consisting of cylinder with water jacket, piston, piston-rod, crosshead, connecting-rod, crankshaft, flywheel, frame and timing gears. The cylinder has a clearance space, *a*, of about two-thirds of the piston displacement. The entrance of the gas and air, as well as the ignition, is controlled by the slide valve, *b*. Exhaust takes place through the valve, *c*, both valves being operated from the half-speed shaft, *f*, by means of the crank, *d*, and the cam, *e*, respectively. The gas valve, *g*, is operated by the cam g^1. At the beginning of the intake stroke the exhaust valve, *c*, is closed, while the slide valve, *b*, has moved its air canal to communicate with the channel, *i*, of the cylinder head. Air alone is drawn in for the first part of the stroke, which is supposed to force the burnt gases of the clearance space against the receding piston. In the meantime the valve, *l*, has moved far enough to open the gas inlet, while the cam, g^1, has opened the gas valve, *g*, so that gas and air enter the cylinder simultaneously at the end of the stroke. Now the slide valve, *b*, closes the port, *i*, and the charge is compressed into the clearance space by the returning piston. During this time the slide valve, *b*, has moved to the right, and the ignition port, *h*, is opposite the port, *i*, so that the flame is carried through, *i*, into the clearance space, *a*. Ignition occurs on dead centre and combustion takes place at almost constant volume. At the end of the expansion stroke the valve, *c*, is opened and exhaust occurs during the next stroke. The burnt gases in the combustion chamber cannot be expelled, but remain and become a part of the next charge. Governing is by the "hit and miss" principle. The carrying out of the four-stroke cycle in the Otto engine is mechanically almost perfect. The over-all efficiency was about 15 per cent in small sized engines, increasing with capacity of cylinder and improvement of construction. To-day Otto engines show over-all efficiencies of 28 per cent to 30 per cent. In 1878 the largest engine sold was 4 horse power; 1880, 20 horse power; 1885, 80 horse power; 1889, 100 horse power; 1893, 200 horse power; 1900, 1,000 horse power; in 1912, 6,000 horse power in the double-acting four cylinder units were delivered. Fig. 56 illustrates a double-acting, four cycle, high-powered gas engine of American make.

Holzwarth Gas Turbine.— The recent great success of the steam turbine has aroused not less interest in the internal combustion turbine again, while from a thermodynamical point of view the problem of the gas turbine is not worse and not better than that of the reciprocating gas engine, however, the mechanical aspects offer less encouragement. The combustion of fuel in the gas turbine may take place at constant volume without or with com-

pression of the charge or at constant pressure. The only gas turbine of considerable size which has yet appeared is the one systematically developed by Hans Holzwarth. It is of the explosion (constant volume), compressed charge type with a nominal output of 1,000 horse power at 3,000 revolutions per minute, gas and air are separately compressed by compressors and forced into a number of combustion chambers arranged annularly around a vertical shaft, on which a horizontal turbine wheel is fixed. Each combustion chamber contains gas and air inlet valves, spark plugs and a nozzle valve. The latter is closed during the charging period. The explosion pressure forces it open, thus enabling the high-tension gases to pass through the small nozzle on the turbine wheel at high velocity. After having given up their energy to the wheel the burned gases escape into the atmosphere. Governing is effected by throttling the gas or by cutting out the spark. The overall efficiency is said to be 4 per cent. This low value is mostly due to the mechanical complication inherent in this type of internal combustion engine.

Humphrey Gas Pump.— During the Brussels Exposition in 1910 there was exhibited a new type of pumping engine, using the work de-

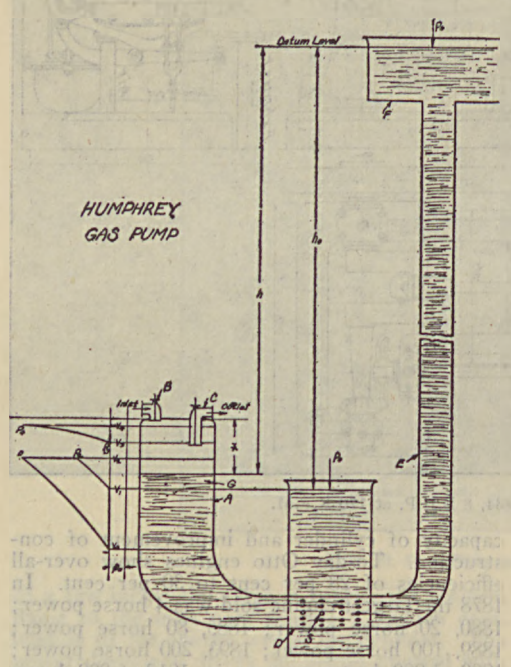

FIG. 56.

veloped by the explosion of a gas-air mixture for the lifting of water. It is known as the Humphrey Gas Pump. Since that time this gas pump has gained a world-wide reputation. It has been introduced into this country and greatly improved by American designers. Its operation can best be understood by reference to Fig. 56. The pump consists of a vertical gas cylinder, *A*, with inlet and outlet valves, *B* and *C*. These valves interlock with each other. On the water side of the pump there is a suction pipe, *D*, a number of suction valves, *S*, and a pressure pipe, *E*, connecting the cylinder with the pressure tank, *F*. The water column, *G*, forms a gas-tight piston. To start the engine the combustion chamber must be filled with an explosible gas-air mixture, having the pressure, p_2. This mixture is ignited and the pressure, due to the combustion, suddenly increases to p_1. While this takes place the volume will scarcely change so that combustion practically occurs at constant volume. The water column, owing to the increased pressure on its surface, is rapidly accelerated and the gases expand to volume v_0 and pressure p_0.

As soon as the gas pressure has become less than that of the atmosphere the exhaust valve on the top of the cylinder and the suction valves on the water inlet tank begin to open automatically. The inflowing water follows the moving water column and fills the gas cylinder up to volume v_1, thus partly replacing the burned gases. The hydrostatic pressure from the water tank reverses the water column closing the water inlet valves and forcing the inert gases out through the exhaust valve. Reaching the exhaust valve, the water seals the outlet and consequently the remaining gases are compressed to the volume v_4 and the pressure. p_4. Now the water column reverses again. Re-expansion of the compressed gases takes place and the pressure falls below that of the atmosphere. The mixture inlet valve, *B*, opens and a new charge is taken in until the volume v_1 is filled. The water column reverses again and compresses the charge to volume v_2 and pressure p_2. Ignition occurs and the cycle is started over again. The engine works on the four-cycle principle, the expansion and compression occurs, theoretically, along adiabatic curves, and the cycle is carried on by the oscillation of the water column due to the changes of pressure. The action of the pump is not altered if instead of delivering into the elevated tank it is discharged into an air vessel. The pump has the advantage of being capable of handling enormous quantities of water. In the large pumps installed near the city of London, 15 tons of water are discharged at each working stroke.

Daimler Engine.— All important gas engine inventors, as Otto and Brayton, modified their engines in order to use liquid fuel. It remained, however, for Daimler, the pioneer automobile engineer and former manager of the Otto Gas Engine Works, to develop the first gasoline engine of the Otto type for automotive work. The main characteristic of the Daimler engine was its high speed. Contemporary gas engines were running at 150 revolutions per minute, while Daimler increased the speed to 800 revolutions per minute. This meant a considerable reduction in weight at equal power output, yet, on the other hand, a higher strain was set up in the various parts of the engine, necessitating better materials of construction. Thus the Daimler engine incidentally gave also the impetus for the development of high-grade materials without which the present day automotive engines would be impossible. Daimler's first engine, built in 1884, was of the horizontal one-cylinder type, and differed from the original Otto engine only in speed, weight, fuel and valve gear mechanism. Later he constructed vertical engines of the twin cylinder V-form,

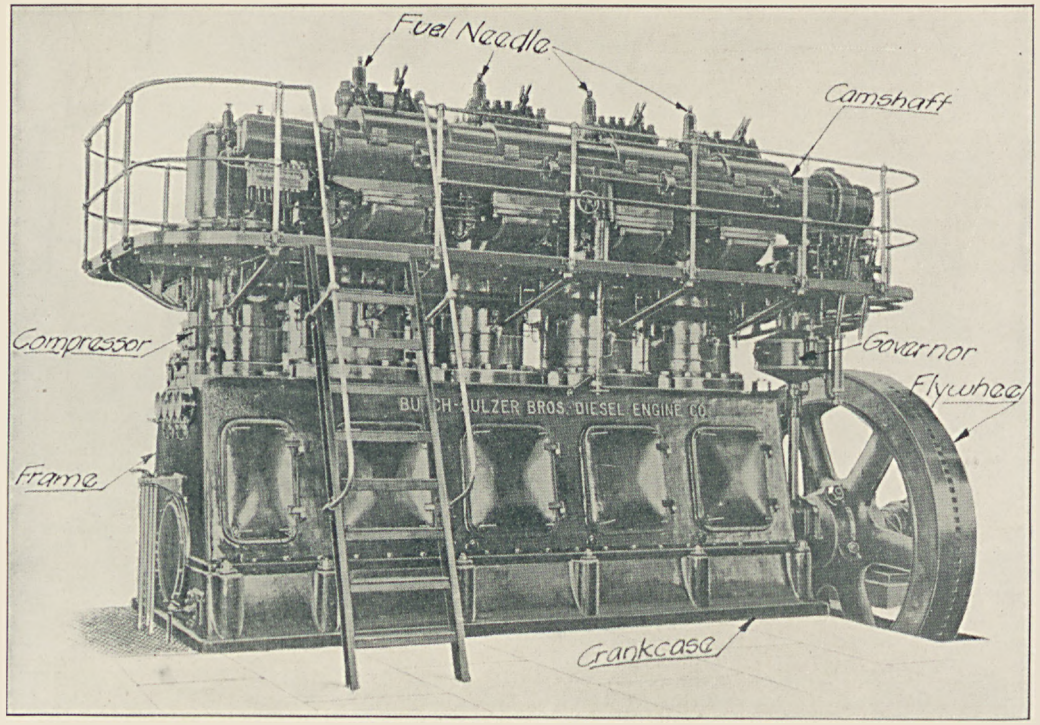

Fig. 63 520 Brake Horse Power—Diesel

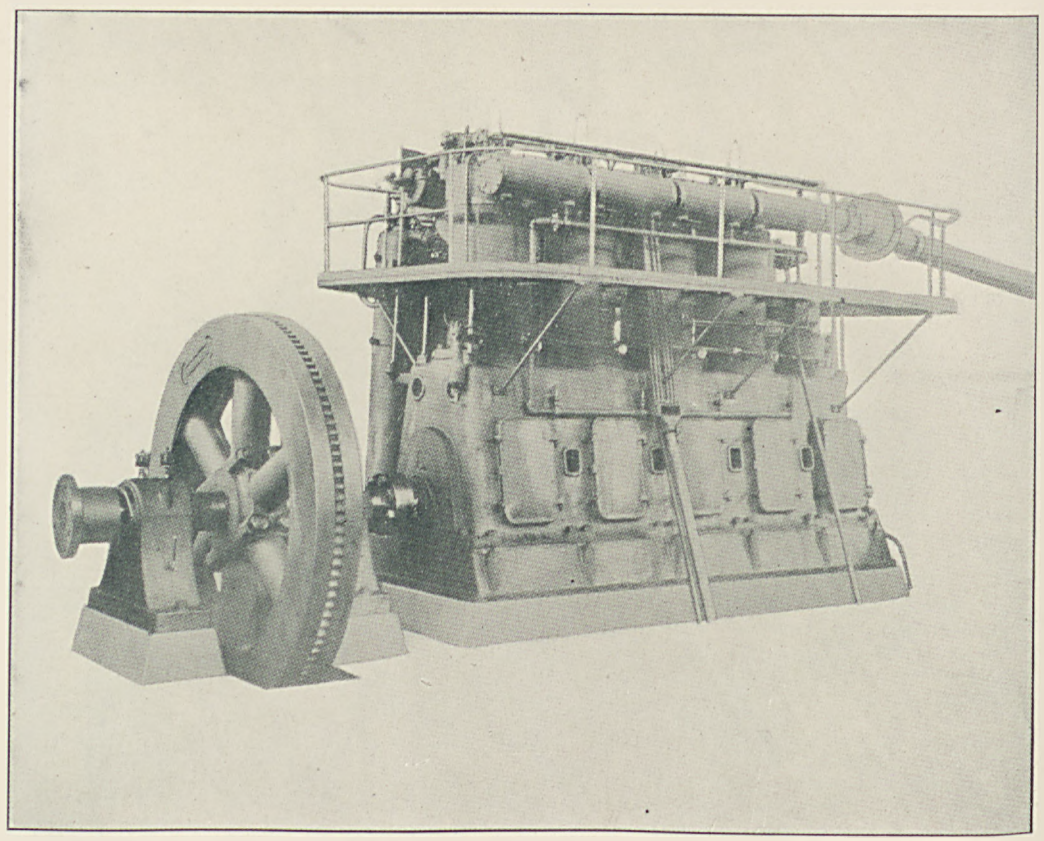

Fig. 64 Type B stationary engines have a single box frame for the entire set, as shown in the illustration, with a multiple-stage air compressor for the fuel injection driven directly from a crank on the end of the main shaft

and the four cylinder all in line type. The latter has gradually been developed to the standard automobile engine of to-day (see Fig. 58), running at a speed of 600 revolutions per minute to 3,000 revolutions per minute. Starting at the left and upper part, cylinder No. 1 is the outside view. Cylinder No. 2 is cut away at the front, showing the poppet valves, H and H_1, controlling inlet and outlet of gases, respectively; the valve chamber, H_4 and H_5; the valve seats, H_6 and H_7; the spark plug J_1; valve springs, S; the push rods, H_2 and H_3; the push rod guides, H_8 and H_9; and the cams, G_3 and G_4. Cylinder No. 3 is cut through its centre, thus showing the piston, B; the wrist-pin, B_8; the connecting rod, C; the cylinder, A; the waterjacket, K; the combustion chamber, A_3 and the cylinder head A_1. The crankshaft, F, is a high grade steel forging and has three main journals, F_2, and four crankpins, E. The valve timing or half-speed cam shaft, G, driven through gear, G_5. by pinion, F_4, on crankshaft, F, has three main bearings, G_2. The four inlet cams G_3, and the four outlet cams, G_4, are fixed to this shaft. At the lower end of each of the connecting rods, C, is a splasher or oil dipper, C_5. The crankcase, M, encloses the base of the engine. Splash troughs, L, are in the bottom of the crankcase beneath each connecting rod, C. The oil reservoir, or sump, M_1, is located beneath the crankcase. The parts requiring lubrication are the crankshaft bearings, crank-pin bearings, piston pin bearings, cam-shaft bearings, timing gears, cams, valve-lifter guides, pistons, piston rings and cylinder walls.

In almost all gasoline engines the intake of fresh gas to the cylinder and the exhaust of the

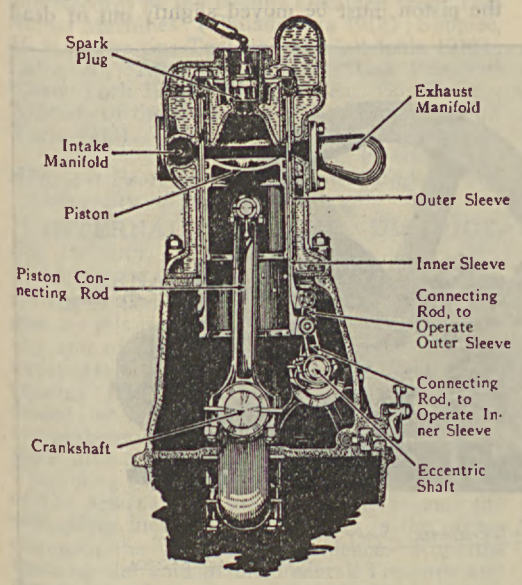

Fig. 59.—Sectional View of Cylinder in Willys-Knight Motor.

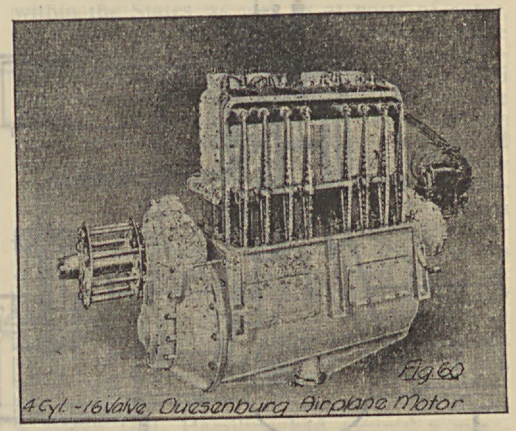
inert gases from the combustion chamber are governed by clashing "poppet" valves. These valves are rather noisy. To eliminate this noise in automobile engines, Charles Y. Knight invented "sleeve valves" also known as the Knight valves, which, besides offering other advantages, have proved to be noiseless. Two cylindrical sliding valves glide silently up and down between the cylinder wall and the piston, one working within the other. Ports or openings in these sleeves register with each other and with the cylinder ports at proper inter-



vals, forming large and unobstructed passages for intake and exhaust gases. The operation of the sleeve valves is clearly explained in the accompanying illustration, Fig. 59. Fig. 60 shows a four cylinder four-cycle gasoline engine as adapted to airplane requirements. The weight of the engine has been reduced to three and one-half pounds per horse power. At a normal speed of 2,100 revolutions per minute the engine develops 125 horse power with a bore of four and three-quarter inches and a stroke of seven inches. By means of a gear reduction, the speed of the propeller shaft is reduced to 1,210 revolutions per minute.

Diesel Engine.—Dr. Rudolph Diesel of Munich, Bavaria, published in 1893 a book: "The Theory and Design of a Rational Heat Engine," in which he described the principles of an ideal internal combustion engine, for the efficient operation of which he formulated the three main requirements. (1) Creation of the highest temperature in the cycle by mere compression of pure air and not by combustion of the charge. (2) Gradual introduction of atomized fuel into the highly compressed and consequently highly heated air in such a way that the temperature of the charge remains constant. (3) Proper selection of the air-gas ratio to allow a practical operation of the engine without using a waterjacket.

The compression pressure of this ideal engine was 250 atmospheres and the thermal efficiency 73 per cent. Dr. Diesel expected considerable trouble due to the high pressures, consequently he proposed another "approximatively ideal" cycle with lower compression pressure and efficiency. Patents granted to Diesel enabled him to form a partnership with the Maschinen Fabrik Augsburg and Friedrich Krupp of Essen. After several years of very difficult and tedious experimental work, Diesel found out that his ideal engine could not be realized. The oil engine, however, which was developed by him and his associates between 1893 and 1898 showed an over-all efficiency of 32 per cent, and thus turned out to be by far the most efficient heat engine yet built.

In Figs. 61 and 62 an early type of Diesel engine working on the four-stroke principle is illustrated. The main parts of the engine can be clearly recognized in the transverse section Fig. 61. They are the crankcase, the frame

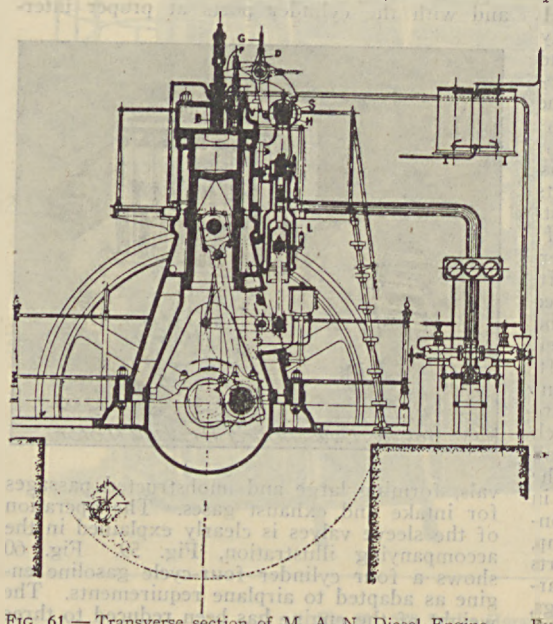


FIG. 61.— Transverse section of M. A. N. Diesel Engine.

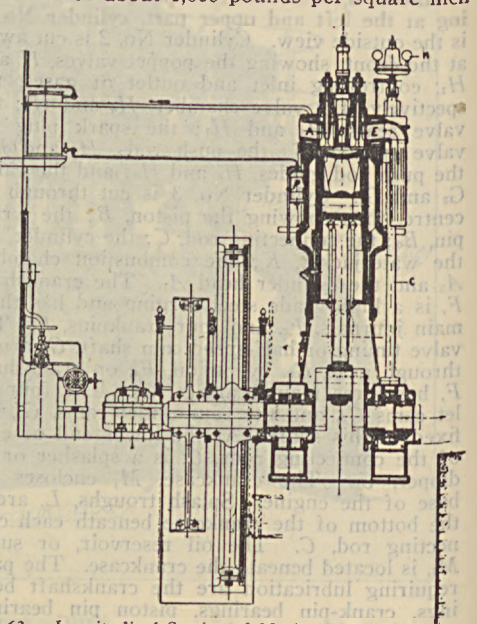

FIG. 62.— Longitudinal Section of M. A. N. Diesel Engine.

with waterjacket; cylinder liner and cylinder cover, the piston with the wristpin, connecting rod and crankpin, the two-stage air compressor, *L*, driven by the connecting rod by means of a walking beam, the camshaft, *H*, with the cams, bearings, the vertical shaft, *c*, driving the horizontal camshaft, *H*, and the governor, *M*, the air inlet valve, *E*, and the exhaust valve, *A*. The air furnished by the air compressor at a pressure of about 1,000 pounds per square inch must be cooled before it is stored in the air flasks. By means of pipes the compressed air is carried from the flasks to the starting valve, *F*, and the fuel needle, *B*. To start the engine the piston must be moved slightly out of dead

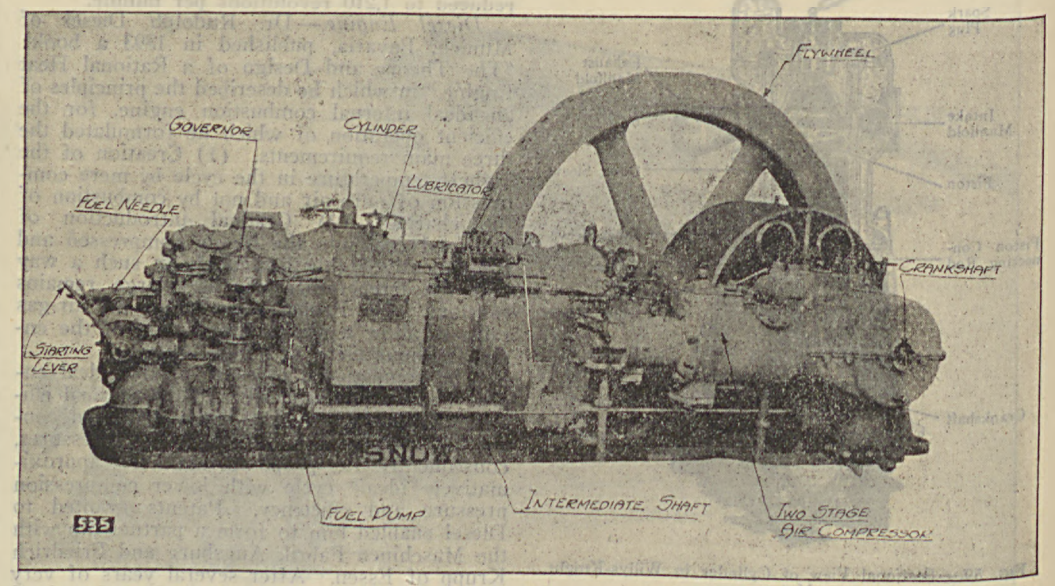

FIG. 65.— 170 H.P. Two-Cycle Diesel Engine, One Cylinder, Horizontal Type.

S, and the fuel pump (not shown), the starting valve, *F*, and the fuel needle, *B*, operated by the levers *D* and *V*, respectively. In the longitudinal section Fig. 62 there are shown the crankshaft with flywheel and pulley, the three centre and the hand lever, *G*, laid down in the horizontal position. This throws the needle valve out of action and brings the lever arm *D* in contact with the starting cam, thus putting the starting valve in operation and allowing compressed air to enter the cylinder. The piston begins to move down and the speed of the engine increases. After the latter has made several revolutions the hand-lever *G* is turned back into the vertical, the operating position, in which the fuel needle is in regular operation and the starting valve at rest.

In this country the Busch-Sulzer Bros.-Diesel Engine Company is the original and was, from 1898 to 1911, the only company manufacturing Diesel engines in America. It owns all United States patents granted to Dr. Rudolph Diesel, and is closely associated with the old firm of Sulzer Brothers of Winterthur, Switzerland, with which it is in intimate cooperation. After the original United States Diesel patents had expired in 1912, many other engine concerns took up the manufacture of the Diesel engine. Figs. 63 to 65 illustrate some recently designed Diesel engines of American make.

INTERNAL REVENUE DISTRICT.

See DISTRICT.

INTERNAL REVENUE SYSTEM.

The system of taxation in the United States, which goes by this name, was the outgrowth of necessity and of the administrative genius of Alexander Hamilton. The law of 2 Sept. 1789, creating the Treasury Department, had been drawn by him, and with such precision and comprehensiveness that but few changes have since been made in its substance or language. The young Secretary considered it to be the duty of the new national government to assume the obligations incurred by the States in the prosecution of the War of Independence. Notwithstanding the void in the Federal Treasury and the straitened finances of the country at large, he had prevailed on Congress, after a bitter struggle, to become responsible for the payment of about $24,500,000 of debt, which the States were unable to meet and had practically repudiated. The new government itself was little better off. The revenues from customs were inadequate; the nation was poor and imports were small. Hamilton's suggestion was to place an excise on domestic distilled spirits. Though there was as yet no formal differentiation of political parties, the antagonism between the broad and strict constructionists of the Constitution was already manifesting itself. The design of the Secretary to exercise, within the States, as well as at ports of entry, the taxing powers which he believed to reside in the Federal government, met with strong resistence from the Anti-Federalists, who regarded the project as unwarrantably intrusive into the domestic affairs of the States. Moreover, the opposition obtained the support of powerful business interests and of a considerable body of public opinion. There were about 100 distilleries in Massachusetts alone, most of them in Boston, where West Indian molasses (exchanged by Yankee traders for their exports of fish and lumber) was converted into New England rum. In the West and South whisky was made from grain at hundreds of stills in commercial quantities. Rum and whisky were articles of general consumption. The first bill, introduced in Congress in 1790, was defeated; but before the end of the session, by the act of 3 March 1791, Hamilton had secured a measure imposing a tax on distilled spirits, graduated from 11 to 30 cents per gallon, according to alcoholic content and the origin of the raw material, domestic or foreign. Although the impost weighed more heavily on rum, made from imported molasses, than on whisky made from home-grown corn, the demonstrations against it became particularly violent in the Alleghany and Cumberland mountain regions. In September 1791 a revenue officer was tarred and feathered in western Pennsylvania, as a defiance of the government. The incipiency, progress and suppression of the Whisky Rebellion (q.v.) it is not proposed here to discuss. Suffice it to say that, when it collapsed in September 1794, it left the right of the Federal government to levy excise on domestic products and within the States firmly established. The right to tax whisky was never thereafter questioned, except by the «moonshiners» of the Appalachian highlands, whose conflict with the «revenuers» has continued to this day.

Having obtained recognition for the principle, Secretary Hamilton proceeded to give it wider application. An excise laid in 1794 on carriages used for pleasure or ostentation was assailed as unconstitutional; but the Supreme Court (Hylton *v.* U. S., 3 Dallas, 171) sustained the act. The objection that the tax, being direct, should have been apportioned among the States according to population, evoked from the court the remark, that the only taxes it could conceive to be direct were head taxes and land taxes. In 1794 also laws were passed imposing excise taxes for selling at retail foreign wines and liquors; an excise of 8 cents a pound was laid on snuff; an internal revenue duty of 2 cents a pound was laid on sugar refined in this country, also a tax on sales by auction. By the law of 6 July 1797, «stamped vellum, parchment or paper» was required to be used for a great variety of legal documents and negotiable instruments. In these several laws the internal revenue system, as it ultimately took form, was broadly outlined. All of these enactments were repealed, however, on 6 April 1802, little more than a month after

the inauguration of Jefferson as President and the ouster of the Federalists. The revenue derived from internal taxes in the few years they were actually collected amounted to $6,325,000, besides which about $700,000. though assessed remained unpaid at the time of the repeal. The financial necessities of the government, occasioned by the War of 1812, compelled recourse once more to forms of taxation other than customs dues. Nearly all the excises of Hamilton's internal revenue system were reimposed in 1813 and, for the first time, home industries other than the distilleries and snuff factories were taxed. There was a new tax on carriages, now including the harness; on boots and leather, beer, candles, caps and hats, parasols and umbrellas, paper, playing cards and saddles and bridles; also on watches, jewelry, gold, silver and plated ware. Stamped paper was required for bonds, bills, notes and other commercial instruments. Here are all the incidences of taxation, which have become characteristic of the internal revenue system; but its mainstays, then as later, were the whisky and tobacco taxes. After the war they were all repealed and, thenceforward, until 1861, the ordinary revenues of the Federal government were derived exclusively from the customs.

The act of 5 Aug. 1861 was primarily intended to (temporarily) increase duties on imports; though it also imposed a direct tax of $20,000,000, to be assessed on land and collected for the government by the States. The law of 1 July 1862, however, which is entitled: "An act to provide internal revenue for the support of the government and to pay interest on the public debt," was a conscious effort to establish a new system of Federal taxation. It created the office of Commissioner of Internal Revenue in the Treasury Department and provided for an organization of collectors and inspectors, which has been maintained substantially as first organized up to the present time. The tax on whisky was fixed by the Internal Revenue Law, as the act was called, at only 20 cents per proof gallon, probably following the precedent of the law of 1813; but this tax was increased by three successive enactments in 1864, first to 60 cents, then to $1.50 and, finally, to $2 per gallon, where it remained until 1868. The newly developed oil industry received marked attention, for quite as heavy a tax was placed on illuminating and lubricating mineral oils (20 cents per gallon) as was originally placed on whisky; moreover, refiners of oil were subjected to all the provisions applicable to distillers of spirits with respect to special (license) taxes, bonds, returns, assessments and removals to and withdrawals from warehouses. All other illuminants then in common use, such as gas and candles, were likewise taxed, but this accorded with the general policy of the act to obtain revenue from everything in sight. It taxed bar, hoop and sheet iron, steel, wire, wood screws and cut nails; locomotives and marine engines and boilers; brass tubing and lead pipe, textile fabrics, clothing and trimmings, felt hats, silk hats and bonnets, hides, leather and factory-made shoes, hoopskirts, diamonds, jewelry, watches and gooseberry wine; also sugar, ground spices, chocolate and dry mustard. The products of domestic agriculture, cotton excepted, went free and farmers were unlicensed; but special, or license, taxes were placed on practically all other occupations. The butcher, the baker and candlestick maker (this is a literal truth) had to pay, and so did the doctor and lawyer. The stamp taxes were expected to yield $20,000,000 a year, but they produced twice that amount. All legal documents, all kinds of commercial instruments, including checks and receipts, bonds, insurance policies, conveyances and mortgages had to be stamped; and, if unstamped, the law declared them void and forbade them being placed on record or used as evidence. The law also imposed dues on successions and legacies, and a tax of from 3 to 5 per cent, graduated to their amount, on incomes. Most of these were, and so intended to be, war taxes. Reductions began to be made in 1866 by the first Congress that met after the restoration of peace. Many of them were abolished in 1867 and 1868 and practically all of them, including the tax on incomes (but excluding the stamp taxes and the excises on whisky, tobacco and beer) were lifted by the law of 14 July 1870.

The Internal Revenue Act and its successful enforcement had demonstrated the wide scope of the taxing powers of the Federal government. Its right to levy tax on incomes was not successfully assailed until 1914, when the Supreme Court declared the Income Tax Law passed that year to be unconstitutional. Most of the stamp dues were abolished in 1872, the longest to continue being those on checks, toilet articles, patent medicines and playing cards. The taxes on whisky, beer, manufactured tobacco and cigars became the enduring features of the Federal system of internal taxation; and they were the most productive. The largest amount collected under the Internal Revenue Law of 1862 in any year was in 1866, before any of the war taxes had been abolished, when $310,000,000 was turned into the Treasury from this source. The total collections in the 30 years following 1864, when the original act of 1862 obtained its final form, amounted to approximately $4,550,000,000, of which two-thirds was derived from whisky, beer and tobacco. By the act of 13 July 1866, stamps were first required to be affixed to beer kegs as evidence of payment of the tax on the contents. The result was so satisfactory, in this particular, that two years later tax-paid stamps were required to be affixed to the original packages of distilled spirits when taken out of bond, and to each box or other container of cigars and manufactured tobacco before the goods left the factory where they were made. As a substitute for, or as an additional check on, the elaborate systems of accounting employed to prevent frauds on the revenue, the tax-paid stamp has abundantly proved its usefulness. Its efficiency came into question in 1875, when the "Whisky Ring" trials disclosed a jugglery with distillers' and rectifiers' stamps (which are not tax-paid but merely certify the contents of the packages) whereby the government had been defrauded of many millions. The success of the frauds was due, however, to the corruption of revenue officers as well as to defects in the stamp laws. Since the introduction of new checks, suggested by the experience with the "Whisky Ring," there have been no serious losses in the collections. This is remarkable in view of the fact that the tax on distilled spirits, which was finally set at $1.10 per gallon, where it remained fixed for 40 years, amounted to about four times the first cost of the product. The internal revenue system became one of the most productive taxing systems of the world. The collections steadily increased and in ratio to the growth of the nation in population and wealth; and for the fiscal year ended 30 June 1914, the last under normal conditions, they amounted to $305,491,548. This was exclusive of the new income tax, for the laying of which authority had to be obtained by amendment of the Constitution. The collections from customs in the year mentioned amounted to $292,320,015 — about $13,000,000 less than the internal revenue taxes. The administration of the Internal Revenue Law is complicated and requires the employment of a large field force of inspectors, gaugers, etc., besides the office forces at Washington and in the numerous collection districts. Nevertheless, the cost of administration ordinarily does not exceed 2¼ per cent of the amount collected, which is about two-thirds of the cost of collecting the customs. The internal revenue system on all occasions has proved its adaptability to national emergencies. During the Spanish War the collections from this source were readily increased from the normal of $170,900,641, in 1898, to $273,437,161, in 1899, to $295,327,926, in 1900, and $307,180,683, in 1901. In the American fiscal system the internal revenues took the place occupied by the income tax in the calculations of British budget makers. Though the increase of internal revenue taxes is not as simple as the addition of a penny to the pound to the income tax rate, our system has been fairly elastic. It obtained its flexibility by the raising and lowering of the taxes on beer and tobacco, as occasion required, and the imposition and remission of stamp duties. The income tax has now become a permanent source of revenue for the Federal government, and this tax alone has the elasticity necessary to meet a situation in which calls for hundreds of millons are superseded by calls for billions. Notwithstanding one may discern in the newly imposed taxes on war industries, excess profits, pleasure vehicles, amusements, jewelry and dispensable luxuries, and in the stamp dues, the old concepts of the originator of the system, though enlarged to a colossal scale.

INTERNATIONAL ARBITRATION. See ARBITRATION, INTERNATIONAL.

INTERNATIONAL BOUNDARY TRIBUNAL. See ALASKAN BOUNDARY COMMISSION.

INTERNATIONAL BROTHERHOOD OF MAINTENANCE-OF-WAY EMPLOYEES, an American labor union, having a department of fraternal insurance. It was founded at Demopolis, Ala., in 1887 and in July 1914 had an American membership of 7,291 and a Canadian membership of 7,415; total 14,706. Since its organization it has disbursed more than $500,000 in death and disability benefits. It has secured increased wages for maintenance-of-way employees to the amount of $6,000,000 annually. It was actively engaged in the great strike on the Canadian Pacific Railway in 1901.

The strike was settled after a struggle lasting 11 weeks, with the understanding that all members of the brotherhood would be reinstated in their former positions within two weeks; the question of wages to be left to arbitration. Sir John A. Boyd, chief justice of Ontario, was chosen chairman of the board of arbitration and awarded the employees an increase of 20 per cent over previous wages. The brotherhood holds a charter of affiliation with the American Federation of Labor and publishes the *Advance Advocate*, a magazine devoted to the interests of maintenance-of-way employees.

INTERNATIONAL CLAIMS AND DISPUTES. The organization of the world into national states, their close interdependence and the conflicting interests arising during a war, have often led to disputes or the commission of some act or injury by a foreign government, or its citizens, against the United States. In some cases trouble has arisen between a citizen of the United States and one of a foreign country. This may take on an international character when officially recognized and prosecuted by our government. In either case claims arise which often involve a money payment. Settlement is made either through diplomatic agencies, treaties, conventions or by referring the matter to a court of arbitration.

The first important claims made by the United States against a foreign power were provided for in the treaty concluded by John Jay with Great Britain, 19 Nov. 1794. Provision was made for three arbitrations involving, first, questions relating to boundaries; second, the claims of Great Britain on account of confiscated debts; and third, the subject of neutral rights and duties. Commissions were appointed, the first giving its decision 25 Oct. 1798, declaring the river Schoodiac, under the name Saint Croix, to be the one intended as the boundary between the United States and Canada. The second commission met at Philadelphia, but came to no decision regarding the claims of British subjects as to their confiscated debts. This matter was settled later by treaty concluded 8 Jan. 1802, with an award of £600,000 to Great Britain in satisfaction of its citizens' demands. The third tribunal sat at London and decided the case of each American claimant on account of captures made under the Orders in Council, and the British claims against the United States on account of the latter's failure to enforce its neutrality. American claimants recovered $11,650,000, while the aggregate of the awards against the United States appears to have been $143,428.14. Similarly the Treaty of Ghent, 24 Dec. 1814, provided for three arbitrations between the United States and Great Britain relating to the ownership of certain islands and to boundaries.

The most famous of the claims of the United States against Great Britain was the so-called *Alabama* claims. This case was brought before the Geneva tribunal (1872). The claims were based on accusations respecting the failure of Great Britain to enforce strict neutrality during the Civil War by allowing the Confederate government to have vessels constructed in British ports; by failing to prevent their departure and seizure; and by allowing them to be fitted out as privateers, with

equipment and supplies obtained in British ports and conveyed to them in other vessels. As a result many American vessels were captured or destroyed. Great Britain at first denied that she had been guilty of any neglect. In January 1866, Secretary Seward proposed that the *Alabama* claims be submitted to arbitration, and in 1869 a convention provided for a general arbitration of the claims of the United States against Great Britain. This proposal was rejected by the Senate. Finally Secretary Fish arranged, in 1870, for the appointment of a joint high commission to settle all differences between the United States and Great Britain. Each government appointed five high commissioners, who met at Washington, 27 Feb. 1871, and after discussion signed the Treaty of Washington 8 May 1871, providing for arbitration of the *Alabama* and other claims. Great Britain apologized for the escape of the *Alabama* and other Confederate cruisers from British ports. She admitted that a neutral government was bound to use "due diligence in the performance of its duties." The claims for damages were to be submitted to five arbitrators. The United States was represented by Charles Francis Adams. The other arbitrators were appointed by the queen of England, the king of Italy, the president of the Swiss Confederation and the emperor of Brazil. The arbitrators met at Geneva and found that there had been negligence on the part of Great Britain, especially in respect to three Confederate cruisers, the *Alabama*, the *Florida* and the *Shenandoah* and awarded the United States $15,500,000.

Another dispute with Great Britain was over questions affecting the free use of the seas, involving the fur seal arbitration. The United States claimed jurisdiction over the Bering Sea, with power to protect seals outside the three-mile limit. Great Britain disputed both claims. Negotiations for arbitration led to the Convention of 29 Feb. 1892, which referred the controversy to a tribunal of seven arbitrators. This tribunal met in 1893 and decided that the United States had no property rights in fur seals outside the three-mile limit, and prescribed regulations for the protection of seals for five years, by joint action.

Other disputes with Great Britain were those of the Northeastern Boundary, settled by the Webster-Ashburton Treaty in 1842; the Alaskan Boundary, settled by a commission 20 Oct. 1903, largely in favor of the United States, and the North Atlantic Coast Fisheries, settled by The Hague Court, 7 Sept. 1910.

The United States has had several disputes with France involving principally the question of claims arising from the destruction or capture of American ships during the Napoleonic Wars. On 22 April 1793, Washington issued his proclamation of neutrality, but it was constantly violated by the fitting out of privateers, the condemnation of prizes by French consuls sitting as courts of admiralty and by the capture of vessels within the jurisdiction of the United States. The matter was complicated by the varying interpretations given to the treaty with France made in 1778, by Genet, the French Minister, and by the American government. Besides the claims arising from the destruction of vessels within the jurisdiction of the United States some of our ships were captured or destroyed on the high seas by French privateers. James Monroe was appointed Minister to France by Washington in 1794 with instructions to demand compensation for captures and spoliation of property of Americans by French cruisers. Monroe was recalled and in 1796 Charles Cotesworth Pinckney was appointed Minister with instructions to press the claims for spoliation, but the Directory then in power refused to recognize a Minister from the United States. Meantime captures, confiscations and condemnation of vessels and cargoes occurred. A special mission was appointed by President Adams in 1797 consisting of Charles Cotesworth Pinckney, John Marshall and Elbridge Gerry, who were instructed to secure a settlement of the spoliation claims, but they were unsuccessful.

Finally the mission composed of Elsworth, Davie and Murray, appointed 25 Feb. 1799, was instructed to secure compensation for all captures and condemnations of vessels contrary to the law of nations. Napoleon appointed plenipotentiaries to negotiate and a convention was signed 30 Sept. 1800, providing for a future settlement and this was finally ratified by the Senate and the French government. In connection with the treaty of 30 April 1803, ceding Louisiana to the United States, two conventions were signed, one of which provided for the settlement of the spoliation claims. Commissioners were appointed, 18 May 1803, who sat at Paris, examined the claims and made awards. This was known as the French Indemnity of 1803. The amount finally paid by France was $3,750,000.

The various decrees issued by Napoleon in retaliation for England's Orders in Council, especially those of Berlin, Milan and Rambouillet, resulted in the capture or confiscation of a large number of ships and their cargoes. The loss to Americans in consequence of the Rambouillet decree has been estimated to have been no less than $10,000,000. Between 1816 and 1829 several attempts were made by American Ministers to France to settle these spoliation claims. Finally the American Minister, Mr. William C. Rives, succeeded in persuading France to agree to the payment of 25,000,000 francs in six instalments, with interest on each from the date of the convention. Ratifications were exchanged at Washington, 2 Feb. 1832, and three commissioners were appointed by Act of Congress, 13 July 1832, to receive and examine claims. The labors of the commission proved to be very onerous and the whole period of its duration was about three years and five months. It reported, 7 June 1834, a list of claims presented, 3,148, of which 1,567 were allowed and 1,581 disallowed. Considerable difficulty and delays arose in connection with the payment of the six annual instalments by France, which led to threats by Jackson and recommendation of reprisals and finally to the breaking of diplomatic relations between the two countries. Friendly relations were restored, however, and the amount finally received from France with interest was $5,558,-108.07.

The United States has had several disputes with the South and Central American republics, most of them growing out of filibustering expeditions fitted out in the United States to aid in revolutions, Isthmian canal projects, boundary disputes and destruction of property of American citizens. An example of the first class was the effort of the Central American republics to checkmate the filibustering expeditions of William Walker, 1855–58, and their endeavors to induce the United States to take notice of his violation of neutrality laws. A second example was the dispute with Colombia over Canal Zone. A convention was negotiated 22 Jan. 1903, with Colombia, giving the United States the right to construct a canal across Panama, then a state in the Colombian Federation, together with the "use and control" of a zone of territory along the routes. For this privilege the United States was to pay $10,000,000 down and $250,000 each year, from 1913 on. Colombia failed to ratify the treaty. But four days after the Colombian Congress adjourned, a revolution occurred in Panama. American troops were landed and Colombian troops were prevented from landing. A few days later, 6 November, the United States recognized the Republic of Panama. On 18 Nov. 1903, a similar treaty was negotiated with Panama, recognizing the United States "as the sovereign over the territory" in question, a strip across the Isthmus 10 miles wide. By a treaty made January 1909, between Colombia and Panama and Panama and the United States, the latter granted Colombia $250,000 a year which had originally been agreed upon in return for the rights granted in connection with the Panama Canal.

The United States has also been drawn into disputes with foreign countries involving South and Central American republics, because of the Monroe Doctrine; for example, the dispute between Great Britain and Venezuela respecting the boundary of British Guiana. President Cleveland in 1895 insisted that under the Monroe Doctrine it was the duty of the United States to see that Great Britain did not take any Venezuelan territory that she was not entitled to. Venezuela appealed to the United States and the latter offered its services as arbitrator. Great Britain at first refused either to recognize the right of the United States to be heard or to submit the question to arbitration, but under pressure agreed to arbitrate, and in February 1897, an agreement was reached which granted to Great Britain most of the territory in dispute.

Claims of American citizens or corporations have frequently been made against South American republics, because of confiscation or destruction of property, especially in time of civil war.

A dispute with Italy arose, 15 March 1891, out of the shooting by a mob of several Italians in jail at New Orleans. They were awaiting trial for the murder of Mayor Hennessey, who had been investigating the operation of the Mafiosi, a famous secret society. The Italian government demanded punishment and indemnity, though jurisdiction was with the State of Louisiana and recalled her Ambassador. Finally in 1892 the United States voluntarily paid an indemnity of $24,000 to Italy and friendly relations were restored.

INTERNATIONAL DATE LINE. The imaginary line at which dates change, being made later by one day by those who cross the line from east to west and earlier by one day by those crossing it from west to east. It is a somewhat irregular line drawn through the Pacific Ocean in a general northerly and southerly direction and separating the islands of the Pacific Ocean in such a manner that all those lying to the east of it carry the same date as the United States, while all those on the west of it carry the same date as Japan and Australia. If a person start at midday, that is, when the sun was shining perpendicularly on the meridian that passes through the place of starting, and travel westward, keeping pace with the sun, thus keeping the sun directly over the meridian of the place at which he might be, he would make a complete journey around the globe in twenty-four hours and return to his place of starting at noon the next day. Twenty-four hours would have passed, but to the traveler the sun would have been shining perpendicularly as at noon all the time; and the question arises, when or at what point did the traveler change from noon of one day to noon of the next? For instance, if he should start at Monday noon and keep the sun in the zenith, he would arrive at the place of starting Tuesday noon — it would be noon-day to him during the whole journey of 24 hours. Monday noon would change to Tuesday noon without an intervening night; where would the change occur? It is to him apparently still Monday noon and to obtain the correct date he must drop a day. The reason for dropping a day can be more fully shown as follows: Remembering that the earth makes one complete revolution on its axis in 24 hours and thus the sun in its apparent diurnal revolution moves over 360 degrees of space in 24 hours, it thus moves over 15 degrees of space in one hour, from which it is evident that the difference in longitude which causes the difference in the relative time, may be estimated in time, allow-

ing 15 degrees to an hour, or one degree to four minutes. Therefore, suppose a man starting from any given point travel one degree west, his watch, instead of marking 12 o'clock at noon, according to the correct time at that place, would mark four minutes after 12. Let him travel west 15 degrees, and he will find that one o'clock by his watch will be noonday by the sun. Let him go on to 120 degrees and when the sun is in the zenith his watch will indicate eight o'clock P.M. Completing his journey around the globe, he will have gained, in this manner, 24 hours. From this it will be seen that in order to obtain the correct date 24 hours must be subtracted from his time. On the other hand if a person could travel eastward at the same speed with which the sun apparently travels westward (the same rate of speed with which the earth revolves on its axis), if he should start on his journey at noonday, he would meet the sun when exactly on the opposite side of the earth from the place of starting and continuing the journey would again meet the sun at the place of starting, thus seeing three noondays within the 24 hours, or apparently gaining a day. This we know to be impossible, since only 24 hours of time have passed, while in reality an extra period of light has been gained and thus to obtain the correct local date a day must be added to your time. From this we see that, for every time a person travels around the earth in either direction there is a difference in time of one day and the result is the same regardless of the rate of speed. To avoid the confusion of dates which must necessarily result from this constant gain on one side and loss on the other, it has been proposed to determine upon some line at which eastern bound travelers shall add one day and westward bound travelers shall drop a day from their reckoning and thus prevent a disagreement in regard to the day of the week. The line at which this addition or subtraction shall be made is what is meant by the date line.

The dates in use upon most of the Pacific Islands and groups of islands are those which result from those carried by the first European or American colonists, these dates differing according as the colonists came from the east or the west. But, this is not time universally, because arbitrary changes are known to have been made in a number of cases, such as Alaska, the Philippines, etc. When Alaska was first colonized by the Russians it had the Russian date. When American settlers moved there, they carried with them the date of the United States which led to considerable confusion, the Sunday of the Americans being the Monday of the Russians. In 1867, when the United States purchased Alaska from Russia, the date in use there was made to conform to that used in the United States.

INTERNATIONAL INSTITUTE OF AGRICULTURE, a world organization, with headquarters in Rome, Italy, founded in 1905, and having for object the collection and dissemination of knowledge relating to agriculture in the various countries represented in the institute. In 1904 the idea of such an institute came to Mr. David Lubin (q.v.) of Sacramento, Cal., and his project found favor with the king of Italy. The latter gave a building in Rome and an annual income of $60,000. The king called the first congress in 1905, and delegates attended from 40 countries. At the congress a treaty was formed making the institute a permanent organization and defining its scope and activities. The government of the institute is vested in the general assembly of delegates from affiliated countries, meeting every two years, and in a permanent executive committee, on which there is one representative from each country. This permanent committee has direct charge of the institute. The general officers are the president, who is also chairman of the permanent committee; the vice-president and the secretary-general. The work of the institute is divided among four bureaus: (1) The bureau of the secretary-general; (2) the bureau of general statistics; (3) the bureau of agricultural intelligence and plant diseases, and (4) the bureau of economic and social institutions. The bureau of the secretary-general has charge of the personnel, financial and other routine business, the building and its equipment, the printing and distribution of publications, the library and general bibliographical work, and, as a more recent service, the preparation and publication of an annual compilation of agricultural legislation in the different countries of the world. The bureau of general statistics collects, collates and publishes statistics of production and commerce in agricultural products, both animal and vegetable, throughout the world. The bureau of agricultural intelligence and plant diseases collects and publishes information regarding the progress of scientific and experimental investigations and practical experience in agriculture throughout the world and, as a branch of this work, gives special attention to the diseases of plants and to entomology. The bureau of economic and social institutions collects and publishes statistics and general information regarding agricultural cooperation, insurance and credit, together with other matters relating to the economic and social organization of rural communities.

Those publications of the institute which have a bearing on the formation of the price of the staples (such as crop reports and data on exports, imports and stocks) are based exclusively on official information, supplied direct to the institute by the adhering governments. The other publications are produced from the following sources: (a) Information officially communicated by the governments; (b) original articles contributed by eminent authorities designated by the adhering governments; (c) excerpts and abstracts of articles translated from the 2,225 official and unofficial periodical publications of the world received by the institute.

The institute prints and publishes two annuals and three monthly and one weekly bulletins, together with a considerable number of monographs on special subjects. The annuals deal with agricultural statistics and legislation, respectively; the monthly bulletins are on (1) agricultural statistics; (2) agricultural intelligence and diseases of plants, and (3) economic and social institutions, and the weekly bulletin is bibliographical. The monthly bulletins are published in French, German, English, Spanish, Italian and Hungarian. French being the official language of the institute, the editions in that language are paid for from the funds of the institute. Provision for the edition in the other languages is made by the countries

interested. The Congress of the United States has made an annual appropriation of $5,000 for translating and printing the English edition, the rest of the expense being borne by Great Britain and her colonies. The institute has collected a great library of the world's best in agricultural literature. As the institute becomes more firmly established and its value as an international clearing-house on economic information is more generally recognized it is met with a constantly increasing demand for the extension of its service along the many lines included in the broad movement of our day for agricultural advancement. The annual budget of the institute is now $250,000, contributed by the adhering governments, on the basis of units; thus the contribution of the United States is on the basis of 16 units. Consult 'Senate Document No. 196, 63d Congress, First Session' (Washington 1913), from which the preceding account has been compiled, and 'L'Institut International d'Agriculture' (Rome 1912).

INTERNATIONAL JOINT COMMISSION. See LAKE-TO-SEA COMMISSION.

INTERNATIONAL LANGUAGE, general term applied in modern times to artificial languages designed for facilitating intercourse between peoples whose national languages or mother speeches differ one from the other. These artificial languages aim toward facility of acquirement through general rules which admit of no exception although some are little less complicated than English for example. In this encyclopedia the principal artificial languages are treated under their own headings, as Soldrisol, Esperanto, Volapük, Ro, etc. (qq.v.).

INTERNATIONAL LAW. In the judgment on appeal in the case of the *Zamora* the judicial committee of the English Privy Council said on 7 April 1916, that "A court which administered international law must ascertain and give effect to a law which was not laid down by any particular state, but originated in the practice and usage long observed by civilized nations in their relations with each other or in express international agreement." Practice and usage and international agreement are main sources of international law.

The statement that international law is not law is sometimes made on the ground that international law is not laid down by a sovereign state. It is nevertheless recognized as law by the highest courts of sovereign states. Such recognition is found not merely in recent but in early decisions. Lord Mansfield of England, in 1761, quotes Lord Talbot who says, "That the law of nations, in its full extent, was a part of the law of England." "That the law of nations was to be collected from the practise of different nations, and the authority of writers." (Triquet v. Bath, Burrage, reports, 1478). Lord Russell of Killowen, the Lord Chief Justice of England, in 1896 defined international law as "The sum of the rules accepted by civilized states as determining their conduct toward each other, and toward each other's subjects." Later in 1905 Lord Alverstone, the Lord Chief Justice, in the case of the West Rand Central Gold Mining Company said, "It is quite true that whatever has received the common assent of civilized nations must have received the assent of our country, and that to which we have assented along with other nations in general may be called international law, and as such will be acknowledged and applied by our national tribunals when legitimate occasion arises for these tribunals to decide questions to which doctrines of international law may be relevant." What is true of other states is true of the United States. In 1796 Mr. Justice Wilson of the Supreme Court said, in the case of Ware against Hylton, "When the United States declared their independence, they were bound to receive the law of nations, in its modern state of purity and refinement." In 1900, in the case of the *Paquete Habana,* following in this respect the case of Hilton v. Guyot of 1894, the Supreme Court of the United States said, "International law is a part of our law, and must be ascertained and administered by the courts of justice of appropriate jurisdiction, as often as questions of right depending upon it are duly presented for determination." It must be granted, therefore, that for the courts there exists international law and that this has been recognized for many years and is still recognized.

Naturally international law did not develop till the political entities called states had become fairly well established, as states are necessary parties to international relations. Evidences of some practices which have later received the sanction of international law are found in very early records of the countries of the East. As relations of states became closer, through the spread of commerce and the intercourse developed by the Mediterranean civilization, laws upon matters of common interest were accepted as necessary for the continuance of relations which were regarded as advantageous. In these early laws there was little of what might be called regard for theoretical rights of states. These laws usually grew out of the recognition of practical advantages in a certain line of conduct toward other states. As Rome became dominant there appeared in the law about the Mediterranean a unity due to the concentration of power at a single seat of government. This certainly furnished an example of the possibility of a degree of unity of law for different peoples. This law particularly reached to the relations of individuals in selling, buying, travel, etc. Under Roman jurists theoretical concepts gained influence. *Jus gentium* and *jus naturale* were expounded. The latter as embodying the law in harmony with the fundamental principles of existence had large influence upon the development of the theory of international law in later days and many books combined in their titles the law of nature with the law of nations.

Before Grotius (1583–1645) there were many who wrote upon matters relating to international affairs. Among these are the well-known names of Victoria (1480–1575), Ayala (1548–84), Suarez (1548–1617) and Gentilis (1552–1608). The great work of Grotius, 'De jure belli ac pacis' (1625), formulated and clarified much of what is now called international law. From this foundation Grotius gained the title of Father of International Law. His work influenced the leaders in international affairs almost immediately and the Treaty of Westphalia at the end of the Thirty Years War, 1648, embodied ideas of this great master. To

Grotius all writers acknowledged their indebtedness.

From the days of Grotius different schools began to develop. One school, sometimes called the «naturalists,» particularly followed the natural law theories, theories in their harmony or agreement with the inherent forces of the universe. Another school, the «Positivists» looked particularly to customs and treaties for the sources of international law. Aside from those who were commentators upon the work of Grotius, the main contributions were from writers upon special topics, such as the writings of Bynkersholk (1673–1743). The systematic work of Vattel (1714–67) had wide circulation in Europe and in America as did that of the American, Henry Wheaton (1785–1848). With the increase in the number of court decisions involving principles of international law, there has arisen a clearer definition of the field of international law and a recognition of its binding character.

Treaties, particularly since the Treaty of Westphalia of 1648, have embodied international law. Where the same clause occurs in a large number of treaties or when a large number of states are parties to one treaty the principle or principles tend to be generally accepted as law. Such was the case in regard to some parts of the Treaty of Utrecht of 1713 which were repeated in other treaties of the 18th century. The doctrine of the balance of power in Europe as a basis of peace clearly set forth in this treaty was accepted as a fundamental principle in the diplomatic negotiations in Europe for many years. According to Talleyrand a hundred years later in 1813 the balance of power was «a combination of the neutral rights and interests of the Powers, by means of which, Europe aims at securing the following objects:

«1. That no single Power, nor any union of Powers shall have mastery in Europe.

«2. That no single Power nor union of Powers shall be able to infringe the actual possession and recognized rights of any other Power.

«3. That it shall no longer be necessary, in order to maintain the established state of affairs, to live in a state of imminent or actual war, and that the proposed combination shall secure the peace and repose of Europe against the efforts of a disturber by diminishing his chances of success.»

If all that had at times been hoped for from the acceptance of this doctrine of balance of power had been realized, law in international relations would have developed much more rapidly.

Another principle that has been embodied in many treaties following the Treaty of Utrecht was in its brief form «free ships make free goods» and there was also coupled with it the principle that «enemy ships make enemy goods.» This was a step in advance of earlier practice, particularly of the 17th century, which did not acknowledge that innocent enemy goods under a neutral flag were free from capture. A hundred years later Napoleon claimed that these doctrines of the Treaty of Utrecht had «become through their adoption in subsequent treaties, the common law of nations.»

Progress has, however, been made in international law as in other law and in general there has been a tendency to free commerce from restraints. In respect to the treatment of goods upon the sea, the United States which had in the late 18th century but recently come into the family of nations as the first member from outside of Europe, endeavored to obtain complete exemption from capture of innocent private property even if belonging to enemy persons. In the last quarter of the 18th century the principle was even embodied in certain treaties made by the United States, but it did not receive general approval.

While the precedents of the long negotiations leading to the Treaty of Westphalia of 1648 established some clear lines of diplomatic practice, there were many points upon which disputes were common. The disputes sometimes led to personal encounters. As the diplomatic agent was regarded as embodying in the foreign state the dignity of the state which he represented, he endeavored to obtain for himself the place of greatest prominence. He strove for the highest place at the table, the chair at the right of the sovereign on ceremonial occasions, and by fair means or foul to gain precedence. Bribery of officials was common and some of the books of the early 18th century explain the principles of its use. The rivalry of states became at length so keen that it seemed desirable to lay down laws for the precedence of diplomatic agents. The Congress of Vienna of 1815 embodied a conventional agreement which with an addition at the Congress of Aix-la-Chapelle in 1818 made the grade of diplomatic representatives as follows:

1. Ambassadors, legates and nuncios.
2. Envoys and ministers.
3. Ministers resident.
4. Chargés-d'affaires.

This fixing of the grades removed friction that had long existed, as states were expected to exchange representatives of equal rank. The United States did not, however, send abroad agents of the grade of ambassadors till after the Act of Congress of 1 March 1893, authorizing such action on the part of the President.

As freedom of action was essential for the performance of the functions of the diplomatic agent, the principle of inviolability was extended not merely to the person of the diplomat but to his suite, family and hotel or official residence with all the personnel and equipment which might be necessary or reasonably convenient for the proper performance of his functions. He was also entitled to certain honors, such as salutes according to his grade. His prerogatives, if an ambassador, extended to the right to ride in a coach with six horses and outriders and to remain covered in the presence of the sovereign if the sovereign did not remove his hat. Other grades were entitled to lesser marks of respect. The establishing of these rules removed the causes of the ancient contests over rank and dignities and enabled the diplomatic agents to live in harmony and transact the business of the state, receiving the honors not as personal but as for the states which they represented. Each state in sending its representative and in determining his grade determined his rank at the court to which he was accredited. Minor differences have arisen, but for the most part the controversies as to rank which were common before 1815 have come to an end.

Other problems which were once perplexing in international relations, as for instance, the regulation and later the suppression of the slave trade have likewise disappeared.

Some have taken new form as the use of private vessels in the time of war after the abolition of privateering, and new problems have arisen, as in the regulation of the use of the air. To meet these changes the international law development of the 19th and 20th centuries has tended to become more and more conventional.

The conventional international agreements were at first generally incidental to some other international act as in the agreement fixing the grades of diplomatic agents. The same was true of the Declaration of Paris of 1856 in which it was stated that the plenipotentiaries who signed the Treaty of Paris «considering that maritime law had long been the subject of deplorable disputes . . . cannot better respond to the intentions by which their governments are animated, than by seeking to introduce into international relations fixed principles, in this respect.» They accordingly made «the following solemn declaration:

"1. Privateering is and remains abolished:
"2. The neutral flag covers enemy's goods, with the exception of contraband of war:
"3. Neutral goods, with the exception of contraband of war, are not liable to capture under the enemy's flag.
"4. Blockades, in order to be binding, must be effective — that is to say, must be maintained by force sufficient really to prevent access to the coast of the enemy."

The United States and several other powers did not adhere to this declaration, though its principles were generally recognized. The United States wished in 1856, as in earlier and later days, to secure the general exemption from capture of private property at sea.

Agreements reached by states assembled for the purpose of formulating what may be called international law gradually became common. It would seem but natural that the destruction of life without advantage to any state would be one of the early matters of attention as a subject for a formulated international agreement. Yet the first international agreement relating to this matter to receive general assent was concluded in 1864, and known as the Geneva Convention for the Amelioration of the Condition of Wounded in Armies in the Field. The representatives of 12 European states stated in the preamble their purpose to be to mitigate «the evils inseparable from war, to suppress useless severities, and to ameliorate the condition of soldiers wounded on the field of battle.» It was a long time for the world to wait for such legislation. This Geneva Convention of 1864, which provided for the immunity of the hospital corps, was not immediately ratified, however. The United States did not adhere to this convention till 1882, and this was the only international agreement of general scope and relating to war to which even the United States became a party before the end of the 19th century.

The Conference of Saint Petersburg followed in 1868 and was attended by representatives from 17 European states, and these agreed upon the Declaration of Saint Petersburg, which denounced among the signatories «the employment by their military or naval troops of any projectile of a weight below 400 grammes, which is either explosive or charged with fulminating or inflammable substances.»

The Geneva Convention of 1864 and the Declaration of Saint Petersburg of 1868 related particularly to a state of war. Soon other matter became increasingly the subject of international conferences, and before the end of the 19th century, general conventional agreements had been made and signed by a large number of states acting together upon such matters as an «International Bureau of Weights and Measures» (Metric System), 1875; «International Protection of Industrial Property,» 1883; «Protection of Submarine Cables» (in time of peace), 1884; «Exchange of Official Documents, Scientific and Literary Publications,» 1886; «Repression of African Slave Trade,» 1890; «Formation of an International Union for the Publication of Customs Tariff,» 1890; and «Regulations of Importation of Spirituous Liquors into Certain Regions of Africa,» 1899. Such international agreements became a part of the written law of nations, but covered only a very small part of the entire field of international relations in peace and war.

There was developing toward the end of the 19th century a belief that by agreement among the states of the world a basis of conventional law could be reached which would do much to alleviate possible friction and even to avoid war. The extent to which this belief was realizable was to be put to the test. While the United States and Spain were still at war, at the diplomatic reception of 12 Aug. 1898, at Saint Petersburg, Count Mouravieff, Russian Imperial Minister of Foreign Affairs, delivered to the representatives of the Powers a communication from His Majesty the Czar. While the nature of the document gave rise to surprise, its character and source demanded immediate attention. Mentioning the competition in development of means of international combat and the effect of this competition upon the states of the world, he proposed an international conference, saying that:

"To put an end to these increasing armaments, and to find means for avoiding the calamities which menace the entire world, that is the supreme duty which lies upon all nations."

The United States replied that:

"Though war with Spain renders it impracticable for us to consider the present reduction of our armaments, which even now are doubtless far below the measure which principal European powers would be willing to adopt, the President cordially concurs in the spirit of the proposal of His Imperial Majesty."

On 11 Jan. 1899 another circular was presented to the Powers containing a tentative program. This program suggested agreement upon (1) limitation of armaments; (2) restrictions upon new methods of warfare; (3) prohibition of firing from balloons; (4) prohibition of submarines and rams; (5) adaptation of principles of Geneva Convention of 1864 to naval warfare; (6) neutralization for vessels saving those overboard after battles at sea; (7) revision of rules of war on land; and (8) acceptance of principles of mediation and arbitration with a view to preventing armed conflicts. Of these eight topics suggested, seven look to furthering peace by limitations upon the conduct of war, and the last topic suggests a quasi-legal method of furthering the movement toward peace.

Following the suggestion of the Czar, repre-

sentatives of 26 Powers met on 20 May 1899, in the House in the Wood at The Hague, and remained in session a little more than two months. This is known as the First Hague Peace Conference. The Conference drew up three conventions, three declarations, one resolution, and six wishes: Conventions: (1) for the pacific settlement of international disputes by means of good offices and mediation, commissions of inquiry and arbitration; (2) regarding the laws and customs of war on land; (3) adaptation of Geneva Convention of 1864 to maritime warfare. Declarations: (1) prohibiting the discharge of projectiles from balloons; (2) the use of projectiles for the diffusion of deleterious or asphyxiating gases; (3) the use of expanding bullets. Resolution affirming the desirability of the restriction of military budgets. Wishes for further consideration of various matters upon which the Conference had not reached agreement. The last topic upon the program suggested by the Czar had become the first convention of the First Hague Conference, or the furtherance of the aim of peace by means quasi-legal in character assumed a foremost place in the results of these deliberations at The Hague; and the first item in the program, the attainment of international peace through the restriction of the means by which each nation had hitherto maintained its rights, viz., effective armament, became the subject of a resolution and a wish. The Conference asserted its confidence in the law as the method for settling international disputes.

Following this conference of 1899 there was a wider interest in the possibility of law for the world. While the Russo-Japanese War of 1904–05 was still in progress, a request was made by those interested that President Roosevelt call another conference. He had already taken the first steps toward such action when advised that the Czar of Russia desired to call the conference and at the close of the Russo-Japanese war the Czar carried out the plan. It was now fully admitted that the work of the First Hague Conference of 1899 had been of great value for the world.

Eight years later, in 1907, a Second Hague Conference further elaborated and formulated conventional agreements, and to this Conference representatives of 44 of the states of the world came, giving ample evidence of the tendency to accept the principle of international legislation. Some of the conventional agreements have been tested in the course of years. The court established for the settlement of international disputes attained a recognized standing. Cases affecting all parts of the world have already been decided and the awards accepted. The Second Hague Conference extended the scope of the law. Among its propositions which have not been adopted as yet into the law of nations was that to establish an international prize court. This proposition was generally approved in principle though a satisfactory method of selection of judges was not devised. To supplement this prize court convention an attempt was made by 10 maritime nations in 1908–09 at the International Naval Conference at London to formulate the laws which the court should apply. The Declaration of London of 1909 embodied the labors of this Conference. This Declaration has not been ratified. It is not merely in these broad national matters that the formulation of the law has progressed, but in recent years many such matters as the following have become subject of general international agreements: literary and artistic copyrights, 1902; sanitary measures, 1903; white slavery, 1904; potent drugs, 1906.

Rights, persons and property, and jurisdiction on land and sea earlier had received attention; in more recent years the use of the air has been the subject of international regulation, as in the conventions of 1906 and 1912. To the last of these conventions the representatives of about 40 non-American political unities affixed their signatures, many of the larger states allowing here, as in some other conventions, participation in the formulation of the law to the divisions of which the state entity was composed. The legislation thus rested upon a broader base than in many conventions of earlier years.

In the application of the law for nations the progress has been exceedingly rapid. Cases which have defied the best efforts of diplomacy for generations, as the North Atlantic Fisheries dispute, have been settled by due process of law in a few weeks. Cases which might have resulted in long and disastrous international contention have been resolved in the light of law. Where recourse to legal settlement of disputes was in earlier times the last resort, it has become the first, and not merely the parties to the controversy may begin the action, but third parties may of right suggest or even try to bring the parties to submit the case to the decision of the court.

It requires only a review of the conventions since 1899 to show how rapid is the formulation of the law for nations. These international laws, in addition to many private matters, cover the pacific settlement of international disputes, limitation of the employment of force in the collection of contract debts, laws for war on land, rights and duties of neutral powers and persons in war on land, status of enemy merchant ships at the outbreak of hostilities, the transformation of merchant ships into warships, the laying of automatic contact submarine mines, bombardment by naval forces in time of war, care of sick and wounded in time of war, rights and duties of hospital ships, exercise of right of capture in maritime war, prohibition of discharge of projectiles from balloons, rights and duties of neutral powers in time of war, the establishment of an international prize court and the law for its guidance.

Not merely had the law developed and become somewhat widely the subject of formal international acceptance, but many of the conventions embodying the law had been put to severe tests. Probably few more serious tests could be imagined than that which one part of the convention for the Pacific Settlement of International Disputes received in 1904 during the Russo-Japanese War. In this convention there had been placed a section providing for a sort of international grand jury called a Commission of Inquiry to investigate the facts in case of a dispute between nations when agreement to resort to such a procedure could be reached. On the night of 21 Oct. 1904, a division of the Russian fleet under Admiral Rozhdestvensky, on its way from the Baltic Sea to the Far East, while passing through the

North Sea near the Dogger Banks, fired on the British fishing fleet. The fishermen suffered the loss of one trawler, five were damaged and two men were killed and six wounded. Great Britain was an ally of Japan and the sympathy in the British Isles was generally with the Japanese. When the news of this disaster spread the demand for action was urgent upon the British government. Orders were issued by the Admiralty to the Mediterranean, Channel and Home fleets, and the British Foreign Office announced on the 25th of October that it had made known to Russia "that the situation is one which in the opinion of His Majesty's Government does not admit of delay." The same day the Czar in a message to the king said "he would take steps to afford complete satisfaction as soon as the circumstances of the case were cleared up." On the following day the Russian fleet arrived at Vigo and reported that the reason for the firing was the presence of Japanese torpedo boats among the fishing vessels. This the fishermen denied. The demand in England for war had a little time to subside and fortunately the method for honorable submission of such a dispute existed in the Convention of 1899, to which Great Britain and Russia were parties, and it was agreed to submit the dispute to a Commission of Inquiry. The commission was composed of admirals from the American, Austrian, French, British and Russian navies. The report of the commissioners was adverse to the Russian contentions and the incident was closed by the immediate payment of £65,000 to Great Britain. Thus a dispute which might have been regarded as an ample cause for war was by peaceful methods settled promptly and honorably.

This provision for commissions of inquiry was elaborated in 1907, that it might, if occasion arose, become even more serviceable.

Another Convention of 1899 prohibited the discharge of projectiles or explosives from balloons for a period of five years. While this period expired during the Russo-Japanese War, both Russia and Japan continued to observe the spirit of the prohibition.

The rules for war on land were also tested and further changes were found necessary in 1907.

Not merely was there made in 1899 provision for a commission of inquiry but also for a court of arbitration. It was thought for a time that this court would never perform any function. It remained for two American republics to first test the court of arbitration, for which provision had been made in the Convention of 1899. In 1902 the United States and Mexico took before the court its first case.

This was the case of the Pious Fund of the Californias, which had been in dispute from the annexation of Upper California in 1848 by the United States. An arbitral award in 1875 had granted to the United States claimants 21 years' interest on one-half the Fund which had originally been given to the missionaries for their work in the Californias. The interest for subsequent years had not been paid and it was claimed by the Catholic Church of California. The contention of the United States was upheld by the court and the protracted dispute was at an end.

Other cases came to The Hague court after this first award and it soon became customary for states to request that in case of dispute "the matter be referred to The Hague."

The next case related to the preferential treatment for the powers which had blockaded Venezuelan ports in order to enforce the payment of debts due their citizens. Here not two but ten states were involved, representing Europe, North America and South America. This case was quickly followed by one in which Germany, Great Britain and France appeared against Japan in the matter of the perpetual leases in that country, thus introducing Asia also before the court. Another case involving Asiatic interests was the case of the right of the Muscat Dhows to fly the French flag, which was a subject of difference between Great Britain and France.

These four cases were before the court at The Hague between 1902 and 1905. In 1907, at the Second Hague Conference, the convention relating to the court was amended and extended to meet the needs which experience had demonstrated.

The first case under the revised convention was settled in 1909, the Casabianca case, which had brought France and Germany to the verge of war. The same year the controversy over the maritime boundary between Norway and Sweden was adjusted.

In 1910 the court attempted to settle the dispute between the United States and Great Britain over the North Atlantic Fisheries. This dispute had continued in varying forms for about 100 years. Diplomatic negotiations had failed many times. Within a few weeks a decision accepted by both parties was reached by the court.

Questions of national honor and fundamental rights were considered in such cases as the case of Savarkar in 1910, the case of the *Manouba* and of the *Carthage* in 1913, and various aspects of financial claims in those of the Orinoco Steamship Company in 1910 and the interest on Russian indemnities in 1912. In June 1914 The Hague Court made an award settling the land boundaries in the island of Timor.

The range of cases settled by the court is accordingly very wide. The frequency of resort to the court was rapidly increasing. Interests involving the Americas, Europe, Asia, Africa and the area near Australia had been considered. Seventeen of the 44 states represented at the Second Hague Conference had appeared at least once and some six times before the court at The Hague. The awards of the court had in every instance been accepted in good faith and observed.

Such progress in the substitution of law for other means of settling disputes was a marked evidence of the advance of the early 20th century. While other methods may for a time be tried, the decision in the case of the *Zamora* before the judicial committee of the English Privy Council on 7 April 1916, seems to show that the only sound basis for international relations is in respect for international law. See ARBITRATION, INTERNATIONAL; ARMED NEUTRALITY; BLOCKADE; DECLARATION OF LONDON; DECLARATION OF WAR; MERCHANT VESSELS, NEUTRAL, RIGHTS OF; NEUTRALITY.

GEORGE GRAFTON WILSON,
Professor of International Law, Harvard University.

INTERNATIONAL LAW, Changes in. During the 50 years preceding the outbreak of the European War in 1914, international law, which originally consisted of a more or less indefinite mass of custom, usage and opinion, underwent a remarkable development. Much of that which was unwritten and uncertain was reduced to writing, embodied in conventions and given the character of definiteness and precision. Many new rules dealing with matters hitherto unregulated by custom were also elaborated and embodied in international treaties and conventions. The Declaration of Paris (1856) and of Saint Petersburg (1868), the Geneva Conventions of 1864 and 1906, the 16 conventions of the two Hague Conferences of 1899 and 1907 and the unratified Declaration of London of 1909, constituted a great body of written law, embodying not all, but the larger portion of the rules of conduct observed by states in their relations with one another, both in war and in peace.

At the outbreak of the European War, the most important of these international acts, the conventions of the Second Hague Conference, had been ratified by all the important powers of the world, although in some instances certain states had reserved their ratification of particular articles. Several of the conventions, however, contained a stipulation that their provisions should not apply in time of war, except between the contracting parties, and then only when all the belligerents were parties thereto. Among the belligerents in the recent European War, Bulgaria, Italy, Montenegro, Serbia and Turkey have not ratified the conventions, in consequence of which they were not legally binding on any of the powers involved in the war. There was a general feeling, however, that the failure of a few states, most of which were petty powers, to ratify the conventions should not be allowed to defeat their purpose, and it does not appear that any belligerent took advantage of the fact that the conventions were not legally binding upon it to avoid the obligations which they created. Thus the British prize court has uniformly taken the position that although it was not legally bound by the terms of The Hague Conventions for the reasons mentioned above, it would nevertheless act as if they were binding, and would therefore in dealing with the claims of German subjects accord them the benefit of any convention which Germany had ratified.

While happily there was no disposition among the belligerents to take advantage of the circumstance that The Hague Conventions were not technically binding to escape the obligations which they impose, many of the provisions of the conventions, to say nothing of customary rules which had become firmly established, were disregarded on the pretext of military necessity or on the theory that the changed conditions of warfare and the introduction of new methods and agencies had rendered them obsolete or made conformity to their prescriptions no longer obligatory. The deliberate violation of the neutrality of Belgium by Germany and the characterization of the Belgian neutrality treaty as a "scrap of paper" was soon followed by various other acts which created the impression that Germany proposed to disregard every rule of international law which stood in the way of her military success. Other belligerents refused to be bound by certain rules of international law on the theory that the obligation to conform to its prescriptions are reciprocal, and consequently the refusal of one to observe the law released its adversaries from the duty of obedience. Still other violations were defended on the alleged right of retaliation. So numerous were the instances of non-conformity to The Hague Conventions as well as the unwritten usages and practices of the past that many persons publicly asserted that the whole body of international law had broken down if it had not actually ceased to exist. It is true that the period of the war was a crisis for international law; never before had it been subjected to so severe a test, but in a war of such gigantic proportions, characterized by the most extreme bitterness, and conducted largely according to new methods and with new agencies, it was inevitable that many rules formulated for the conduct of war under widely different conditions should have been disregarded if not repudiated outright by the belligerents. Nevertheless, this constituted no valid ground for holding that the whole fabric of international law had collapsed any more than arguing that a breakdown in the administration of a criminal law involves the subversion of the entire criminal code. While all the belligerents undoubtedly contravened certain of the well-established rules of international law during the European War, the most flagrant violations were committed by a single power, and not even it went so far as to repudiate those rules or deny their existence. Their existence was indeed readily admitted, but their binding effect was denied on grounds of military necessity, changed conditions or the alleged refusal of the enemy to conform to their prescriptions. The great body of international law, therefore, although strained and disregarded in many instances, still remains intact, and no belligerent has ever proposed that it be thrown overboard and war conducted without regard to the established conventions and usages. As Mr. Coleman Phillipson, a well-known English writer, well says: "International Law has not been destroyed. Despite the numerous breaches we need not despair of its future. Its inherent vitality will never, and never can be entirely destroyed. Notwithstanding the many wounds inflicted upon it, it will rise again helped and invigorated and will assume its inalienable dominion over the society of states. Its rules rest upon the permanent necessities of intercourse between nations." Indeed, there is good ground for believing that one of the results of the tremendous conflict which has so rudely shaken the structure will be an infusion of new life and strength into its body. Speaking on this point before the American Society of International Law in March 1916, ex-Senator Elihu Root said:

"Vague and uncertain as the future must be, there is some reason to think that after the terrible experience through which civilization is passing there will be a tendency to strengthen rather than abandon the law of nations. Whatever the result may be, the world will have received a dreadful lesson of the evils of war. The sacrifice of millions of lives, millions homeless and in poverty, industry and commerce destroyed, overwhelming national debts,—all will naturally produce a strong desire to do something that will prevent the same thing happening again."

Mr. Root added that the return of peace will find us living in a different world. "Universal mourning for the untimely dead, suffering and sacrifice, the triumph of patriotism over selfishness, the long dominance of deep and serious feeling, the purifying influences of self-devotion, will surely have changed the hearts of the nations, and much that is wise and noble and for the good of humanity may be possible that never was possible before."

Under these conditions may we not expect, instead of a desire to repudiate a system by which differences may be settled peaceably or to throw overboard the body of law by which the rights and obligations of nations are defined and guaranteed, that a more widely diffused and strengthened sentiment in favor of a more effective and enforceable body of law will be created throughout the world?

Although it may be confidently assumed that the great body of international law will emerge from the welter and chaos of the war in the main intact, it is true that the war has revealed in a striking manner some of its inherent weaknesses and deficiencies, as no preceding conflict ever did. It has been shown that "a decent respect for the opinions of mankind" and the obloquy which comes from nonconformity to the established rules, in short the desire of belligerents to have the approval of the public opinion of the civilized world, is not yet an effective sanction of international law. It has been shown that the rules of international law like the rules of municipal law must have sanctions behind them, that is, their violations must be followed by punishment. There must be some power stronger than the violator which is capable of bringing him to book and of punishing him for his unlawful acts. Article 3 of Convention IV of the Second Hague Conference undertakes to fix a responsibility for the violation of the rules laid down by the convention. It declares that "the belligerent party who violates the provisions of the said *réglement* shall be held to make an idemnity, if there is a place for it" and that "he shall be held responsible for all acts committed by persons constituting a part of his armed force."

Unfortunately, however, the convention provides no machinery or indicates no method of enforcing the responsibility thus proclaimed. If, therefore, the purposes and objects of international law are to be fully realized, some means of enforcing its prescriptions and of compelling states to fulfil the obligations which it imposes must be found. What under the strain of a world-wide conflict has proved to be little more than a code of etiquette must be transformed into a body of real law, violations of which by particular states may be effectively punished. This is the great task to which publicists and international jurists will have to turn their attention after the close of the war if international law is to be strengthened and made to fulfil its purposes.

One proposal that has been widely discussed since the outbreak of the war is the organization of a league of states to enforce the preservation of peace and the observance of international obligations. This proposal contemplates a resort to commercial boycotts, non-intercourse measures and possibly the application of force against a state which commits a breach of the peace, commits an aggression against a member of the league, or otherwise violates its international duties. It is quite true that there have been instances in which a combined policy of non-intercourse against a powerful state would have deterred it from making an unjust attack against another power or from disregarding its international obligations, but there have been other instances when it would have probably proved ineffective. The application of force against a delinquent state is an even more extreme measure. It necessarily implies the maintenance of an international police force to compel states to observe the rules of international law. As such it involves serious difficulties, for obviously the force required to coerce effectively any one of the great powers of Europe with their huge powerful military establishments would necessarily have to be larger than anything we are accustomed to think of under the term "police." It is well known, for example, that France, single handed, held out for more than 20 years against a coalition of all the great powers of Europe and although finally overcome, emerged from the contest with her national boundaries little diminished.

A form of sanction recently proposed by a group of French jurists contemplates the application of the criminal law to individual violators of the rules of international law. Thus if a military or naval commander is charged with allowing those under his command to commit pillage, maltreat prisoners, kill non-combatants, sink a merchant vessel without warning or with violating other well-established rules of war law, he shall be traduced before the criminal courts and tried according to the procedure of the criminal law, or in case he does not fall into the hands of the authorities he will be tried *in absentia* and in case he is subsequently captured the punishment prescribed by the criminal law will be imposed. Like the other proposals suggested, this one would prove of doubtful efficacy in practice,

and grave practical difficulties would be encountered in the effort to apply it.

One truth has been clearly established by the results of the European War, namely, that a different attitude should be adopted by the nations toward violations of the rules of international law by a particular state. This attitude should be that which the community adopts when its own law has been transgressed by an individual. In that case the injured victim is not left to redress his own injury, but the community which has itself been injured by the violation of the law intervenes and punishes the act. Heretofore nations, however, have acted on the theory that when a rule of international law has been violated it is of no concern to any state except the particular one immediately wronged, and therefore they are strangers to the controversy. As ex-Senator Root has well said: "If the law of nations is to be binding, if the decisions of tribunals charged with the application of that law to international controversies are to be respected, there must be a change in theory, and violations of the law of such a character as to threaten the peace and order of the community of nations must be deemed to be a violation of the right of every civilized nation to have the law maintained and a legal injury to every nation. When a controversy arises between two nations other nations are indeed strangers to the dispute as to what the law requires in that controversy, but they cannot really be strangers to a dispute as to whether the law which is applicable to the circumstances shall be observed or violated. . . . International laws violated with impunity must soon cease to exist and every state has a direct interest in preventing those violations which if permitted to continue would destroy the law. Wherever in the world the laws which should protect the independence of nations, the inviolability of territory, the lives and property of their citizens, are violated, all other nations have a right to protest against the breaking down of the law. Such a protest would not be an interference in the quarrels of others. It would be an assertion of the protesting nation's own right against the injury done to it by the destruction of the law upon which it relies for its peace and prosperity."

Until this change of attitude has been adopted by the world, nations will be free to observe or disregard at will the prescriptions of international law without fear of punishment except such as the particular aggrieved state may be able itself to impose. Under modern conditions the existing theory is wrong in principle, for the subversion of the law by one state necessarily destroys the protection which the law intended to provide for all states.

While the idea advanced by some persons of high repute that the whole body of international law has been discredited if it has not actually collapsed under the strain of the Great War cannot be admitted, it is nevertheless true that the war has conclusively demonstrated that certain of its rules will need to be altered while others will have to be abandoned because they have become obsolete. The introduction of the submarine, the mine, the torpedo, aerial craft and wireless telegraphy as instruments of warfare, to say nothing of other changes in the methods and conditions of conducting war, will necessitate a revision of the war code along various lines. Thus the employment of the submarine and mine in naval warfare has demonstrated the impracticability of the old form of close blockade with its cordon of ships in the immediate offing of the blockaded port. The American Secretary of State in a note of 5 March 1915, to the United States Ambassadors at London and Paris, stated that the government of the United States was prepared to admit that modern methods of naval warfare, and particularly the use of the submarine for defensive purposes, might make the institution of a blockade according to the old rules a physical impossibility. In other words, the "long range" blockade in which blockading craft is permitted to remain out so as to be beyond the range of torpedo boats or mines will have to be recognized as legal. Moreover, it is not altogether improbable that if the right of belligerent blockade is to be retained, a belligerent whose adversary is so circumstanced that he may easily draw oversea supplies through the ports of an adjacent neutral country, must be allowed a limited power of blockade in respect to such neutral ports, otherwise with present railway facilities the right of blockade if restricted to enemy ports will in many cases be useless. Thus the World War has shown that if the British right of blockade had been confined strictly to the ports of the enemy it would have been of little value to Great Britain because Germany could import unlimited supplies from America through the neutral ports of Holland, Denmark and Sweden.

Likewise, the old rules relating to contraband will need alteration. The results of the World War have largely demonstrated the unsoundness if not the ineffectiveness of the existing rules in respect to the carriage of contraband, and particularly those governing the destination of conditional as opposed to absolute contraband. Most of the rules formulated in the Declaration of London in regard to hostile destination are vague and some of them are illogical and rest upon no sound principle of reason or expediency. So the old rules governing the right of search have broken down in practice. According to the contention of the American government in the controversy with Great Britain in regard to British restraints on American commerce, the right of search can be exercised only on the high seas at the time and place of capture, and ships cannot be taken into port for further examination on suspicion not amounting to conclusive evidence. But the recent war has shown that with the increased size of ships and the magnitude of their cargoes, effective searches in many cases cannot be made on the high seas, and the vessels must therefore be carried into port where their cargoes can be unloaded and each parcel carefully examined. A new practice which may be confidently expected will be the furnishing of neutral vessels with certificates by representatives of the government under whose supervision the loading is done, declaring that the cargo is innocent. This done, the necessity for harassing searches, deviations to distant ports and ruinous delays to shippers will disappear.

The employment for the first time on a large scale of submarine vessels, submarine mines, asphyxiating gas and aerial craft has raised new and difficult problems, for the regulation of which there are either no existing rules or rules which are inadequate. One of the tasks which the war will bequeath to the international jurists of the future, therefore, will be the formulation of new rules or the modification of such rules as exist, in respect to the employment of these agencies.

The failure of the powers to ratify the Declaration of London leaves the law in respect to the transfer of flags, domicile, nationality and other matters largely in a chaotic state and further international legislation dealing with these matters will be necessary. The unprecedented encroachment upon the rights of neutral states which has marked the conduct of the World War should and doubtless will lead to the adoption of new and more effective rules for safeguarding neutral rights. The American Institute of International Law at its first meeting held in Washington in 1916 adopted a series of declarations defining the attitude of the American countries in respect to the rights of neutral states.

The wholesale internment in concentration camps by the belligerent states of the alien enemy population found within their territories at the outbreak of the war — a measure without precedent in the wars of the past — has given rise to the question of the treatment which a belligerent may legitimately mete out to such persons. This matter is unregulated by convention and should receive attention when the time arrives for revising and amplifying the existing rules of international law.

It is impossible within the brief compass of this article to discuss all the possible changes in the law of nations which will be made necessary or desirable in consequence of the new conditions of warfare and the employment of new methods and agencies of combat. That they are numerous and important must be evident to every student of the history of the war on its international law side. There is one contention, however, that must be emphatically rejected. It is the claim put forward in Germany in connection with their methods of submarine warfare, namely, that the resort to a forbidden practice is lawful provided the instrument used is of such a character that it cannot be used in conformity with the rules of law; in short, that a military or naval commander who owing to the peculiar construction of the agency which he employs cannot conform to the established law and practice is relieved from all obligation to observe the rule.

The invention of new instruments and methods of war will undoubtedly necessitate certain modifications in the existing body of war law, but it must be confidently assumed that the world is not prepared to admit that the long established rules of law devised in the interest of the sacred principles of humanity must be sacrificed in order to enable belligerents to employ agencies of destruction which cannot be employed without violating those rules. Whatever changes are made in other respects, the laws of humanity and justice which have received the common assent of mankind must remain unaltered and the employment of new inventions must conform to those laws or they must be discarded. Conditions are always changing and new and more powerful agencies of destruction are constantly being invented. If the rules of international law founded on considerations of humanity cease to be binding whenever conditions change or whenever new agencies of warfare are invented, it would be a play upon words to describe such a body of rules as a system of law. The same opinion must be held in regard to the contention put forward in Germany that military necessity knows no law, that whenever a belligerent interest conflicts with an established rule of law the rule may be disregarded. This doctrine of *Kriegsraison* as it is known in Germany is based on the view that a belligerent is bound by the laws of war only so long as they interpose no obstacle to the accomplishment of the objects of the war. If this theory should be admitted and sanctioned by international agreement by the powers it would be a surrender of much which civilization has gained during the past two centuries. There is no likelihood that it will be done. Consult Phillipson, C., 'International Law and the Great War' (New York 1916).

INTERNATIONAL PEACE CONFERENCE. See Hague Court, The.

INTERNATIONAL PEACE MOVEMENT, The. A world-wide movement aiming at the abolition of war, more especially international war. While fighting has always been one of the chief occupations of mankind; while ideas of national greatness are largely associated with battles, campaigns and sieges; and while the heroes of poetry, history and monumental art are mostly famous soldiers; in modern times, nevertheless, the opinion has rapidly gained ground all over the world that war is a terrible evil which ought to be prevented as far as possible, and sooner or later to be done away with altogether. Some writers, notably in Germany, defend it as a biologic necessity, contending that it is a phase of the universal struggle for existence and hence a part of nature's plan for securing race hardihood and keeping the growth of population within bounds. (See Malthusianism). Others, again mainly Germans (particularly Prussians), even glorify it as the noblest of human activities, a divinely ordered means of preventing the inhabitants of the world from becoming effeminate, pleasure-loving and morally flaccid. To this argument, however, the opponents of war reply that co-operation is just as much a part of nature's law as fighting, and that intertribal slaughter is a human specialty virtually unknown to the lower animals, among whom individuals attack and kill one another only for food. As for the moral benefits of war, moreover, it is urged that these come also from fire, flood, famine, earthquake and pestilence, which nobody thinks of listing among the good things of life; to a certain extent, also, good by-products come from dueling and private brawling, which almost everybody admits it is well to have got rid of.

Aside from the few extremists who extol war as a good thing, and those at the other pole who denounce it as the sum of all villianies and something to be avoided at any cost, the great mass of thoughtful men regard it as indeed an evil, but as sometimes a necessary

and praiseworthy alternative to still greater evils. They hold that slaughter and destruction on a large scale, with all of the attendant suffering and misery, constitute ethically the most inhuman, rationally the most absurd, and economically the most expensive mode of settling international conflicts of opinion and interest. Accordingly, they are working to bring about a form of world-organization in which the nations shall co-operate to abolish this ancient scourge and at the same time find a moral equivalent for its valuable by-products. In the year 1910 the well-known philanthropist, Mr. Andrew Carnegie, whose generosity rendered possible the creation of the great institution known as the Carnegie Endowment for International Peace, summed up the present-day attitude toward war by calling it «the foulest blot upon our civilization»—a characterization amply warranted by the colossal struggle of the World War, unless that struggle shall eventually prove to have been indeed a war against war.

This new attitude of aversion toward war is a part of the great humanitarian movement which set in shortly before the French Revolution. War violates the Rights of Man—the right to life, liberty and the pursuit of happiness. Its immediate effect is the destruction on a large scale of life itself, which has come to seem more precious than it used to seem, and also of many of the values, both material and spiritual, which ennoble life and make it worth living. It replaces the orderly constructive processes of society with an orgy of destruction, treating the common man as mere cannon-fodder, while its immediate benefits fall to only a few leaders who get their reward in «glory» or increased wealth and power, that is, in the gratification of their vanity.

In spite of all that, however, it is generally recognized that a brief frenzy of successful war *may* avert from a whole nation a long era of dependence, oppression, humiliation and economic misery. Hence war, particularly defensive war, sometimes justifies itself to the humane and philosophic mind as a preparation for a better time to come—it is a paroxysm in which the men and women of a particular nation and epoch sacrifice themselves for the sake of their descendants. Consequently sensible and conscientious peace-workers have no sympathy with the doctrine of «peace at any price,» but look upon peace rather as a by-product of freedom and justice, a state of affairs rendered desirable not merely by the absence of war, but by the presence of conditions that make for human welfare and happiness—conditions oftentimes not to be established by any other means than war itself. In his book entitled 'A World in Ferment' Dr. Nicholas Murray Butler expresses himself regarding peace as follows: "Peace is not an ideal at all; it is a state attendant upon the achievement of an ideal. The ideal itself is human liberty, justice, and the honorable conduct of an orderly and humane society. Given this, a durable peace follows naturally as a matter of course; without this, there is no peace, but only a rule of force until liberty and justice revolt against it in search of peace." It is necessary to distinguish, therefore, between the practically minded workers for international peace, who seek definite remedies for definite dangers and evils, and the radical pacifists, who condemn and denounce all war under all circumstances. In 1918 the sentiment of the influential and far-sighted peace-workers of the nations allied against Germany was almost unanimous in favor of a vigorous prosecution of the war to a victorious conclusion, that being considered the shortest and surest road to an enduring peace.

In view of the fact that war is only a means of overcoming a difficulty that exists between two more or less powerful groups, its abolition of course presupposes the substitution of some other means to that end. For we have no reason to expect that controversies between nations will ever entirely cease to arise, any more than we have reason to suppose that quarrels between individuals will ever come absolutely to an end. The fact of the matter is, indeed, that man is naturally a fighting animal; his instinct impels him to attack any fellow-being who provokes him or stands in the way of the realization of his desires or the obtainment of what he considers his rights. History and experience prove, moreover, that destructive wars, no less than private quarrels, sometimes originate in trivial causes which might have been removed.

Thus the International Peace Movement takes it for granted that controversies between nations are inevitable, and concerns itself with creating a state of affairs wherein nations will not hastily resort to war for the purpose of settling their disputes or achieving their ends. Its aim, in other words, is to gain time for discussion and the cooling of passion, and then to provide peaceful, legal and therefore honorable ways of adjusting differences. This is frequently done by diplomacy, many imminent wars having been happily averted by peaceful negotiations conducted by duly authorized representatives of the opposing groups. But diplomacy usually involves compromise, which, in turn, implies a willingness on the part of the disputants to make reciprocal concessions in the interest of peace. When a compromise cannot be effected and diplomacy is unable to bring about a settlement, the opposing groups have but three alternatives to choose from: (1) they can leave the question(s) at issue unsettled; (2) they can go to war; (3) they can submit the question(s) to an impartial court of arbitration for a decision in accordance with the principles of justice and reason. The first is always unsatisfactory, sometimes dangerous and not infrequently impossible; the second is coming to be considered more and more a hideous anachronism; and the third is the primary object of the movement under consideration.

The sentiment of the world at large against war is by no means of recent origin, although it has been greatly quickened during the past generation by reason of the fact that armed conflicts between nations involve no longer relatively small numbers of fighting men, but whole vast populations, combatants and non-combatants alike, with the result that they are more destructive and calamitous than ever before. It is true, however, that there have always been individual writers, Utopian dreamers, who were opposed to the settlement of controversies by force, not only because they were shocked by the suffering thus caused, but also because they saw that war outraged justice and substituted might for right. But while denunciations of war on these and other grounds have come down to us from the earliest days of recorded history, and are of comparatively frequent occurrence in ancient, mediæval and early modern literature, suggestions as to efficacious means of avoiding it, that is, as to acceptable substitutes for it, are relatively few and far between. The idea of resorting to arbitration has been envisaged by many high-minded and public-spirited men, but only here and there do we find feasible schemes for putting that idea into practice. Moreover, even if a few projects not altogether hopeless were proposed, they could not be put into effect until a large public sentiment was created in their favor. For as long as the popular masses remained ignorant of or indifferent to the evils of war, regarding it as glorious or as concerning a comparatively small number of leaders and fighting men, it was impossible that sporadic proposals looking toward the peaceful settlement of controversies and emanating from a few enlightened leaders of thought should lead to any practical results.

It is not strange that mankind has been very slow to realize that any controversy or difficulty which can be settled at all can be settled by law as well as by force. It has taken countless ages to do away with private brawling, and the world is by no means entirely rid of it yet. The truth is that war, in a certain sense, is a «time-honored institution,» that is, nations have always been in the habit of attacking one another whenever they have considered such action either necessary or desirable, whenever the war-passion has been aroused. Ancient action-patterns have developed in the nerve-substance of the human animal, so that when a stimulus is offered in the form of a real or imagined danger, or an insult, or a provocation of any kind whatsoever, we clench our fists or seize our weapons and get ready to fight, just as another sort of stimulus will move us to eat, or to tremble with fear of ghosts, or to seek the gratification of our sexual instinct. It has been shown that most wars, historically, result from land-crowding, need of expansion-room, but according to modern conceptions of right and wrong a nation which seeks to acquire territory belonging to another nation by force commits a crime analogous to that of the individual who steals his neighbor's corn and justifies the theft on the ground that he was hungry. However that may be, it is not to be denied that fighting is an ingrown habit and not a rational activity, and that the impulse to fight can be counteracted only by a long and slow process of education; at the same time, however, that education must provide a moral equivalent for war, lest enduring peace shall result in converting men from lions into sheep.

However we explain the phenomenon or account for its development, the fact remains that the sentiment against war has of late become more general and more insistent, with the result that at the present time the advocates of peaceful settlement are found in all classes of society and are becoming numerous enough to exert an important influence upon national and international affairs. Not only are enlightened peace-workers of many kinds (statesmen, philosophers, juris-consults, economists, journalists, historians, poets, scholars) constantly giving oral and written expressions to their views all over the world, but whole parties and sects have adopted the abolition of war (universal disarmament) as one of the main planks in their platforms. Moreover, constructive minds are everywhere engaged in advocating measures and developing plans for bringing about the substitution of a peaceful and legal procedure for war as a means of settling differences that threaten to involve nations; and the increasing number of international congresses and conferences held for the purpose of effecting a general agreement concerning all sorts of economic, commercial, political and social questions bears witness to the success of the efforts that are being put forth to the end of removing the causes known to be responsible for disastrous conflicts resulting in the wholesale destruction of life and property.

Since the beginning of the 19th century numberless peace societies of one kind and another have been created in different parts of the world, most of them without sufficient resources at their disposal for carrying on very extensive propaganda, but some of them large and wealthy enough to make their influence felt in the counsels of world politics. These peace societies, the first of which was founded in New York in 1815, and the second in London in 1816, may be called the mainspring of the International Peace Movement, since their membership includes the most prominent workers in all countries, and since they are constituted for the express and exclusive purpose of dealing with questions of war and peace. To a considerable extent they co-operate with one another, and while their policies and methods differ more or less, their objects, generally speaking, are identical and may be summarized as follows: (1) to educate public opinion regarding the evils of war and the advantages of peaceful settlement; (2) to advocate friendly agreement and co-operation in the regulation of matters affecting the family of nations; (3) to promulgate and popularize plans for the abolition of war and the perpetuation of peace; (4) to create in favor of such plans a public sentiment such as will incline responsible statesmen to apply them, with the necessary modifications, to the existing political conditions; (5) to bring about, ultimately, the establishment of an International Council or a Permanent Court of Arbitration to which all questions arising between nations shall be submitted by compulsion for adjudication on the basis of a universally accepted International Law.

It would be extremely difficult, if not impossible, to make out a complete list of the peace societies that have sprung into existence all over the world in the course of the last few decades, and especially since the beginning of the great World War in 1914. The fact of the matter is, indeed, that almost every little town, especially in the United States, has its peace society, so that there are literally hundreds of them. 'The International Peace Year-book' (1915), published by the National Peace Council (established in England in 1905

by the Second National Peace Congress of Great Britain and Ireland «to effect a closer union of the [British] societies, and to assist them in a sincere and earnest promotion of the world's peace») contains a list of peace societies covering some 40 pages; most of these mentioned do not claim an international character, however, while many of those which claim it scarcely possess it. Suffice it to say, accordingly, that there are at least 10 or 12 larger organizations, of which the Carnegie Endowment for International Peace may be called one of the most important, whose membership comprises the leaders of the peace movement in all countries of the civilized world, and whose activity is therefore truly international.

The question as to whether the world will ever be entirely rid of war is one which nobody can answer. It is «a consummation devoutly to be wished,» but it is by no means a foregone conclusion. If perpetual peace ever reigns on earth, it will be, as stated above, the result of a long and slow process of education. This may take a great many years, and meanwhile the stormy passions that make for war demand immediate action. Certain it is, at all events, that acceptable substitutes for war cannot be created over-night and the habit of resorting to arbitration for the settlement of international differences cannot be generated on the spur of the moment. Every day, however, the International Peace Movement is gathering more and more adherents and acquiring more and more momentum, and it is more than possible that this will ultimately result in the creation of a world-wide public sentiment strong enough to bring about the definitive banishment of the scourge of war from among civilized peoples.

INTERNATIONAL UNION OF MINE, MILL AND SMELTER WORKERS. See WESTERN FEDERATION OF MINERS.

INTERNATIONAL UNIONS FOR THE PROTECTION OF PROPERTY. **(1) International Union for the Protection of Industrial Property,** an organization with headquarters at Berne, Switzerland, which dates from 1880, and its first conference that year held in Paris, followed by another in 1883; Rome, 1886; Madrid, 1890 and 1891, and Brussels, 1899–1910. The work of the Union was brought prominently before public notice in the United States when the delegates met at Washington, 15 May 1911, to consider amendments and revision to the Treaty of Paris of 1883. President Taft selected five men prominent in the world of patents to represent the United States: Hon. Ed. B. Morse, Commissioner of Patents; Mr. F. B. Fish, Mr. Charles Duell, Mr. Melville Church and Mr. Robert H. Parkinson. The deliberations of the conferences are secret, and final texts of treaties as amended are not given out until ratified by the various nations represented.

The convention signed at Washington 2 June 1911 was ratified by representatives of Austria-Hungary, Dominican Republic, Spain, United States, France, Great Britain, Italy, Japan, Mexico, Norway, Netherlands, Portugal, Switzerland and Tunis. Five governments adhering to prior conventions which did not ratify were Belgium, Brazil, Cuba, Denmark and Sweden. Twenty other nations had been invited to take part and become adherents to the Paris Treaty of 1883 and its subsequent amendments, but did not respond. There was, however, evidence of increasing interest in the Union on the part of non-adhering countries. The date of the next conference to be held at The Hague was postponed indefinitely on account of the great European War.

(2) International Society for the Protection of Private Property.—A society reported 17 July 1916 as formed with headquarters in Zürich, Switzerland, to look after the interests of persons who own property in enemy countries which is liable to confiscation or enforced administration by the governments of warring nations. The Society pledges itself to try and persuade the respective governments to release the requisitioned property of enemy subjects, and also to take care of the interests of their colleagues, whenever possible. The members of the Society include a great many rich persons threatened with impoverishment in both of the warring groups, and several leading jurists in neutral countries interested in the problem that has arisen of private property having to protect itself against the state, which, according to current belief, should be the first protection of private property. The Society does not limit its activities to mere protests, but uses the most radical measures in case of necessity.

INTERNATIONAL WATERWAYS COMMISSION. See LAKE-TO-SEA COMMISSION.

INTERNATIONAL WORKINGMEN'S ASSOCIATION, an organization of the workingmen of all countries for the advancement of the interests of labor and the emancipation of the working classes. It grew out of a visit of French workingmen to the World's Exposition at London in 1862. In 1864 an organization was formed in London, and an 'Address and Provisional Rules' published; the rules provided for a general congress to be held annually and a central council appointed by that congress to sit in London; workingmen's societies were to join the International in their corporate capacity. The principles and policy were not then definitely announced; the first congress held at Geneva in 1866 passed resolutions favoring the limitation of the working day and the abolishing of child labor; at the next congress at Lausanne (1867) socialistic principles were first definitely announced; from this time the influence of Marx and his followers grew in the organization. In 1868 at the Brussels congress the International announced its opposition to war, and favored the general strike; at the Basel congress in 1869 Bakunin and the anarchists were admitted; but they were expelled from the association in 1872 at the congress at The Hague; this same congress transfered the seat of the General Council to New York. The anarchists held a separate congress at Geneva in 1873. In 1867 the International rendered substantial aid to the strike of the bronze workers in Paris, and the next year to the strike of the Geneva builders; it assisted the English workmen by preventing the importation of underpaid laborers from the Continent in time of strikes. The International was accused of complicity in the Paris Commune, and while the two had no official connection many of the leaders of the Commune were Internationalists, and its principles and aims were defended by the International. In the United States the Social party, a socialist political organization, was affiliated with the International in 1868, and later some individual trades-unions were also affiliated; finally the North American Federation of the International was formed and held its first national congress in 1872; its organization was in local sections of at least 10 members, with a Federal Council of nine elected by the annual congress. Shortly after the transfer of the General Council to New York the Internationalists took a prominent part in the eight-hour day demonstration in New York. The formal organization of the International was dissolved in 1875; in Europe the Social Democratic parties of the different countries grew out of it, and in the United States the Socialists-Labor party. The anarchist faction in the United States split into two organizations, the International Workingmen's Association and the International Working People's Association. The International was important in the history of the labor movement as being the first expression of the recognition of the common interests of labor in all countries, and as being the means of spreading widely the knowledge of the principles of the Marxian socialism. Consult Brooks, J. G., 'The Social Unrest' (New York 1903), and 'American Syndicalism' (New York 1913); Ely, R T., 'French and German Socialism' (New York 1883), and 'The Labor Movement in America' (New York, new ed., 1905); Kelly, E., 'Twentieth Century Socialism' (New York 1910).

INTERNODE, in a plant, the portion of the stem between two nodes or leaf-buds; a portion of any elongated body between two nodes or thickenings. See STEM.

INTEROCEANIC SHIP CANAL. See NICARAGUA CANAL; PANAMA CANAL.

INTERPARLIAMENTARY UNION FOR INTERNATIONAL ARBITRATION, an association composed of members or ex-members of the legislatures of the world, formed to promote a peaceful settlement of international disagreements. It was organized at Paris in 1889, but the United States did not send representatives until 1897. In the early 90's its work was so earnest in the interest of international peace and arbitration that an international court was proposed, with jurisdiction in such matters. The Hague Tribunal was the outcome. The later activities of the association have been aimed to secure the adoption between nations of permanent treaties of arbitration. See ARBITRATION; INTERNATIONAL; HAGUE TRIBUNAL, THE.

INTERPELLATION, *in law,* the act of demanding an official explanation of a member of the government, as in France and some other European countries. It is used more frequently in Italy and France than elsewhere. After due notice, any member of the particular legislative body may interpellate the ministry, and this often results in a general debate. Frequently a ministry resigns as a result of an interpellation. The right of permitting or refusing an interpellation rests with the legislative body, not with the ministry. An interpellation is followed usually by a vote of confidence or of want of confidence in the government.

INTERPLEADER, *in law,* a procedure by which a person having goods, money or the like in his possession may have the ownership thereof judicially determined in case of dispute between two or more claimants. Usually such a suit is brought in equity. It is called «multiplepoinding» in Scots law. One seeking this remedy must show that two or more persons claim against him the same thing, obligation, etc.; that he is not in collusion with any of such parties; that he has no beneficial interest in the subject matter of the suit; that he cannot decide without danger of prejudice to his rights who is the rightful claimant, and must show that he is willing to meet his obligation to the lawful owner. Originally this action was restricted to a limited number of cases, but it has been extended so that to-day it may be brought in all claims in which the right or obligation is identical. It is of importance in modern practice, both in Great Britain and in the United States, in the relations involving bailor and bailee, landlord and tenant, common carrier and shipper, tax-collector and landowner, agent or consignee and principal or consignor, sheriff and party claiming goods levied upon, etc.

INTERPOLATION, a word, line, verse, sentence, part of a sentence or whole passage, inserted usually with a view to secure respect for some opinion by the apparent support of antiquity, or of those whose authority is greatest. Many instances of interpolation are well known, and others are with great probability suspected, in which the works of early Christian writers have been tampered with, to make them yield support to novel doctrines and practices. *In mathematics* the operation or method of finding, from a few given terms of a series, other intermediate terms. Interpolation is frequently resorted to in astronomical calculations. Consult Doolittle, C. L., 'Treatise on Political Astronomy as Applied to Geodesy and Navigation' (4th ed., New York 1903).

INTERPRETATION, *in law,* the art of determining the meaning of a speaker or a writer or of the parties to a written instrument, as a contract, deed or the like. Courts of equity, in their interpretation and construction of instruments, follow the same rules as courts of law. The terms interpretation and construction, while frequently used interchangeably by some writers, should be differentiated according to others. In interpretation, they contend, the court decides simply the meaning of words and sentences, whereas in construction the court decides what is their legal effect. Interpretation is merely logical reasoning, while construction is legal reasoning, these writers insist. The two terms, nevertheless, in practice at least, are generally used with identical meaning. The rules for interpretation vary to some extent with the particular class of instrument in dispute. For instance, wills are liberally construed, as the testator is not presumed to know the legal signification of all the terms he employs, but is held to use such in their popular meaning. On the other hand, a deed is generally construed strictly and against the maker when there is ambiguity. A contract must not be strictly nor liberally construed, but the intention must be drawn in the light of surrounding circumstances, as customs of the place or

time, social conditions, etc. Statutes abrogating the common law, as well as penal statutes, must be strictly construed. The same rule is applied to statutes affecting private rights. On the other hand, statutes designed to prevent fraud are liberally construed, and statutes must generally not be construed so as to operate retrospectively.

Some general rules of interpretation are as follows: (1) The meaning of a word, clause or other part of an instrument must be construed in the light of the whole instrument. Such disputed part may have its ordinary meaning entirely changed by this rule. (2) The meaning of the maker of an instrument is to be taken from what is therein contained and also from what may be fairly implied by custom or the like. (3) Due weight must be given to the construction placed upon the instrument by the parties themselves. (4) Words are to be taken in their ordinary meaning unless the writing or the attending circumstances indicate a contrary intention. (5) Where two interpretations are possible, that is to be preferred which is fair and reasonable. (6) Usually ambiguous language is to be construed against the maker of a private writing, as a contract or a deed. (7) When the language of an instrument is clear and unambiguous, interpretation is not needed. In other words, a court will not read into an instrument a meaning it does not express, even if the court does not believe the language expresses the meaning of the maker. (8) As between two interpretations, one of which follows the law and the other does not, the former is to be preferred. (9) A writer cannot be allowed to vary, contradict or add to an instrument by oral evidence to show his actual intention.

In addition to the foregoing list, which is not complete, a large number of special rules have been framed to fit particular cases.

Sometimes the interpretation of an instrument is left to a jury, but the usual rule is that the court decides. For instance, a jury may decide the signification of a written word which has a local or a trade meaning, and similarily a jury may decide the meaning of an oral contract or other oral declaration. In criminal libel cases in the United States, and in all cases of libel and slander in England, the jury likewise decides the meaning of the language employed by the defendant. This forms an important exception to the rule above enumerated.

Interpretation is particularly important in four classes of instruments: deeds, wills, contracts and statutes.

A highly technical classification of different methods of interpretation has been recognized by some authorities, such as liberal, close, restrictive, extravagant, strict, etc., but the first and last are the ones generally used.

An important doctrine, known as that of *cy près*, has been developed in the interpretation or construction of wills and statutes. Under this doctrine so much of the writing will be given effect as is possible. For instance, if an illegal direction is given in a will, so much of the will must be given effect as is legal, if this part is separable, and the remainder ignored. This doctrine is in effect both in Great Britain and in most of the States in this country.

In the interpretation of constitutions, the courts endeavor to harmonize different parts that seem to conflict, and should lean in favor of a construction which will render every word operative, rather than one which may make some idle and nugatory. (8 W. Va. 320). The rule for the construction of Federal and State constitutions is radically different. Consult 102 Tex. 11; 9 Wheat. (U. S.) 1.

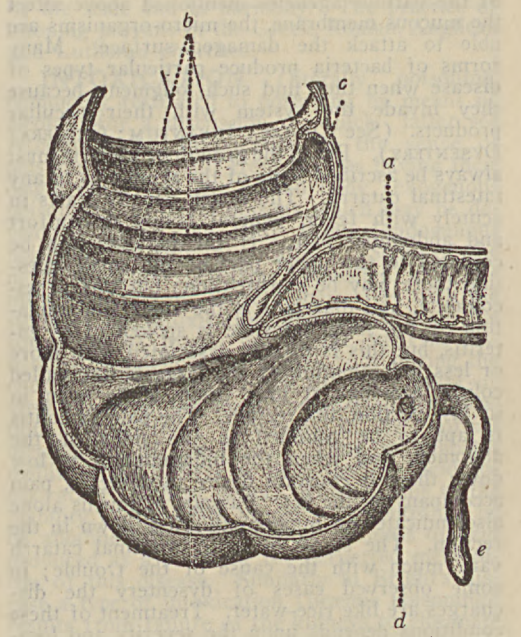
INTERVAL, in music, is the distance or difference of pitch, arithmetically expressed, between any two tones of a given scale. Occidental nations, including America, employ the diatonic scale (see SCALE), an octave comprising five tones and seven semitones, named after the first seven letters of the alphabet. The affix of a flat or sharp before a note denotes its quality but does not affect its name, and the eighth note being in unison commences a new octave. Taking the scale in the key of C major, the various intervals are: minor second = E–F or B–C; grave major second = C–D, F–G, A–B; grave minor third = D–F; minor third = E–G, A–C, B–D; major third = C–E, F–A or G–B; perfect fourth = C–F, D–G, E–A, G–C′, or B–E′; acute fourth = A–D′; acute augmented fourth = B–F; grave diminished fifth = B–F′; grave fifth = D–A; perfect fifth = C–G, E–B, F–C′, G–D′, A–E; minor sixth = E–C′, A–F′, B–G′; major sixth = C–A, D–B, G–E′; acute major sixth = F–D′; grave minor seventh = D–C′, G–F′, B–A′; minor seventh = E–D′, A–G; seventh = C–B, F–C′; octave = C–C′, D–D′, etc. By taking various notes of the diatonic scale as starting points and measuring known intervals from these, we arrive at intermediate notes of the scale, of which the following are examples: C♯ minor third below E; D♯ minor second below E; E♭ minor third above C; A♭ minor sixth above C; B♭ minor seventh above C; B♯ 3 major third above C. The difference of pitch between C and C♯ or between D and D♯ is called a semitone, and an interval increased or diminished by a semitone is said to be augmented or diminished. This applies especially to the interval of a fourth or a fifth, which with the octave are said to be perfect, because any augmentation or diminution mars their consonance. The major sixth or third may, however, be diminished to a "minor" sixth or third without destroying the consonance; and the term "minor" is also applied to the diminished second or seventh. Intervals confined within the octave are simple, when they exceed it compound; the octave beginning a new series, the ninth is the octave of the second, and so forth.

INTERVENTION, in international law, the meddling of one state in the internal affairs of another either for the protection of its own rights or those of its citizens or for some purpose usually humanitarian. It may take place under the form of representations to the Ambassador of the country against which it is directed, or that of armed interference. Its essence is illegality and it is only justified by its success. Intervention has been frequently resorted to, especially in Europe during the 19th century, when it often became necessary to secure the balance of power. It is safe to say that armed intervention is not favored except in extreme cases, e.g., the expedition to China during the Boxer Rebellion of 1900. Intervention on humanitarian grounds has at times been resorted to to cover the real object. Interventions under treaty guarantees have not been uncommon. Recent instances of intervention are that of the United States in Cuba in 1898 and England in the Great War because as a signatory to the treaty guaranteeing the independence of Belgium, which was ruthlessly violated by Germany. Consult Moore, J. B., 'Digest of International Law' (1906).

INTESTACY, the legal state of a person dying without having disposed of his property by last will and testament. In Great Britain intestacy does not affect real estate, which is disposed of in accordance with the rule of descent. The effect of intestacy in Great Britain is merely that no directions have been left for the distribution of personal property. The effect of intestacy in the United States varies in accordance with the laws of inheritance fixed by each of them. Intestacy may be complete, as when a valid will is not left by the dead proprietor; or partial, when the extant will only provides for the distribution of part of the property. In these cases the property passes to the heirs or next of kin of the decedent in accordance with the laws of the place where the property is. See DESCENT; HEIR; INHERITANCE.

INTESTINE, BOWEL, or **GUT,** the alimentary tube, in the higher animals limited to that portion between the stomach and the outlet at the anus. The human intestine is divided into the small and large intestine, the two parts varying in structure, movement and function. The small intestine starts at the pylorus of the stomach, as the duodenum, and the first 8 or 10 inches are so distinguished. This portion is the widest and most deeply placed of the parts of the small intestine. About three or four inches below the pylorus the ducts of the gall-bladder and pancreas open conjointly into the bowel. The duodenum emerges from the cover of the peritoneum and becomes the jejunum. The remainder of the small intestine constitutes the jejunum (about two-fifths) and the ileum. Between these divisions there is little difference, except that the jejunum is more freely movable, occupies the upper left portion of the abdomen more than the lower and right, and has thicker walls. The lumen of the small intestine gradually grows less from the duodenum, where it is two inches and a half in diameter, to little more than an inch where the ileum empties into the large intestine. The ileum is inserted several inches above the actual beginning of the large intestine, so that a blind pouch is formed below the point of juncture; this pouch, called the cæcum, gives off the appendix vermiformis (see APPENDICITIS) from its lower and back part. From the cæcum the large bowel passes up to the under surface of the liver as the ascending colon (see COLON), thence across the abdomen below the lower border of the stomach as the transverse colon, turns down to the iliac fossa as the descending colon, forms a peculiar S-shaped curve, the sigmoid flexure, which passes over the brim of the pelvis, where it is called the rectum (q.v.). The large bowel is about six feet in length. Both bowels have four coats, the mucous coat, the submucous, the muscular, and over most of the bowel an investment of peritoneum forming the serous coat. In the small intestine the mucous membrane is thrown up into permanent folds, each extending over half-way around the inside of the bowel. In this way a large surface is exposed for the absorption of food. Furthermore, the inner surface is covered with finger-like projection called villi, each having a large absorbing vessel in its centre. At the bases of the villi are tubular (of Lieberkuhn) and branching glands (of Brunner) that dip down into the mucous



Section of the Ileum and Cæcum; *a*, ileum; *b*, cæcum; *c*, ileocæcal valve; *d*, opening of the appendix; *e*, appendix.

membrane. Scattered over the surface there are tiny collections of lymphoid tissue, called solitary follicles, and here and there collections of these follicles into groups one to three inches long, called Peyer's patches. It is these spots that are attacked and ulcerated in typhoid fever. The muscular coat consists in an inner layer running around the bowel and an outer longitudinal coat. The large bowel differs from the small in the absence of the folds and villi, and is but slightly movable within the abdomen, being bound down to the abdominal wall posteriorly by the peritoneum. See PHYSIOLOGY.

Diseases of the Intestine.— These may be disturbances of the function of the bowels without actual inflammation, or they may be inflammations in different parts and of different kinds; but with inflammations there is necessarily a disturbance of the various functions, and differentiation frequently becomes a matter of difficulty. Diarrhœa and constipation (qq.v.)

are symptoms of many different conditions, as are also deficiencies of secretion and absorption. The nervous mechanism of the bowels may be changed, giving rise to abnormal sensations and disturbances of all the functions. True inflammation of the intestines is the most common cause of abnormal action, and therefore is described in detail.

Acute Intestinal Catarrh is an inflammation of the mucous membrane that varies much in its symptomatology with the part of the bowel affected and the causative agent. Among the causes may be mentioned the eating of tainted fruits and other foods; the overeating of any food; overdrinking, particularly of very cold liquids; the injection of chemical or mechanical irritants; "catching cold"; and the poisons of the infectious diseases. The bowel is inhabited by numerous forms of micro-organisms, many of which are entirely harmless; but when any of the various agencies mentioned above affect the mucous membrane, the micro-organisms are able to attack the damaged surface. Many forms of bacteria produce particular types of disease when they find such lodgment, because they invade the system with their peculiar products. (See CHOLERA INFANTUM; CHOLERA; DYSENTERY). But to the growth of bacteria must always be ascribed some of the symptoms in any intestinal catarrh. The attack usually starts in acutely with fever, general bodily discomfort and abdominal pain. If the inflammation be confined to the upper part of the small intestine there may be constipation; but this is uncommon, and diarrhœa is the rule. Inflammation of the small intestine is spoken of as enteritis, but this is usually associated with more or less inflammation of the large bowel, called colitis, although it may occur alone even in its last portion, the rectum. The pain in colitis is apt to be confined to the sides of the abdomen, and when the inflammation is low down there is constant desire to defecate, pain accompanying the act. Passage of mucus alone also indicates an inflammation low down in the rectum. The stools in acute intestinal catarrh vary much with the cause of the trouble; in some observed cases of dysentery the discharges are like rice-water. Treatment of these conditions depends upon the severity and location of the inflammation. The mild cases, with ordinary loose movements, recover without medication with abstinence from food for 24 hours. Castor-oil or small doses of calomel will cleanse the intestine of irritating substances. The more severe cases are kept in bed and allowed small amounts of milk after the first day, and are given small doses of castor-oil or mixtures of bismuth, opium and other sedative drugs. If the large intestine is found to be involved, irrigation with common salt in water (teaspoonful to the quart) is valuable. Great care must be used in the selection of diet for some time.

Duodenitis occurs associated with acute gastritis (q.v.), and has the same symptoms, except for the presence of jaundice due to the closure of the bile-ducts. The disease runs its course ordinarily in a few weeks without any treatment except rest in bed for a few days, simple diet and mild cathartics to relieve the constipation.

Chronic Intestinal Catarrh results from a severe attack of acute inflammation in which the mucous membrane is left with permanent changes, or from repeated attacks of inflammation. Cases of chronic inflammation may occur without previous evidence of acute attacks. The symptoms vary much in kind and intensity, but pain, flatulence and disturbance of the bowels are usually complained of. There may be pronounced constipation, alternating constipation and diarrhœa, daily unformed movements not distinctly diarrhœal, or, what is most common, a constant diarrhœa. More or less admixture of mucus in the stools is usually observed. Sooner or later there is apt to be a loss of flesh and strength. When the large bowel is much involved in such a process there is usually a coating of the stools with mucus, or the passage of clear mucus.

In the treatment it is best to rely mainly on carefully regulated life — exercise, baths, fresh air, sufficient rest, avoidance of exposure and properly selected diet. In diet the objects sought are the regulation of the bowels and the avoidance of irritation. When there is diarrhœa it is wise to avoid fruits, salads, cabbage, coarse-fibred breads, sugars, honey, pastry, sour and sweet wines and carbonic beverages. In cases attended with constipation most of these may be allowed, but sausages, rich dressings, cucumbers, cabbage and very coarse-fibre breads should be forbidden. Mineral waters are frequently used with success, such springs as Carlsbad and Vichy for the diarrhœal cases, and such as Marienbad, Hathorn and Congress for those attended with constipation. Chronic catarrh of the large bowel is treated with small doses of castor-oil and irrigations of the bowel with water, to which may be added antiseptics or astringents.

Intestinal Hemorrhage, or blood passed from the bowel, may be due to piles, tumors, dysentery, colitis, typhoid fever, tuberculosis of the intestinal tract, ulcers of the duodenum, portal obstruction as in cirrhosis of the liver, hemophilia, purpura and the hemorrhagic forms of the infectious diseases. When blood coming from the stomach or high up in the small intestine is passed by rectum it is changed to a tarry appearance This is due to the action of the digestive juices and bacteria. The farther down the intestine the blood starts, the brighter red is it found when passed.

Intestinal Obstruction is a term that includes a great variety of conditions in the abdomen having the common feature of obstruction to the passage of the contents along the bowel; and in addition there is in the acute condition some injury to the bowel resulting in special symptoms. Two varieties are differentiated, the acute and the chronic. Acute intestinal obstructions are caused by foreign bodies, gall-stones and hardened or large collections of fæces in the canal; by contracting scars, or tumors of the wall, twists of the gut (volvulus), intussusceptions (invagination of a portion above into the part below); by adhesions of the peritoneum, causing constricting bands; and by strangulations of portions of the bowel contained in hernia. Besides these causes, from local or general peritonitis there is apt to be a condition of paralysis of a portion of the bowel, giving rise to the same state. The symptoms vary considerably with the cause of the obstruction and the part of the bowel affected, but in general the symptoms are pain — frequently of a colicky sort — constipation, inability to pass gas — with resulting tympanites — vomiting, first from the shock, and later from reversed peristalsis, until at length the vomitus is bilious and finally even fæcal. Because of these symptoms and the injury to the nerves of the intestine resulting in "shock," there is a gradually increasing prostration. Certain features indicating that the obstruction is in the small intestine are early vomiting, the passage of fæces from the lower bowel and the greater swelling of the centre of the abdomen. Absolute constipation from the first is apt to mean an obstruction low down in the large bowel. The cause of the obstruction may be indicated by the presence of a tumor, or by something in the previous history. Intussusception is the most common cause of the obstruction in children; a tumor may be felt on the outside, or the bowel may be felt in the rectum. Fæcal impaction is indicated by a long history of constipation, and rectal examination shows the hardened masses. If intestinal obstruction be not relieved, the patient may die of shock, with gradual exhaustion, from gangrene of the bowel — the blood-supply being usually shut off — and sometimes from peritonitis.

Medical measures for the relief of most forms of the malady are not successful, and temporizing is attended with danger; but rest of the body as a whole and especially of the intestinal tract must be absolute. Some authorities advise the use of opium for further quieting the intestine when the diagnosis is certain. Lavage of the stomach is of great value, and large enemata may be curative when the cause of the trouble is intussusception, foreign body or hardened fæces. Most forms of obstruction require the opening of the abdomen, search for the cause of the obstruction, and attempts at removal. Results depend on the quickness with which operation is undertaken; death may ensue, in spite of the removal of the obstruction, if interference be too long postponed. Chronic intestinal obstruction is caused by about the same conditions as the acute variety The symptoms include various digestive disturbances, flatulency, constipation, and, when due to malignant growths, the general loss of flesh and strength

Intestinal Parasites.— Three principal forms of these affect man — tapeworms, roundworms and pinworms (qq.v.). The list of symptoms attributed to the presence of tapeworms in the human intestine is long and varied, but even loss of nutrition from such a parasite's presence is usually slight. Finding the worms or their eggs in the stools is the only convincing symptom. Treatment of this condition consists first in the preparation of the intestine by light diet for 24 hours before the tænifuge is given and six or eight hours before, allowing a liberal diet of onions, salty herring and garlic; this rather loosens the worm's hold. Mild purgatives may also be given at this time. Early on the following morning the selected drug is taken, and this may be either male-fern, pomegranate, pumpkin-seed, kousso or kamala. After about 12 hours a brisk cathartic is taken and the worm is passed. Careful search must be made for the head, for unless it is passed treatment must be started again while the worm is yet weak. Santonin and purgatives effect expulsion of roundworms. In the treatment of pinworms it is customary to take advantage of the fact that the females deposit their eggs in the large intestine and rectum. Santonin and cathartics aid in gathering the worms where they may be killed by injections of benzine (20 drops to the pint of water), or by solutions of quinine, though further catharsis may be necessary.

INTIMIDATION. See CORRUPT PRACTICES ACTS.

INTONING, the practice of delivering prayers in the recitative form. Intoning differs little from chanting: in the latter case the cadence is more developed, the divisions more rhythmical and the music in continuous harmony. In intoning the greater part of the prayer is recited on one note and then sung by several voices in unison, the closing words of the sentence being sung to the proximate notes of the scale and in harmony. The practice of intoning prevails in the Greek, Roman, Anglican and Lutheran churches.

INTOXICATION (literally poisoning, commonly restricted to poisoning by means of alcohol, for a discussion of which latter see ALCOHOLISM). Intoxication in the sense of poisoning may result from poisons having their origin outside of the human body (exogenous poisoning), or from poisons which may be developed within the body itself (endogenous poisoning, or auto-intoxication). Some of the most important problems connected with the infectious diseases concern themselves with the study of the intoxications that result from the formation of toxins by specific bacteria distributed throughout the human body during the course of a disease. From the same point of view many of the most complicated intoxications result from variations in the normal metabolism of the body. Thus in diabetes mellitus (q.v.) there is developed an acid intoxication (diabetic coma), which is due to the inability of the body properly to neutralize by its alkaline salts the excessive amounts of acid produced as a result of the perverted metabolism of this disease. Similarly in Bright's disease a type of intoxication (uræmic poisoning) results from failure of the kidneys to eliminate poisonous products from the human body. It seems not unlikely that a number of diseases such as migraine (sick headache), some forms of epileptic convulsions, different types of skin-eruptions and some of the mild insanities result from auto-intoxication (q.v.). See TOXICOLOGY.

INTRA, Italy, town of Piedmont, province of Novara, on the western shore of Lake Maggiore, 12 miles north of Arona. It has good water-power facilities which are utilized by its cotton and silk mills, foundries, hat factories, leather works, etc. Its industries are largely the property of the Swiss who inhabit splendid villas along the lake front. Pop. 8,000.

INTRANSIGENTES, or INTRANSIGEANTS, in France, Spain and Italy, extreme radical republicans; the party of irreconcilables. In Spain the Intransigentes combined with the Internationals in an extreme communistic movement of insurrection in 1873 against the federal republic.

INTRENCHMENT, in fortification, any work, consisting of not less than a parapet

and a ditch, which fortifies a post against the attack of an enemy. As a means of prolonging the defense in a regular work of permanent fortification, intrenchments are made in various parts, to which the defenders successively retire when driven in from forward works. Bastions are ordinarily intrenched at the gorge by a breastwork and ditch, forming either a re-entering angle or a small front of fortification. An army in the field often strengthens its position by intrenchments, as by a continual line of parapet and ditch, or by a line with intervals, consisting of detached works of more or less pretension flanking each other. The war in Europe, which began in 1914, was marked by an unprecedented system of intrenchment, with shelters, dug-outs, barbed wire obstacles, etc. See FORTIFICATION; WAR, EUROPEAN.

INTRODUCED SPECIES. A long catalogue might be made of species of animals and plants which have been transferred by accident or design from their native country or locality to other regions. Sometimes, as in the case of salmon in New Zealand, rabbits in Australia, the European house-sparrow in America and elsewhere, or Western fishes in Eastern waters, this is done by design; but in the great majority of cases the introduction is accidental and unwelcome, as in the case of the hundred and more species of injurious insects brought into the United States from foreign lands (or the fewer sent abroad from here), and the very many species of "weeds" naturalized on our and other shores. Such introductions are in the main accidental, the eggs or seeds or grown individuals passing from one region to another in ships or railway trains, or cargoes or discharged ballast; so many plants have been introduced by the latter means that botanists class the group of alien weeds as "ballast plants." See ACCLIMATIZATION; IMMIGRATION, ANIMAL AND VEGETAL.

INTROSPECTION, observation as applied to the phenomena of mind. While in essentials it is like all other observation, it is especially interesting because of certain difficulties which it encounters. Though these have been minimized by the experimental psychologist, they certainly burden psychological research with a very considerably greater degree of fallibility than that found within the natural sciences. As was pointed out by Kant, the chief obstacle to introspection is the fact that the phenomena forming the object of introspection are liable to profound modification by the act of introspection itself. It is indeed by no means inconceivable that objects within the mind may be as unmodified by the observation of an independent part of consciousness as non-mental objects. The difference between observation and introspection is thus in a sense merely one of degree; none the less it is not negligible. The crude introspection of common sense — which furnishes the only possible starting point for the refined introspection of experimental psychology — indicates to us that experiences are actually changed by a change in the direction of our attention. If one thinks intensely of the tip of his forefinger he will experience pressure sensations, temperature sensations, etc., which seem different from the casually remembered sensations experienced with a different direction of attention. If he listens to a particular instrument in an orchestra he will hear it as distinctly louder than if he listens to the orchestra as a whole. Now while the experiences which form the basis of our observation of nature are subect to change by our change of attention, in a manner not unlike our introspection, there is a fundamental distinction between the two cases. This distinction resides in the fact that whereas the apparatus of physical research reduces the experiences and phrases of experience involved to those which by their simplicity are not subject to much alteration by a change in the attention, all the instruments of the psychological laboratory cannot reduce by one iota the complexity and multability of the objects of introspection, for these constitute the entire content of the mind. Before this content can be studied by fragments with the aid of the apparatus of the psychological laboratory, it must be demonstrated by introspection that these fragments are really fragments of the more complex experiences. Introspection, therefore, can never free itself from a subject matter that changes with the direction of the attention by a mere choice of its objects. Now, introspection is itself a change of attention from the natural object of the experience to the experience itself. By its very nature, then, it may be expected to induce profound modifications in its objects. In order to avoid this, the psychologist trains himself to make introspection a more or less automatic act, requiring a relatively slight diversion of attention. While this is unquestionably the only method to gather a large mass of introspective data with relatively slight modifications by the method by which they are recorded, it is subject to grave dangers of its own. A prolonged training in laboratory introspection is likely to give one a somewhat narrow repertory of introspective terms borrowed largely from the senses of vision and hearing, and possibly inadequate to the tasks of introspection which are likely to be undertaken. The schematization of the process of introspection may well be inseparable from a schematization of its dicta. That mental phenomenon known as suggestibility makes it scarcely a matter of doubt that in many cases the introspection of one trained in the methods and doctrines of some special psychological school will contain artifacts, not present in the actual mental occurrences.

Besides the difficulties dependent on the attention and on suggestion, another obstacle to introspection is the privacy and inaccessibility of every experience. While no single observation in physical research can be repeated as such, or shared by several observers, the observation of several experimenters with respect to a given occurrence possess a certain equal weight and direct comparability, while the history of physics shows that it is possible to repeat many an experiment in practically all its significant details. While psychological experiments can be repeated, and many times with valuable results, as soon as the more complex processes — and particularly those of affection — are involved, the variation in the mental content and background from time to time becomes an obstacle that can only partially be circumvented. Physical experiments in heat and electricity can only be repeated by virtue of the existence of thermal and electric insulators. Chemical experiments demand apparatus that is inert to the reagents. Now, there is no thoroughly satisfactory way of insulating an experience of any degree of complexity from its mental background, nor of enclosing it, as it were, in an inert container. Thus it is difficult to repeat an introspective situation in such a manner as to duplicate all the features which are important from a given standpoint. The impossibility of sharing an introspection needs no comment. It has been said that every introspection is retrospection. This is true in a sense, for manifestly no complete view can be taken of a time-consuming experience — and all experiences, as far as we know, consume time — until the beginning of it is in the past. However, the knowledge of an occurrence in the immediate past need not be a matter of memory, for it appears that the direct cognitive relation can bridge brief intervals of time. This direct nature of immediate retrospection permits the psychologist to make many valuable introspections on chance states, the excitation of which in the laboratory would be difficult or impossible. The result of the foregoing discussion, then, is: Introspection is the fundamental method of psychology and is a valid type of observation but is subject to certain grave and peculiar difficulties which are at any rate less apparent in other types of observation. These are in part alleviated, in part aggravated, by the methods and practices of the psychological laboratory. These methods and practices have at best a limited scope and cannot be said to have supplanted the older method of introspection upon the psychological phenomena of daily life. (See PSYCHOLOGY). Consult James, W., 'Principles of Psychology' (New York 1899); Klemm, O., 'History of Psychology' (ib. 1914); Kulpe, O., 'Outlines of Psychology' (tr., ib. 1901); Titchener, G. B., 'Text-Book of Psychology' (ib. 1910); Wundt, 'Essays' (Leipzig 1906).

INTRUSION. See VOLCANISM, and section on *Volcanism* in article on GEOLOGY.

INTUBATION, the introduction of a tube into an orifice or an organ, as the larynx, to keep it open. Specially designed tubes for such a purpose are sometimes used in cases of croup, diphtheritic obstruction, etc., as a substitute for tracheotomy.

INTUITION, *in philosophy,* immediate knowledge, attained without deliberation or reasoning, as opposed to empirical knowledge which is built up by experience. The term has wide use in connection with intuitional systems of ethics which set forth conscience as a function which gives direct recognition of right and wrong, either in a choice between two acts, or between two principles of action. In the theory of knowledge intuition is the immediate apprehension of truth, whether that be sensory truth or necessary forms of thought, or ultimate knowledge of the nature of God, etc.

INTUITIONISM, a term used to designate loosely a wide range of philosophic theories in metaphysics, ethics and æsthetics, among which the common feature is an insistence upon the existence of direct, immediate apprehension of truth, beauty or right, without any necessary dependence upon experience. In general such philosophic tendencies are set over against empirical theories. The latter have generally carried the day in modern philosophy; in so far at least as concerns the recognized necessity for the action of experience in order to give solid foundation for belief, opinion and theory of every kind. In modern literature the term has its most important bearing in ethical affairs. See EMPIRICISM; EPISTEMOLOGY.

INTUSSUSCEPTION, the reception of one part within another, as of a sword in a sheath; as applied to the bowels, it expresses the slipping of one portion of the intestines into and constriction of another. It is a rather common form of intestinal obstruction, especially in infants, among whom over 25 per cent of all cases occur. It is fatal unless removed by surgical operation. In plant physiology, the term signifies the growth of a cell-wall by taking up new matter throughout, instead of laying it on by opposition.

INULIN, a substance resembling starch, but intermediate in nature between that body and the gums. It occurs in the roots of elecampane, dandelion and certain other plants, and also in the Jerusalem artichoke and the common potato. When pure it is a tasteless white powder consisting of spherical particles. Its chemical formula is probably a multiple of $C_6H_{10}O_5$, though $C_{72}H_{124}O_{62}$ has been suggested. It is insoluble in alcohol and but slightly soluble in cold water, although it is very hygroscopic. It dissolves freely in hot water. It melts at 320° F., becoming thereby converted into a different substance known as "pyro-inulin." It is not fermentable and does not reduce Fehling's solution. Iodine renders it brown or yellow.

INUNDATIONS, floods caused usually by the overflow of a river or by the ocean, sometimes by the giving way of a dam or other barrier. Since the dawn of history no century and scarcely any large country have been free from floods. The region of the Nile in Egypt, and of the Hoang-Ho, or Yellow River, in China, have suffered most from this cause; and the Nile stands alone as at once a terribly destructive and a beneficial agent, for its overflows have not only irrigated the surrounding dry country, but greatly enriched it by spreading over it the fertilizing sediment collected and conveyed in the stream. In recent years sanitary science has greatly reduced the danger of pestilence that always follows a great flood, and that formerly was often as destructive of human life as the floods themselves.

The following are some of the most noted inundations of record: 245, the sea swept over Lincolnshire, England, and submerged thousands of acres; 353, a flood in Cheshire, England, destroyed 3,000 lives and a great number of cattle; 738, an overflow of the Clyde drowned 400 families in Glasgow; 1014, a number of seaport towns in England and the Netherlands were destroyed; 1100, the coast of Kent, England, was deluged and the Goodwin Sands bank formed by the sea; 1108, Flanders was submerged by the sea and the town and harbor of Ostend completely covered; 1134, a large part of Flanders was again submerged; 1164, a considerable part of the coast of Friesland was swallowed up; 1170, many miles of country in the northern part of Holland were engulfed with great loss of life; 1219, the break-

ing of the dykes along the Zuyder Zee caused great destruction of life and property; 1277, 44 villages in Holland were destroyed; 1282, 72 towns and villages in Holland were submerged and 100,000 persons drowned; 1287, another breaking of the dykes caused a loss of 80,000 lives; 1362, 30 villages on the coast of Nordstrand were destroyed; 1377, 50 miles of territory and 72 villages in Holland were swept away and the course of the Maas and Rhine rivers changed; 1421, by the breaking of the dyke at Dort 10,000 people in the town and 100,000 in the vicinity were drowned; 1530, a general failure of the dykes caused an overflow of the low lands and a loss of life estimated at 400,000, and of property in proportion; 1570, Antwerp, Bruges, Hamburg, Rotterdam and Amsterdam were submerged and 30,000 inhabitants drowned; 1617, 50,000 persons were drowned in a flood in Catalonia, Spain; 1634, a flood swept away several villages on the Nordland coast of Denmark, and drowned 11,000 people and 66,300 cattle and 10,800 people and 90,000 cattle were drowned at Hamburg, Bremen and Oldenburg; 1717, the «Christmas» flood along the entire north coast and in England totally destroyed 5,000 dwellings and 3,500 partially; 1787, mountain torrents drowned 2,000 persons in Navarre, France; 1811, 24 villages near Presburg and nearly all their inhabitants were swept away by an overflow of the Danube; 1813, large provinces of Austria and Poland were flooded and many lives lost (6,000 in Silesia, and 4,000 in Poland), and 2,000 Turkish soldiers on an island near Widdin were drowned by a sudden overflow of the Danube 1816, the overflow of the Vistula River laid 119 German villages under water, and caused great loss of life and property; 1829, the same river broke through the dyke at Dantzig, drowned a large number of people and destroyed 4,000 dwellings and 10,000 cattle; 1830, an overflow of the Danube at Vienna flooded the homes of 50,000 inhabitants; 1833, 10,000 horses were swept away, and 1,000 persons drowned in Canton alone during the great October flood; 1840, a rising of the Saone river, France, and the bursting of its banks, caused 60,000 acres to be submerged and many houses destroyed in Lyons, Avignon, La Guillotière, Voise, Marseilles and Nismes; 1846, by the Loire flooding the centre and southwest of France, $20,000,000 damage was sustained; 1849, 160 squares and 1,600 buildings were flooded in New Orleans; 1852, the Hoang-Ho, in China, burst its banks, cut a new bed into the Gulf of Pechili and wrought tremendous losses; 1855, Hamburg was half submerged and suffered enormous property damage; 1861, Bengal, India, suffered great loss of life and property by a deluge in its most fertile districts, and famine and pestilence followed; 1866, the north of England was visited extensively by floods; 1870, Rome, Italy, suffered great loss; 1874, the bursting of a badly constructed dam caused the destruction of several villages in the valley of Mill River, Mass., and loss of 144 lives; 1876, destructive flood occurred in France and Holland; 1882, many persons were drowned and much property destroyed by overflows in the Mississippi and Ohio valleys; 1887, the Hoang-Ho, China, broke its banks, deserted its natural bed, spread over a thickly populated plain, cut an entirely new road to the sea, washed away 300 villages, and submerged the lands around 300 more between Cheng-Chou and Chung-mon, submerged more than 1,500 villages south of Kaifeng, rendered 2,000,000 people homeless and caused a loss of life estimated from 1,500,000 to 7,000,000; 1889 (31 May), the giving way of the Stony Creek dam in the Conemaugh Valley, Pa., caused the total destruction of the city of Johnstown and several neighboring towns, and caused a loss of about 5,000 lives and more than $20,000,000 of property. The same year was marked by very disastrous floods in China and Japan. In 1890, the levees of the Mississippi gave way in many places, and the waters flooded large areas of land in Mississippi and Louisiana. The worst crevasse was caused by the giving way of the Morgansea, near Bayou Sara. In 1903 there was a great rising of the Kansas, Missouri, Mississippi and Des Moines rivers; several large cities, including Kansas City, Des Moines and Topeka, were inundated, the loss of life was over 300, and of property about $10,000,000. In the same year Paterson, N. J., and the entire Passaic Valley were flooded, about $3,000,000 damage being done in Paterson. In 1912 the Mississippi inundated 15,000 square miles with a damage to property estimated at $45,000,000. In March–April 1913 a most destructive flood occurred in the Ohio Valley, due to an excessive rainfall within a short period, 400 lives were lost and the damage to property reached $180,000,000. The city of Dayton was almost destroyed. Early in June 1921, a flood in Pueblo, Colo., cost 500 lives and $25,000,000. Consult Stoney, 'Extraordinary Floods in Southern India' (London 1898); Williams, 'Effects of Land Floods in a Tidal River' (London 1891); Mississippi River Commission 'Reports.'

INVALIDES, Hôtel des, an establishment in Paris where wounded veterans of France are cared for at the public cost. Its foundation dates from 1671, under Louis XIV; at first it was a place of retirement for the aged servants of court favorites as well as for invalided soldiers, but this abuse was ended by St. Germain in the reign of Louis XV. With its high gilded dome, under which are the tombs of Napoleon, Turenne, Vauban, Jerome and Joseph Bonaparte, and Marshal MacMahon, it is one of the most conspicuous monuments of Paris. The buildings, which cover about 30 acres, were begun in 1671 and completed in 1675. They furnish accommodation for 6,000 inmates. The façade of this last structure is 660 feet in length. It stands about 600 yards back from the Seine, facing the Esplanade des Invalides, a fine open place about 900 feet wide, containing several rows of trees and extending to the river opposite the Champs Elysées. In 1789 the private property of the institution was alienated and it has since been supported from the public revenue. The body of Napoleon rests in the crypt of the dome.

INVAR, an alloy of nickel and steel with exceedingly small coefficient of heat expansion, only one-twenty-fifth that of steel. It is used for measuring-rods in geodetic work, for pendulums and other purposes where liability to heat expansion vitiates accurate work. It contains 36 per cent of nickel. The name is a condensation of the word invariable. See CLOCK and GEODESY.

INVARIANTS AND COVARIANTS.

1. These terms were introduced and are still ordinarily employed, in connection with a special mathematical theory, namely, the theory of the linear transformation of algebraic forms developed by Cayley and Sylvester during the middle third of the 19th century. The central idea, however, is a very general one, which has been applied in recent years to almost all branches of mathematics. It deserves, in fact, to be ranked with such fundamental concepts as function and group. We therefore divide our sketch into three parts as follows: (1) The general concept of invariant; (2) the theory of algebraic forms, or invariants in the narrow sense; (3) other invariant theories.

The General Concept.

2. The suggestion for the formation of the concept comes from the familiar observation, at the bottom of all science and philosophy, that, while the world about us is in a continual state of change, there are yet certain aspects or properties which are unaltered. To find the permanent in the changing is the most general statement of the problem of invariants. Abstractly, the idea may be explained more definitely as follows: Consider a set of objects or elements O of any conceivable kind, finite or infinite in number; and a set of operations or transformations T, each of which interchanges the objects in a definite manner. Then a property of an object O is said to be *invariant*, provided it holds for all the objects obtained from the given O by the transformations T. Similarly, any relation between a number of O's which holds for the transformed O's is said to be an invariant relation, that is, an invariant relation of the given objects with respect to the given transformation.

The idea of *covariant* involves nothing essentially new. An object $\bar{O}$ is said to be a covariant of a given number of objects O_1, O_2, etc., provided $\bar{O}$ is invariantly related to O_1, O_2, ... In this case, if any one of the transformations T converts $\bar{O}$ into $\bar{O}'$, O_1 into O_1', O_2 into O_2', etc., then the relations connecting $\bar{O}'$ with O_1', O_2', etc., are the same as those connecting $\bar{O}$ with O_1, O_2, etc.

3. The idea is best illustrated by examples from geometry. Consider a number of points P_1, P_2, ..., connected with a solid body. When the body is displaced, its points take new positions, P_1', P_2', ... Many such positions are possible, since the displacement may be made in an endless number of ways. But in every case, of course, the distance between P_1' and P_2' is the same as that between P_1 and P_2. That is, distances between points are invariant with respect to rigid displacement.

Suppose next that the solid carrying the points is not only displaced but is magnified (or diminished) according to any scale. (We may, for example, picture such a change as produced by subjecting the homogeneous solid to a higher or lower temperature). The solid is then converted into one of different size but of the same shape, that is, a similar solid. Distances are changed in the same ratio. Hence $P_1'P_2'/P_2'P_3' = P_1P_2/P_2P_3$. That is, the ratio of any two distances is invariant with respect to similitude transformations.

4. In both examples, points on a straight line are converted into points on a straight line. Collinearity is then a relation which is invariant with respect to displacements and similitude transformations. A more general type of transformation for which this is true is the homographic or projective transformation. We consider, for simplicity, only the case of figures drawn in a plane M. From a fixed point (termed the centre of projection) outside of M draw lines to the various points of M until they intersect a second plane M'. Thus, every point P in M is associated with a definite point P' in M'. The operation of passing from a figure in M to the corresponding figure in M' is termed projection. Concretely, we may think of the centre of projection as a source of light and the figure in M' as the shadow of that in M.*

If we consider three points P_1, P_2, P_3 on a straight line in M, they are converted, by projection, into points P_1', P_2', P_3' on a straight line in M'. But in general the distances and also the ratios of distances will differ. In fact, three points have no invariant, since they may be converted into three points at arbitrarily assigned distances by a suitable projection. If, however, we take four points (on a straight line) it may be shown that, for any projection,

$$\frac{P_1P_3}{P_2P_3} : \frac{P_1P_4}{P_2P_4} = \frac{P_1'P_3'}{P_2'P_3'} : \frac{P_1'P_4'}{P_2'P_4'}.$$

In each member of this equation we have a combination of the distances between four points which is termed their cross ratio (anharmonic ratio). Hence the cross ratio of four collinear points is invariant with respect to projective transformation.

5. Let the figures considered be all the ellipses of a plane. With respect to displacement an ellipse has two invariants, the major and the minor axis. With respect to similitude transformation, there is one invariant, the ratio of the axes, or what is essentially the same, the eccentricity. Finally, in the projective theory there are no invariants, since one ellipse may be converted into any other (and even into any proper conic).

In this connection we may illustrate the notion of a covariant. The centre of an ellipse is a covariant with respect to displacement and magnification, but not with respect to projection. For if the plane containing an ellipse E and its centre C is displaced or magnified, so that ellipse E is converted into another ellipse E' and the point C is converted into a point C', then C' is necessarily the centre of E'; while under projection this is not the case. A similar result holds for the centre of gravity of any figure, plane or solid.

6. Another well-known type of transformation is that known as inversion. Take a fixed circle F with centre C and radius r, and suppose that any point P of the plane is converted into the point P' situated on the line CP, so that $CP \cdot CP' = r^2$. The points P, P' are then said to be inverse with respect to the circle F. By the inverse of a curve is meant the locus of the points inverse to the points of the curve. The collinear relation of points is no longer invariant, for a straight line (not passing through C) is converted into a circle. An arbitrary

* It is however necessary to include the ideal shadow formed by producing the rays away from M.

circle is converted into a circle, but the centre of the circle is not a covariant point. The most important property of the transformation is this: the angle at which any two curves intersect is equal to the angle at which the inverse curves intersect. Angles are invariant with respect to geometric inversion.

7. We pass now to a few simple examples of the general definition in No. 2, in which the objects and transformations are analytic instead of geometric.

Let the objects O be functions of any number of variables, and let the operations T performed on these functions be the permutation of the variables involved. A function written down at random, for example x^2+2yz, changes its form when say x and y are interchanged. There are exceptional functions, like $x^2+y^2+z^2$ and $xy+yz+xz$, which are not altered by interchanging the variables in any way, and are termed symmetric. The symmetric functions are invariant with respect to permutation of the variables.

In the differential calculus it is shown that the exponential function e^x has the property of being its own derivative. The only functions which are invariant with respect to the process of differentiation are in fact those of the form ae^x, where a is a constant. It is obvious that if the first derivative is equal to the original function, all the higher derivatives will also be equal to the function.

The trigonometric functions have a period of 2π or 360°. Such a function $f(x)$ is unaltered in value when x is replaced by $x+2\pi$. It is obvious that the double application of the operation, that is, the replacing of x by $x+4\pi$, will also leave $f(x)$ invariant. The periodic character thus involves the invariance of the function with respect to all the operations $(x, x+2k\pi)$ (this denotes the replacing of x by $x+2k\pi$), where k is any integer. We note here that if one of these operations, say that of adding $2k'\pi$ to the angle, is followed by another, say that of adding $2k''\pi$, the result is the same as the single operation of adding $2(k'+k'')\pi$, which is a member of the set. The set of operations thus possesses the essential property of a group.

8. In general, if an invariant is found with respect to certain operations, T_1, T_2, ..., the invariance also holds for all combinations of these operations. Adding these combinations to the original operations, a set is finally obtained with the group property; this is then termed the group generated by the given operations.

Thus, in connection with No. 6, since angles are unaltered by inversion with respect to any circle, it follows that they are unaltered by successive inversion with respect to a number of circles. The inversions themselves do not constitute a group; but the totality of combinations is the important group of circular transformations which are expressed analytically by the linear transformations of a complex variable and of its conjugate.

9. The general problem of the mathematical theory of invariants may now be restated as follows: Given any group of transformations, and any set of configurations (mathematical objects) which are converted into one another by these transformations, to find the properties of the configurations which remain unaltered. There are thus as many types of invariant theories as there are types of groups and types of configurations. The distinction according to groups is the more fundamental.

10. The relation between the concepts invariant and group is thus very intimate. Suppose that instead of assigning transformations and seeking invariants, the question is inverted: Given a property or a function, find the transformations which leave it invariant.

Thus, if space is to be deformed so as to leave the distance between every pair of points unaltered, the deformation must be simply a displacement. The totality of displacements forms a group; for if one displacement is followed by a second, the effect is the same as that due to a single displacement. In general the totality of transformations defined by one or more invariants is a group. Many groups are defined in this way.

11. In connection with any group this question may be asked: Given two configurations, is it possible to convert the one into the other by a transformation belonging to the assigned group? If this is the case, the configurations are said to be *equivalent* with respect to the group.

Thus, two figures are equivalent with respect to the displacement group when they are congruent; they are equivalent with respect to the similitude group when they are similar. The study of equivalence with respect to the projective group is the main object of projective geometry; its systematic analytic treatment depends upon the theory of algebraic forms considered below.

The importance of the notion of equivalence depends upon the fact that equivalent configurations necessarily have the same invariant functions and properties. Thus in studying the projective properties of (proper) conics, it is sufficient to consider the case of a circle. The circle may thus be taken as the *type* or *canonical form* of the class of conics.

The Theory of Algebraic Forms.

12. This part of modern algebra deals with the invariants of algebraic forms with respect to the group of linear transformations. It has been variously termed the theory of forms, the algebra of quantics, the algebra of linear transformations, the linear or projective invariant theory. Traces of the idea may be found in papers by Lagrange, Gauss and Cauchy; and simple results on quadric forms were given by G. Boole (1841); but the construction of the systematic theory begins with the memoirs of A. Cayley (1845–) and J. J. Sylvester* (1851–). The recent developments are due mainly to German and Italian mathematicians.

13. The objects considered are algebraic forms. A *form* or *quantic* is a rational integral homogeneous function of any number of variables. Forms are classified according to the number of variables and the degree in which they are involved. A *binary* form involves two variables; a *ternary*, three; a *quaternary*, four; in the general case of p variables the adjective p-ary is employed. The degree in which the variables enter is termed the *order* of the form;

*Most of the technical terms employed (including invariant, covariant, form) are due to Sylvester, who gloried in the title of "The Mathematical Adam."

we denote it in general by n. If n is one, the form is linear; if two, quadric (or quadratic); if three, cubic; if four, quartic (biquadratic); etc.

Thus the binary cubic form is

$$ax^3+bx^2y+cxy^2+dy^3,$$

where x, y are the variables and a, b, c, d the coefficients. It is usual, however, to distinguish the variables and the coefficients by subscripts, a notation which has the advantage of generality and symmetry; also binomial coefficients are introduced. Thus the above form is written

$$a_0x_1^3+3a_1x_1^2x_2+3a_2x_1x_2^2+a_3x_2^3.$$

The ternary quadric is

$$a_{11}x_1^2+a_{22}x_2^2+a_{33}x_3^2+2a_{23}x_2x_3+2a_{13}x_1x_3+2a_{12}x_1x_2.$$

The general binary form is

$$(1)\quad a_0x_1^n+\frac{n}{1}x_1^{n-1}x_2 +\frac{n(n-1)}{1\cdot 2}x_1^{n-2}x_2^2+\ldots+a_nx_2^n.$$

14. The group employed consists of the totality of linear transformations of the variables. A linear transformation from the original variables $x_1, x_2, \ldots x_p$ to the new variables $X_1, X_2, \ldots X_p$ is defined by p equations of the first degree, as follows:

$$\begin{aligned} x_1&=l_{11}X_1+l_{12}X_2+\ldots+l_{1p}X_p,\\ x_2&=l_{21}X_1+l_{22}X_2+\ldots+l_{2p}X_p,\\ &\ldots\ldots\ldots\ldots\ldots\ldots\\ x_p&=l_{p1}X_1+l_{p2}X_2+\ldots+l_{pp}X_p. \end{aligned}$$

The determinant

$$\Delta=|l_{ij}|,$$

whose elements are the p^2 coefficients in these equations, is termed the *modulus* of the transformation. It is assumed that Δ does not vanish; for in the latter case the X's cannot be expressed in terms of the x's, that is, the transformation is not reversible.

We shall deal mainly with binary variables and then employ the simpler notation

$$(2)\quad x_1=l_1X_1+m_1X_2,\quad x_2=l_2X_1+m_2x_2.$$

The modulus is $\Delta=l_1m_2-l_2m_1$.

15. When a linear transformation is carried out on a form, the latter is converted into a form of the same order containing the new variables. The coefficients of this transformed quantic depend of course upon the transformation employed. Thus if in the quadric

$$f\equiv a_0x_1^2+2a_1x_1x_2+a_2x_2^2$$

we make the substitution (2), the result is a new quadric,

$$F\equiv A_0X_1^2+2A_1X_1X_2+A_2X_2^2,$$

where

$$\begin{aligned} A_0&=l_1^2a_0+2l_1l_2a_1+l_2^2a_2,\\ A_1&=l_1m_1a_0+(l_1m_2+l_2m_1)a_1+l_2m_2a_2,\\ A_2&=m_1^2a_0+2m_1m_2a_1+m_2^2a_2. \end{aligned}$$

It is easy to verify that

$$A_0A_2-A_1^2=(l_1m_2-l_2m_1)^2(a_0a_2-a_1^2).$$

According to the general definition in No. 2, the function $a_0a_2-a_1^2$ is not an invariant function, since it is not equal to $A_0A_2-A_1^2$; but the relation $a_0a_2-a_1^2=0$ is invariant, since its fulfilment necessitates $A_0A_2-A_1^2=0$. This is sometimes expressed by saying that the function is a *relative* invariant.

It is usual, however, to modify somewhat the general definition as follows: A function of the coefficients of a quantic is said to have the invariant property when it is equal to the same function of the coefficients of the transformed quantic, except for a factor depending only upon the coefficients of the linear transformation. Thus if $\phi(a)$ is such a function, where a denotes the coefficients collectively, and if A denotes the coefficients in the new form, then

$$(3)\quad \phi(A)=M\phi(a),$$

where M depends only on the transformation coefficients.

All such functions can be expressed in terms of rational integral functions with the same property. These are termed simply invariants. Thus an *invariant* is a rational integral function of the coefficients with the property expressed by (3).

16. A *covariant* of a quantic differs from an invariant only in that it involves both the coefficients and the variables. Its defining property is expressed by

$$(3')\quad \phi(A, X)=M\phi(a, x).$$

Thus the binary cubic

$$a_0x_1^3+3a_1x_1^2x_2+3a_2x_1x_2^2+a_3x_2^3$$

has the covariant

$$(a_0a_2-a_1^2)x_1^2+(a_0a_3-a_1a_2)x_1x_2+(a_1a_3-a_2^2)x_2^2;$$

for when the cubic is linearly transformed, it is found that the corresponding expression

$$(A_0A_2-A_1^2)X_1^2+(A_0A_3-A_1A_2)X_1X_2+(A_1A_3-A_2^2)X_2^2,$$

built from the new coefficients and variables, reduces to the original expression multiplied by $(l_1m_2-l_2m_1)^2$.

17. Invariants and covariants are collectively termed concomitants or, more simply, *comitants*. We give now a few of their important general properties.

A comitant is homogeneous in the coefficients (a) and in the variables (x). Its dimension in the former is termed its degree (d); its dimension in the latter, its order (m). For an invariant, of course, $m=0$.

The factor M produced by the linear transformation is for every comitant an entire power of the modulus Δ. Hence

$$(4)\quad \phi(A, X)=\Delta^w\phi(a, x).$$

The exponent w is termed the *weight* of the comitant.

The proof of the first theorem depends on the use of linear transformations of the special type $x_1=\rho X_1$, $x_2=\rho X_2$; that of the second theorem depends on the group property of linear transformations and the fact that Δ is not factorable.

18. The weight w, order m, and degree d of any comitant of a binary n-ic are connected by the relation

$$2w=nd-m.$$

This holds in the example given in No. 16, where $n=3$, $m=2$, $d=2$, $w=2$.

Taking $m=0$ and n odd, we have the corollary. A binary form of odd order cannot have an invariant of odd degree.

When n is even, so is m. Hence a binary form of even order cannot have a covariant of odd order.

19. The preceding definitions and theorems may readily be extended to *simultaneous* comi-

tants, that is, invariants and covariants of two or more forms.

20. An important process for the formation of simultaneous comitants depends on this principle: If in an invariant $\phi(a_0, a_1, \ldots a_n)$ of a single form f, we substitute $a_0 + \kappa b_0$ for a_0, $a_1 + \kappa b_1$, for a_1, etc., and expand the result according to powers of κ, the first term is the original invariant $\phi(a)$, the coefficient of κ^d is the corresponding invariant $\phi(b)$ of a form g with coefficients $b_0, b_1, \ldots b_n$, and the remaining coefficients are simultaneous in variants of f and g.

For example, when this principle is applied to the invariant $a_0a_2 - a_1^2$ of a quadric $f = a_0x_1^2 + 2a_1x_1x_2 + a_2x_2^2$, we have

$$(a_0 + \kappa b_0)(a_2 + \kappa b_2) - (a_1 + \kappa b_1)^2 = a_0a_2 - a_1^2 + \kappa(a_0b_2 - 2a_1b_1 + a_2b_0) + \kappa^2(b_0b_2 - b_1^2).$$

It follows that $a_0b_2 - 2a_1b_1 + a_2b_0$ is a simultaneous invariant of f and $g = b_0x_1^2 + 2b_1x_1x_2 + b_2x_2^2$.

The coefficient of the first power of κ, by Taylor's theorem, is

$$b_0\frac{\partial\phi}{\partial a_0} + b_1\frac{\partial\phi}{\partial a_1} + \ldots + b_n\frac{\partial\phi}{\partial a_n}.$$

Hence if the operation $b_0\frac{\partial}{\partial a_0} + b_1\frac{\partial}{\partial a_1} + \ldots + b_n\frac{\partial}{\partial a_n}$ is applied to an invariant of a single form, the result is an invariant of two forms. The operation is known as the *Aronhold process.*

21. In the domain of simultaneous comitants the distinction between invariants and covariants may be said to disappear. All the covariants of a form f may be obtained from the simultaneous invariants of f and a linear form $u_1x_1 + u_2x_2$ by the substitution of x_2 for u_1 and $-x_1$ for u_2.

22. *Geometric Interpretation.*— If a binary form f of nth order is equated to zero, the resulting equation, by the fundamental theorem of algebra, determines n values of the ratio $x_1 : x_2$. Taking $x_1 : x_2$ as homogeneous coordinates of a point on a straight line, we thus obtain a definite set of n points corresponding to the form f. Conversely, if a set of n points is given, the form f is determined (except for a numerical factor).

Linear transformation of x_1, x_2 has the same effect upon the points of the line as the projection of the given line upon a second followed by the displacement of the second line upon the first. Hence an invariant of f equated to zero represents a projective relation between the corresponding n points, that is, a relation not altered by the process of projection. Similarly, a covariant of order m represents a set of m points projectively related to points defined by f.

Thus, the vanishing of the invariant $a_0a_2 - a_1^2$ of a quadric form means that the two root points coincide. Again, the vanishing of $a_0b_2 - 2a_1b_1 + a_2b_0$, derived in No. 21, means that the pairs of points represented by the two quadrics are situated harmonically.

The interpretation often suggests the invariant character of complicated algebraic functions. For example, the *resultant* of two equations, $f = 0$, $g = 0$ (that is, the expression which vanishes when and only when the equations have a common root), is a simultaneous invariant of f and g. The condition that the equation $f = 0$ shall have equal roots leads to an invariant termed the *discriminant* of f.

23. *Absolute Invariants.*— By considering fractional instead of integral functions of the coefficients, it is possible to obtain *absolute invariants,* that is, functions which are unaltered by linear transformation. The factor M in (3) is then unity. An absolute invariant is necessarily the ratio of two (relative) invariants having the same weight. We give an example in connection with the form of fourth order. Here there are two invariants I and J with weights 3 and 2 respectively. Linear transformation affects them as follows: $I' = \Delta^3 I$, $J' = \Delta^2 J$. Hence $I'^3/J'^2 = I^3/J^2$. That is, I^3/J^2 is an absolute invariant.

Geometrically, every absolute invariant of any number of forms is expressible in terms of cross ratios of the corresponding points.

24. *The Symbolic Notation.*— The most powerful method for attacking the general problem of our subject, the determination of all the comitants of any number of forms and their interrelations, is the so-called *symbolic* method. The origin of the method is to be found in Cayley's hyperdeterminants (1845), but the symbolic notation itself is due to Aronhold (1859). The general theory was developed by Clebsch and Gordan (1870–).

A binary form of nth order is represented by the nth power of a linear form,

$$f = (a_1x_1 + a_2x_2)^n.$$

Here the a's are merely symbols which have a real meaning only in the combinations

$$a_1^n = a_0,\ a_1^{n-1}a_2 = a_1,\ a_1^{n-2}a_2^2 = a_2,\ \ldots,\ a_2^n = a_n.$$

The Roman letters denote real coefficients and the Greek letters symbolic coefficients. The latter were termed *umbrae* (shadows of quantities) by Sylvester.

A combination of a's of dimension $< n$ has no real meaning. On the other hand, if the dimension is a multiple of n, there are several corresponding real quantities. Thus $a^{m-2}a_1^2$ represents both a_0a_2 and a_1^2. This ambiguity is removed by introducing several equivalent sets of umbral quantities, each entering in precisely the nth dimension. We abbreviate by writing $a_1x_1 + a_2x_2 = a_x$, $\beta_1x_1 + \beta_2x_2 = \beta_x$, etc. The given form is then

$$f = a_x^n = \beta_x^n = \gamma_x^n, \text{ etc.}$$

The fundamental theorem is as follows: Every comitant of binary forms f is expressible symbolically as a combination of determinants of the type $(a\beta) = a_1\beta_2 - a_2\beta_1$ and linear factors of the type $a_x = a_1x_1 + a_2x_2$. In the case of invariants, only the determinants are involved. Conversely, all combinations of these two types (in which each set of symbols is involved in the proper dimension) represent comitants.*

Thus the quadric $f = a_x^2 = \beta_x^2$ has the invariant $(a\beta)^2$. Expanding, we have

$$(a_1\beta_2 - a_2\beta_1)^2 = a_1^2\beta_2^2 - 2a_1a_2\beta_1\beta_2 + a_2^2\beta_1^2 = a_0a_2 - 2a_1a_1 + a_2a_0,$$

which is simply twice the discriminant $a_0a_2 - a_1^2$.

25. *Transvectants.*—Among the comitants of two forms, $f = a_x^n$, $g = \beta_x^m$ (here a and β are non-equivalent symbols), those represented by $(a\beta)^\kappa a_x^{n-\kappa}\beta_x^{m-\kappa}$ are of special importance, since they are of the first degree in each set of coefficients. They are termed the *transvectants* of f and g and are denoted by $(f, g)^\kappa$. Gordan has shown that all comitants may be derived by the repeated application of the process of transvection.

The first transvectant of two forms is termed their *Jacobian;* its non-symbolic value is $\frac{\partial f}{\partial x_1}\frac{\partial g}{\partial x_2} - \frac{\partial f}{\partial x_2}\frac{\partial g}{\partial x_1}$. The transvectant $(f, f)_2$ is termed the *Hessian* of f; its non-symbolic value is $\frac{\partial^2 f}{\partial x_1^2}\frac{\partial^2 f}{\partial x_2^2} - \left(\frac{\partial^2 f}{\partial x_1 \partial x_2}\right)^2$.

26. *Complete Systems.*—In general, a set of forms has an infinite number of comitants. Thus any entire power of a comitant, or a product of powers of two comitants, is also a comitant. It is evident, however, that there cannot exist an infinite number of algebraically independent comitants, since all are functions of a finite number of coefficients and variables. The following result is fundamental in the systematic theory: For a given set of forms there exists a finite number of comitants such that every comitant of the forms is a rational integral function of the selected comitants. The latter constitute the *complete system* of the given forms.

The proof was first given by Gordan (1870) by means of the symbolic method. It has since been simplified and generalized by numerous investigators — in particular, Hilbert.

27. We now give the complete systems for the forms of order 1, 2, 3, 4:

Linear form. No invariant; the only covariant is the given form $f = a_x$.

Quadric form. One invariant (the discriminant) $D = (a\beta)^2$; one covariant $f = a_x^2$.

Cubic form. The only invariant is the discriminant $R = (a\beta)^2(a\gamma)\ (\beta\delta)\ (\gamma\delta)^2$; in addition to $f = a_x^3$, there are two covariants, $H = (a\beta)^2a_x\beta_x$ (the Hessian of f) and $Q = (a\beta)^2(a\gamma)\beta_x\gamma_x^2$ (the Jacobian of f and H).

Quartic form. Two invariants, $I = (a\beta)^4$, $J = (a\beta)^2(\beta\gamma)^2(\gamma a)^2$; three covariants, the given form $f = a_x^4$, its Hessian $H = (a\beta)^2a_x^2\beta_x^2$, and the Jacobian of f and H, namely, $T = (a\beta)^2(a\gamma)a_x\beta_x^2\gamma_x^3$.

Every invariant of the quartic form is thus a rational integral function of I and J; every comitant is a rational integral function of I, J, f, H, T.

28. The systems given are *irreducible;* that is, no member of a system can be expressed as a rational integral function of the other members of the system.

Complete irreducible systems have been calculated for single forms up to the order 10 and for pairs of forms up to the order 4. The system of the quintic contains 23 members.

While the finiteness of the system is assured, no general formula for the exact number of irreducible comitants is known.

29. *Ternary Forms.*— Many of the results stated for the binary case apply with little change to ultrabinary forms. There are, however, certain aspects of the general theory which are disguised when only the binary case is studied.

Consider a ternary form $f(x_1, x_2, x_3)$ of nth order. (The symbolic representation is a_x^n, where $a_x = a_1x_1 + a_2x_2 + a_3x_3$). If x_1, x_2, x_3 are taken as the homogeneous co-ordinates of a point in a plane, the equation $f = 0$ defines a curve of nth order. The vanishing of an invariant denotes a projective property of the curve. A covariant defines a curve which is projectively related to the original curve.

The principle of duality suggests the introduction of line co-ordinates u_1, u_2, u_3. When the x's undergo a linear transformation, the u's undergo another linear transformation, which is said to be *contragredient* to the first. A function involving the u's and having the invariant property is termed a *contravariant* of f. Geometrically it represents a curve considered as the envelope of its tangent lines. A *mixed* comitant is one involving both point co-ordinates and line co-ordinates; geometrically it defines a so-called *connex.*

The complete system of the ternary quadric $f = a_x^2$ consists of the covariant f, the invariant $D = (a\beta\gamma)^2$, the contravariant $F = (a\beta u)^2$, and the so-called identical form u_x. Here $(a\beta\gamma)$ represents a determinant of third order $(a_1\beta_2\gamma_3)$. Geometrically, $f = 0$ represents a conic considered as a point locus, $F = 0$ represents the same conic regarded as line envelope, and $D = 0$ denotes that the conic degenerates to a pair of straight lines.

30. *Quaternary Forms.*— Here the essentially new feature is that in addition to point co-ordinates (x_1, x_2, x_3, x_4) and the dual plane co-ordinates (u_1, u_2, u_3, u_4), it is necessary to consider line co-ordinates $(p_{12}, p_{13}, p_{14}, p_{34}, p_{42}, p_{23})$. Comitants may contain, besides the coefficients of the given form, any combination of these types of variables. Little advance has yet been made in the complete treatment of even the simpler cases.

31. Gordon's method for proving the existence of a complete system applies only to binary forms. The proof for forms of any kind (including multiple forms containing two or more sets of variables) was first given by Hilbert (1890). The basis of his method is the following theorem, which has many important applications:

In any assemblage containing an infinite number of forms it is possible to select a finite number of members $F_1, F_2, \ldots, F_r$ so that every member can be written $F = P_1F_1 + P_2F_2 + \ldots + P_rF_r$, where the P's are forms not belonging necessarily to the given assemblage.

Other Invariant Theories.

32. *Special Linear Transformations.*— Forms have been treated with respect to linear transformations of special type. Thus the transformations $x_1 = aX_1 + \beta$, $y_1 = aY_1$ lead to the so-called *seminvariants* of binary forms.

Again, the formulas for passing from one system of rectangular co-ordinates to another,

$$(5) \qquad x = X\cos\theta - Y\sin\theta + h, \quad y = X\sin\theta + Y\cos\theta + k,$$

constitute a special linear group. Invariants with respect to this group are termed Cartesian or metric or orthogonal. In the case of the conic $ax^2 + bxy + cy^2 + dx + ey + f = 0$, there are three such invariants, $a + c$, $b^2 - 4ac$, and the discriminant. The latter is the only one which is invariant in the projective theory.

* Sylvester observed certain formal analogies between this symbolism and that employed in chemistry, and developed a so-called chemico-algebraic theory. Consult Grace and Young, 'Algebra of Invariants,' (Cambridge 1903. p 366).

If $a+c=0$, the conic is a rectangular hyperbola; if $b^2-4ac=0$, it is a parabola.

For any number of variables the linear transformations which leave a given quadric form unchanged constitute a type of group which arises in many applications (line and circle geometries, geometry on a quadric surface, etc.).

33. The general method of finding the invariants of any continuous group involving a finite number of parameters is due to Sophus Lie. An r parameter group is generated by r independent infinitesimal transformations; these determine a set of r partial differential equations whose solutions are the invariant functions.

34. A *differential invariant* is one that contains the derivatives of the variables. Thus for the group (5) the expression $\frac{y''}{(1+y')^2}$ is a differential invariant. It represents in fact the curvature of an arbitrary curve at a point; this is obviously independent of the system of axes to which the curve is referred.

35. Special theories of invariants have been constructed in connection with *differential equations*. Thus an ordinary linear equation,

$$\frac{d^ny}{dx^n}+p_1(x)\frac{d^{n-1}y}{dx^{n-1}}+\ldots+p_n(x)=0,$$

is converted into an equation of the same kind by the substitution $x=\varphi(X)$, $y=Y\psi(X)$. The totality of substitutions here forms an infinite continuous group, since ϕ and ψ are arbitrary functions. By an invariant of the equation is meant a function of the coefficients $p_1, p_2 \ldots$ and their derivatives, which retains its value (except perhaps for a factor depending on the transformation) when formed from the coefficients of the new equation.

36. *Differential Forms.*—In the theory of surfaces the distance between two consecutive points of the surface is given by the formula $ds^2=E(u,v)du^2+2F(u,v)\ du\ dv+G(u,v)dv^2$. The second member is a binary quadratic differential form. Such forms possess a theory of invariants with respect to arbitrary change of variables. Any change is expressed by $u=\phi(U,V)$, $v=\psi(U,V)$, where ϕ, ψ are arbitrary functions. The simplest example of an invariant is the expression, depending on E, F, G and their partial derivatives, which represents the Gaussian curvature.

37. *Arithmetical Theory of Forms.*—In this theory, inaugurated by Gauss, the coefficients and variables involved are supposed to be whole numbers. Attention has been confined mainly to the binary quadratic $ax^2+2bxy+cy^2$. The transformations are defined by $x=aX+\beta Y$ $y=\gamma X+\delta Y$, where the coefficients α, β, γ, δ are integers such that $\alpha\delta-\beta\gamma=0$. In this case then, the group is discontinuous.

38. *Automorphic Functions.*—Such discontinuous groups arise also in the theory of functions. Thus in No. 7 it was seen that the trigonometric functions are unaltered by the substitutions $x=X+2k\pi$. Similarly, a doubly periodic function (of a complex variable) is invariant with respect to $z=Z+k_1w_1+k_2w_2$, where w_1, w_2 are the given periods and k_1, k_2 are arbitrary integers. The modular function is invariant with respect to the linear group $z=(aZ+\beta)/(\gamma Z+\delta)$, where $\alpha, \beta, \gamma, \delta$ are integers such hat $\alpha\delta-\beta\gamma=1$. The problem of finding all functions which admit an infinite discontinuous group of linear transformations is one of the most important in recent investigation. Such functions are termed *automorphic*. They have been classified by Poincaré into Fuchsian and Kleinian according as the defining group involves real or complex coefficients.

EDWARD KASNER,
Professor in Mathematics, Columbia University.

INVASION, the entry into a country by a public enemy. As early as 1795 Congress provided by law for protection against the invasion of the United States by any foreign nation or Indian tribe. The act made it lawful whenever there should be an invasion, or imminent danger of one, for the President to call out such number of the militia of the State or States convenient to the place of invasion as he might think necessary to repel it. This, strengthened in some respects by amendments, has been in force ever since. An invasion has usually all the elements of war, and the invaders may be dealt with as persons at war with the country invaded, in accordance with usages of warfare without the declaration of war by Congress. The Supreme Court of the United States has decided that a State is invaded when there is a domestic rebellion within its territory, and that the same rules of law may be enforced as in the case of an invasion by external foes. This decision practically abolishes all distinction between invasion and insurrection, and the same rules which furnish a remedy for invasion can be applied in the suppression of an insurrection or local rebellion. In case the State militia is not sufficiently strong, or not easily available, the standing troops of the United States may be ordered out by the President, if indeed it be necessary to call upon the State troops before resorting to the regular troops of the United States. It is not necessary that actual armed violence shall be resorted to in order to constitute insurrection. Any combination of persons too powerful to be suppressed by the ordinary course of judicial proceedings is tantamount to insurrection, and warrants the use of the effective measures provided for by law for its suppression.

As regards the rights of the invader many rules have been laid down, carefully distinguishing between invasion and conquest, especially with respect to private and public property. It is now held that public money, military stores and public buildings with their contents are lawful sources of plunder, and telegraph and railway property may be used as needs require. The unwarranted burning of the Capitol and other public buildings in Washington by the British in 1814; the removal of the Palatine libraries during the Thirty Years' War; the confiscation of the astronomical instruments in the Observatory of Peking by the Germans during the operations of the Allies against the Chinese capital — all these were in direct violation of the accepted rules of invasion. The levying of supplies, labor, forage, transportation facilities, etc., upon the native people is strictly within the lawful confines of invasion; for example, during the wars of Frederick the Great, both the Austrians and the Prussians were mainly supported by these enforced contributions of supplies. Napoleon was probably the greatest exponent of the belief that a war should support itself, either during the conflict, or by imposing a large indemnity, or both; hence we see that he exacted of Prussia, after the battle of Jena, more than a hundred million francs, and Spain was forced during the Peninsular War to pay a similar amount. The pillage of private property is prohibited, but should the owners give aid to their country, the property may be sold at the discretion of the invading general.

INVENTION OF THE CROSS, a festival held in honor of the finding of the true cross, on which Christ was crucified, by the Empress Helena A.D. 316, on Mount Calvary, celebrated on 3 May. Since 1895 the festival is called «Ritrovamento» as celebrating the refinding of the cross, which was identified and buried in the 1st century by Empress Protonice. See CROSS.

INVENTIONS. The progress of the world in its numerous vast industries and arts has been founded, to a very large extent, upon inventions and discoveries and their subsequent development. Under the American patent law and system, inventors all over the world are stimulated to make public their inventions by reason of receiving in exchange a monopoly in the form of a patent on the invention for a period of 17 years. The remarkable increase in the number of protected inventions is shown by the records of the United States Patent Office, as follows: At the end of the first year (1790) 3 patents were issued. In the year ending 1902, 27,136 patents were granted; in 1916, 43,970. The total number of patents issued from April 1790 to the end of 1918 was over 1,125,000. Carriages and wagons have been the subject of the greatest number of United States patents, nearly 40,000.

An invention is recognized to be any new or useful mechanical contrivance or article, method, discovery, composition of matter, or system not previously known or used, or any improvement on any known machine, art, method or system. Below is given in chronological order a list of important inventions and discoveries beginning with the 16th century, with the title of the invention, the year it was made, the name of the inventor and his nativity:

INVENTIONS	Date	Inventor	Nativity
Discoveries of Electrical Phenomena.. Won the title of "founder of the science of electricity."	1560–1603	William Gilbert	England
Screw printing-press	1620	Blaew	Germany
Spirally grooved rifle barrel	1620	Koster	England
Iron furnaces	1621	Lord Dudley	England
The use of steam.... The first authentic reference in English literature to the use of steam in the arts.	1630	David Ramseye	England
Bay Psalm Book, first book published in the Colonies	1640		Mass.
Barometer	1643	Torricelli	Italy
Steam engine, atmospheric pressure	1663	Thomas Newcomen	England
Machine for generating electricity	1681–86	Otto von Guericke	Germany
First paper mill in America	1690	William Rittenhouse	Penna.
First steam engine with a piston	1690	Denys Papin	France
The manufacture of plate glass established	1695		France
First to discover difference between electric conductors and insulators	1696–1736	Stephen Gray	England
The first practical application of the steam engine	1702	Thomas Savery	England
First newspaper in America *Boston News Letter*	1704	John Campbell	Mass.
First to produce electric spark	1708–1716	Dr. J. Wall	England
Thermometer	1709	Fahrenheit	Danzig
Electrometer, the well-known pith ball	1718–1772	John Cantor	England
The "Franklin" printing-press	1725	Benj. Franklin	Utd.States
Stereotyping	1725	William Ged	Scotland
Electrical glass plate machine	1727–1772	Martin de Planta	France
First to discover that electricity is of two kinds	1733–39	Cisternay du Fay	France
Flying shuttle in weaving	1733	John Kay	England
Rotary 3-color printing-press (Multi-Color)	1743	Platt & Keen	England
Electric or Leyden jar	1745	Kleist	Germany
Substitution of coke for coal in melting iron	1750	Abraham Darby	England
Lightning conductor	1752	Benj. Franklin	Utd.States
Spinning jenny	1763	James Hargreaves	England
Piano forte, played in public in England in	1767		England
Drawing rolls in a spinning machine..	1769	Richard Arkwright	England
The introduction of the "Hollander" or beating engine for pulping rags in the manufacture of paper	1773		
The mule spinner	1774	Samuel Crampton	England
Cut nails	1775	Jeremiah Wilkinson	Utd.States
Circular wood saw	1777	Miller	England
Embryo bicycle	1779	Branchard & Magurier	France
Steam engine, the basis of the modern engine	1782	James Watt	Scotland
Gas balloon	1783	J. E. & J. M. Montgolfier	France
Puddling iron	1783–84	Henry Cort	England

INVENTIONS	Date	Inventor	Nativity
Plow, with cast iron mold board, and wrought and cast iron shares	1784	James Small	Scotland
Power loom	1785	James Cartwright	England
First steamboat in the United States	1786	John Fitch	Utd. States
Steam road wagon (First automobile)	1787	Oliver Evans	Utd. States
Grain threshing machine	1788	Andrew Meikle	England
Uranium discovered	1789	Klaproth	Germany
Hobby-horse, forerunner of bicycle	1790		England
Rotary steam power printing-press, the first idea of	1790	Wm. Nicholson	England
Wood planing machine	1791	Samuel Bentham	England
Power platen printing press	1791	I. Treadwell	Utd.States
Gas first used as an illuminant	1792	Wm. Murdoch	England
Cotton gin	1794	Eli Whitney	Utd. States
Art of lithography	1796	Alois Senefelder	Germany
Machine for making continuous webs of paper	1800	Louis Robert	France
Steam coach	1801	Richard Trevithick	England
Wood mortising machine	1801	M. J. Brunel	England
Pattern loom	1801	M. J. Jacquard	France
First fireproof safe	1801	Richard Scott	England
Steamboat on the Clyde, *Charlotte Dundas*	1802	William Symington	England
First photographic experiments	1802	Wedgewood & [Davy	England
Planing machine	1802	J. Branch	England
The application of steam to the loom	1803	William Horrocks	England
Steel pen	1803	Wise	England
Steam locomotive on rails	1804	Richard Trevithick	England
Application of twin screw propellers in steam navigation	1804	John Stevens	Utd. States
Process of making malleable iron castings	1804	Lucas	England
First life preserver	1805	John Edwards	England
Electro-plating	1805	Luigi Brugnatelli	Italy
Knitting machine, the latch needle in the	1806	Jeandean	France
Steamboat navigation on the Hudson River	1807	Robert Fulton	Utd. States
Percussion or detonating compound	1807	A. J. Forsyth	Scotland
First street gas lighting in England	1807	F. A. Winsor	England
Band wood saw	1808	Newberry	England
Barium, strontium and calcium	1808	Sir Humphry Davy	England
Polarization of light from reflection	1808	E. L. Malus	France
Voltaic arc	1808	Sir Humphry Davy	England
First steamboat to make a trip to sea, the *Phœnix*	1808	John Stevens	Utd. States
Homeopathy introduced	1810	S. C. F. Hahnemann	Germany
Revolving cylinder printing-press	1810	Frederick Koenig	Germany
Breech-loading shotgun	1811	Thornton & Hall	Utd. States
Storage battery	1812	J. B. Ritter	Germany
Dry pile (prototype of dry battery)	1812	Zamboni	
First practical steam rotary printing press, paper printed on both sides	1814	Frederick Koenig	Germany
First locomotive in Scotland	1814	George Stephenson	England
First circular wood saw made in this country	1814	Benjamin Cummings	Utd. States
Heliography	1814	Jos. N. Niepce	France
Discovery of cyanogen	1814	Gay Lussac	France
Kaleidoscope	1814	Sir David Brewster [Davy	England
Miner's safety lamp	1815	Sir Humphry	England
Seidlitz powder	1815		
Dry gas meter	1815	S. Clegg	England
Morphine, first organic alkaloid known	1816	Sertüner	Germany
Knitting machine	1816	Brunel	England
"Draisine" bicycle	1816	Baron von Drais	Germany
"Columbian" press, elbowed pulling bar, number of impressions per hour, 200	1817	George Clymer	Utd. States
Stethoscope	1819	Laënnec	France
Electro-magnetism discovered	1819	H. C. Oersted	Germany
Lathe for turning irregular wood forms	1819	Thomas Blanchard	Utd. States
The theory of electro-dynamics first propounded	1820	Andre Ampère	France
Quinine	1820	Pelletier & Caventon	France
Electroscope	1820	Bohenberg	Germany
The conversion of the electric current into mechanical motion	1821	Michael Faraday	England
Galvanometer	1822	Schweigger	Germany
Multi-color printing	1822	P. Force	Utd. States
Calculating machine	1822	Charles Babbage	England
Silicon	1823	James Berzelius	Switzerl'd
Discovery of thermo-electricity	1823	Prof. Seebeck	England
Liquefaction and solidification of gas	1823	Michael Faraday	England
Water gas, production of	1823	Ibbetson	England
Portland cement	1825	Joseph Aspdin	England
First passenger railway, opened between Stockton and Darlington, England	1825		
Electrical spur wheel	1826	Barlow	England
Bromine	1826	M. Balard	France
First railroad in United States, near Quincy, Mass	1826		
The law of galvanic circuits formulated	1827	George S. Ohm	Germany
Friction matches	1827	John Walker	Utd.States
The reduction of aluminium	1827	Frederich Wohller	Germany
Law of electrical resistance	1827	George S. Ohm	Germany
Improved rotary printing-press London *Times*, 5,000 impressions per hour	1827	Cowper & Applegarth	England
Hot air blast for iron furnaces	1828	J. B. Neilson	Scotland
Wood planing machine	1828	William Woodworth	Utd. States
Tubular locomotive boiler	1828	Séquin	France
Prism for polarized light	1828	Nicol	England
Spinning ring frame	1828	John Thorp	England
Type casting and setting machine	1828	Wm. Church	Utd. States
The "Washington" hand printing press	1829	Samuel Rust	Utd. States
Papier-mache stereotyping	1829	Genoux	France
First steam locomotive in United States, "Stourbridge Lion"	1829		
Double fluid galvanic battery	1829	A. C. Becquerel	France
Magnesium	1829	Adam Bussey	France
First portable steam fire engine	1830	Brathwaite & Ericsson	England

INVENTIONS	Date	Inventor	Nativity
Magneto-electric induction	1831	Michael Faraday	England
Chloroform	1831	G. J. Guthrie	Scotland
First conception of electric telegraph	1832	Prof. S. F. B. Morse	Utd. States
First magneto-electric machines	1832	Saxton	Utd. States
Rotary electric motor	1832	Wm. Sturgeon	England
Chloral-hydrate	1832	Justus von Liebig	Germany
Locomotive, "Old Ironsides" built	1832	M. W. Baldwin	Utd. States
Link-motion for locomotives	1832	Sir Henry James	England
Adoption of steam whistle for locomotives	1833	George Stephenson	England
Reciprocating sawtooth cutter within double guard fingers for reapers	1833	Obed Hussey	Utd. States
"McCormick" reaper	1834	Cyrus H. McCormick	Utd. States
Rotary electric motor	1834	M. H. Jacobi	Russia
Carbolic acid discovered	1834	Runge	Germany
Horse shoe machine	1835	H. Burden	Utd. States
Constant electric battery	1836	J. P. Daniell	England
Acetylene gas discovered	1836	Edmund Davy	England
The revolver; a device "for combining a number of long barrels so as to rotate upon a spindle by the act of cocking the hammer."	1836	Samuel Colt	Utd. States
The screw applied to steam navigation	1836 / 1841	John Ericsson	Utd. States
The galvanizing of iron	1837	Henry Craufurd	England
Indicator-telegraph	1837	Cooke & Wheatstone	England
Photographic carbon printing	1838	Mungo Ponton	France
Babbitt metal	1839	Isaac Babbitt	Utd. States
Vulcanization of rubber	1839	Charles Goodyear	Utd. States
The first boat electrically propelled	1839	Jacobi	Germany
Daguerreotype	1839	Louis Daguerre	France
First to produce a direct photographic positive in the camera by means of highly polished silver surfaced plate exposed to the vapors of iodine and subsequent development with mercury vapor.			
Making photo-prints from paper negatives	1839	Fox Talbot	England
(First production of positive proofs from negatives).			
Photographic portraits. (Daguerreotype process)	1839	Draper & Morse	Utd. States
Pneumatic caissons	1841	M. Triger	France
Pianoforte automatically played	1842	M. Seytre	France
Steam hammer	1842	James Nasmyth	Scotland
Typewriting machine	1843	Charles Thurber	Utd. States
First telegram sent	1844	Prof. S. F. B. Morse	Utd. States
The use of nitrous oxide gas as an anæsthetic	1844	Dr. Horace Wells	Utd. States
The electric arc light (gas retort carbon in a vacuum)	1844	Léon Foucault	France
Automatic adjustment of electric arc light carbons	1845	Thomas Wright	England
Double cylinder printing-press	1845	R. Hoe & Co.	Utd. States
Pneumatic tire	1845	R. W. Thompson	England
Sewing machine	1846	Elias Howe	Utd. States
Suez Canal started	1846	De Lesseps	France
Ether as an anæsthetic	1846	Dr. Morton	Utd. States
Artificial limbs	1846		
Gun cotton	1846	Schönbein	Germany
First pianoforte keyboard player	1846	Debain	France
Chloroform in surgery	1847	Dr. Simpson	Scotland
Nitro-glycerine	1847	Sobrero	Scotland
Time-lock	1847	Savage	Utd. States
Hoe's type-revolving cylinder printing-press	1847	Richard M. Hoe	Utd. States
Match-making machinery	1848	A. L. Dennison	Utd. States
Breech gun-lock, interrupted thread	1849	Chambers	Utd. States
Magazine gun	1849	Walter Hunt	Utd. States
Steam pressure gauge	1849	Bourdon	France
Lenticular stereoscope	1849	Sir David Brewster	England
Latch needle for knitting machine	1849	J. T. Hibbert	Utd. States
"Corliss" engine	1849	G. H. Corliss	Utd. States
Printing-press, curved plates secured to a rotating cylinder	1849	Jacob Worms	France
Mercerized cotton	1850	John Mercer	England
Collodion process in photography	1850	Scott Archer	England
American machine-made watches	1850		Utd. States
Electric locomotive	1851	Dr. Page	Utd. States
Self-raker for harvesters	1851	W. H. Seymour	Utd. States
Gordon job printing press	1851	Geo. P. Gordon	Utd. States
Breach loading rifle	1851	Maynard	Utd. States
Icemaking machine	1851	J. Gorrie	Utd. States
The Rhumkorff coil	1851	Rhumkorff	Germany
Fire-alarm telegraph	1852	Channing & Farmer	Utd. States
Reticulated screen for half-tone photographic printing	1852	Fox Talbot	England
Soda process of making pulp from wood	1853	Watt & Burgess	Utd. States
Laws of magneto-electric induction	1853	Michael Faraday	England
Laws of electrostatics	1853	Michael Faraday	England
Electrolysis	1853	Michael Faraday	England
Duplex telegraph	1853	Gintl	Austria
First efficient type-setting machine	1853	W. H. Mitchell	Utd. States
Photographic roll films	1854	Melhuish	England
Diamond rock drill	1854	Herman	Utd. States
Four motion feed for sewing machines	1854	A. B. Wilson	Utd. States
Magazine firearm	1854	Smith & Wesson	Utd. States
Fat decomposed by water or steam at high temperature, since largely used in soap making	1854	R. A. Tilghman	Utd. States
Safety matches	1855	Lundstrom	Sweden
Iron-clad floating batteries first used in Crimean War	1855		
Cocaine	1855	Gaedeke	Germany
Process of making steel, blowing air through molten pig-iron	1855	Sir Henry Bessemer	England
Dryplate photography	1855	J. M. Taupenot	
Bicycle	1855	Ernst Michaux	France
Sleeping car	1856	Woodruff	Utd. States
Aniline dyes	1856	Perkins	England
Printing machine for the blind (contains elements of the present typewriting machine)	1856	Alfred E. Beach	Utd. States
Regenerative furnace	1856	Wm. Siemens	England
Refining engine in paper pulp making	1856	T. Kingsland	Utd. States
Coal-oil first sold in the United States	1857	Stout & Hand	Utd. States

INVENTIONS	Date	Inventor	Nativity
First seagoing iron-clad war vessel, the *Gloire*	1857		France
Ground wood pulp	1858	Henry Voelter	Germany
Inclined elevator and platform in the reaper	1858	J. S. Marsh	Utd. States
Cable car	1858	E. A. Gardner	Utd. States
Breech loading ordnance	1858	Wright & Gould	Utd. States
Feed injector for boilers	1858	Giffard	France
Storage or secondary battery	1860	Gaston Planté	France
Singing telephone	1860	Philip Reis	Germany
Ammonia absorption ice machine	1860	F. P. E. Carré	France
Improved stereotyping process	1861	Charles Craske	Utd. States
Shoe sewing machine	1861	George McKay	Utd. States
Driven well, a tube with a pointed perforated end driven into the ground	1861	Col. N. W Green	Utd. States
Passenger elevator	1861	E. G. Otis	Utd. States
Barbed wire fence introduced	1861		Utd. States
Calcium carbide produced	1862	Frederich Woehler	Germany
Revolving turret for floating battery	1862	Theodore Timby	Utd. States
First iron-clad steam battery *Monitor*	1862	John Ericsson	Utd. States
Gatling gun	1862	Dr. R. J. Gatling	Utd. States
Smokeless gunpowder	1863	J. F. E. Schultze	Prussia
Pneumatic pianoforte player (regarded as first to strike keys by pneumatic pockets)	1863	M. Fourneaux	France
Explosive gelatine	1864	A. Nobel	Sweden
Rubber dental plate	1864	J. A. Cummings	Utd. States
Automatic grain binding device	1864	Jacob Behel	Utd. States
Process of making fine steel	1865	Martin	Utd. States
Antiseptic surgery	1865	Sir Joseph Lister	England
Web-feeding printing press	1865	William Bullock	Utd. States
Automatic shell ejector for revolver	1865	W. C. Dodge	Utd. States
The Atlantic cable laid	1866	Cyrus W. Field	Utd. States
Open-hearth steel process	1866	Siemens-Martin	England
Compressed air rock drill	1866	C. Burleigh	Utd. States
Torpedo	1866	Whitehead	Utd. States
Dynamo electric machine	1866	Wilde	England
Sulphite process for making paper pulp from wood	1867	Tilghman	Utd. States
Disappearing gun carriage	1868	Moncrief	England
First practical typewriting machine	1868	C. L. Sholes	Utd. States
Dynamite	1868	A. Nobel	Sweden
Oleomargarine	1868	H. Mege	France
Water heater for steam fire engine	1868	W. A. Brickell	Utd. States
Sulky plow	1868	B. Slusser	Utd. States
Railway air brake	1869	George Westinghouse	Utd. States
Tunnel shield (operated by hydrauiic power)	1869	Alfred E. Beach	Utd. States
A curved spring tooth harrow	1869	David L. Garver	Utd. States
Dynamo-electric machine	1870	Gramme	France
Celluloid	1870	J. W. & Isaac Hyatt	Utd. States
Rebounding gun-lock	1870	L. Hailer	Utd. States
The Goodyear welt shoe-sewing machine	1871	Goodyear	Utd. States
Photographic gelatino bromide emulsion (basis of present rapid photography)	1871	R. L. Maddox	England
Continuous web printing-press	1871	Hoe & Tucker	Utd. States
Grain binder	1871	S. D. Locke	Utd. States
Compressed air rock drill	1871	S. Ingersoll	Utd. States
Positive motion weaving loom	1872	J. Lyall	Utd. States
Theory that light is an electric phenomenon	1872	Clerk Maxwell	England
Automatic air brake	1872	George Westinghouse	Utd. States
Automatic car coupler	1873	E. H. Janney	Utd. States
The photographic platinotype process. Prints by this process are permanent	1873	Willis	England
Quadruplex telegraph	1873	T. A. Edison	Utd. States
Twine binder for harvesters	1873	M. L. Gorham	Utd. States
Gelatino bromide photographic emulsion. (Sensitiveness to light greatly increased by the application of heat)	1873	Charles Bennett	England
Self-binding reaper	1873	Locke & Wood	Utd. States
Barbed wire machine	1874	Glidden & Vaughan	Utd. States
Siphon recorder for submarine telegraphs	1874	Sir William Thompson	England
Store cash carrier	1875	D. Brown	Utd. States
Illuminating water gas	1875	T. S. C. Lowe	Utd. States
Roller flour mills	1875	F. Wegmann	Utd. States
Middlings purifier for flour	1875	Geo. T. Smith	Utd. States
Ice making machine	1875	R. P. Pictet	Switzerl'd
Speaking telephone	1876	Graham Bell	Utd. States
Electric candle	1876	Paul Jablochkoff	Russia
The first satisfactory web perfecting printing press	1876	Andrew Campbell	Utd. States
Continuous machine for making tobacco cigarettes	1876	Russell	Utd. States
Steam feed saw mills	1876	D. C. Prescott	Utd. States
The first Portland cement plant in U. S.	1876		Coplay, Pa.
Phonograph	1877	T. A. Edison	Utd. States
Gas engine	1877	N. A. Otto	Utd. States
Carbon microphone	1877	T. A. Edison	Utd. States
Telephone transmitter of variable resistance	1877	Emil Berliner	Utd. States
Carbon filament for electric lamp (Beginning of the incandescent vacuum electric light.)	1878	T. A. Edison	Utd. States
Half-tone engraving process	1878	Divided	
Rotary disc cultivator	1878	Mallon	Utd. States
Decided advance in the "Expression" of self-playing pianofortes	1878	Gally	Utd. States
Automatic grain binder	1879	J. F. Appleby	Utd. States
Kathode rays discovered	1879	Sir Wm. Crookes	England
Steam plow	1879	W. Foy	Utd. States
Magazine rifle	1879	Lee	Utd. States
"Blake" telephone transmitter	1880	Blake	Utd. States
Hammerless gun	1880	Greener	Utd. States
Storage battery or accumulator	1880	Camille A. Faure	France
Typhoid bacillus isolated	1880	Eberth & Koch	Germany
Pneumonia bacillus isolated	1880	Sternberg	Utd. States
Button hole machine	1881	Reece	Utd. States
Improvement in "Expression" of self-playing pianofortes	1882	Schmaele	Utd. States
Hand photographic camera for plates	1881	Wm. Schmid	Utd. States
Tuberculosis bacillus isolated	1882	Robert Koch	Germany

INVENTIONS	Date	Inventor	Nativity
Hydrophobia bacillus isolated	1882	Louis Pasteur	France
Cholera bacillus isolated	1884	Robert Koch	Germany
Diphtheria bacillus isolated	1884	Loeffler	Germany
Lockjaw bacillus isolated	1884	Nicolaier	France
Antipyrene	1884	Kuno	Utd. States
Linotype machine	1884	Ottmar Mergenthaler	Utd. States
The rear-driven chain safety bicycle	1884	George W. Marble	Utd. States
Chrome tanning of leather	1884	Schultz	Utd. States
Process of reducing aluminum	1885	Cowles	England
Gas burner	1885	Carl Welsbach	Austria
Hydraulic dredge	1885	Bowers	Utd. States
First electric railway in United States, Hampden and Baltimore, Md	1885		
Contact device for overhead electric trolley	1885	C. J. Van Depoele	Utd. States
Graphophone	1886	Bell & Tainter	Utd. States
Electric welding	1886	Elihu Thompson	Utd. States
Combined harvester and thresher	1886	Matteson	Utd. States
Band wood saw	1887	D. C. Prescott	Utd. States
Cyanide process of obtaining gold and silver	1887	McArthur & Forrest	Utd. States
System of polyphase electric currents	1887	Nicola Tesla	Utd. States
Incandescent gas light. The formation of a cone-shaped interwoven mantle of thread coated with a refactory rare earth and rendering the same incandescent by the heat rays of a Bunsen gas burner regardless of how the gas is produced.	1887	Carl A. von Welsbach	Austria
Process of annealing armor plate	1888	Harvey	Utd. States
"Kodak" snap-shot camera. Constructed to use a continuous sensitized ribbon film.	1888	Eastman & Walker	Utd. States
Process of making artificial silk	1888	H. DeChardonet	France
Hertzian waves or electric wave radiation	1888	Heinrich Hertz	Germany
First practical "horseless carriage"	1889	Serpollet	France
Electrolytic refining	1889	Weston et al.	Utd. States
First rotary cement kilns in U. S.	1889		Coplay, Pa.
Nickel steel	1889	Schneider	Utd. States
Process of making aluminum	1889	Chas. M. Hall	Utd. States
Electric plow	1890	W. Stephens	Utd. States
Improved linotype machine	1890	Ottmar Mergenthaler	Utd. States
Bicycles equipped with pneumatic tires	1890		
Krag-Jorgensen magazine rifle	1890	Krag-Jorgensen	Utd. States
"Coherer" for receiving electric waves	1891	Edouard Branly	England
Rotary steam turbine	1891	C. A. Parsons	England
Cement lined paper pulp digester	1891	G. F. Russell	Utd. States
Round bale cotton press	1891	Brown	Utd. States
Microphone	1891	Emile Berliner	Utd. States
Power loom	1891	Northrup	Utd. States
Commercial application of Formic-aldehyde	1892	J. J. A. Trillat	France
Wireglass	1892	Frank Shuman	Utd. States
Gasoline motor	1892	Otto Daimler	France
Shoe-last lathe for different lengths	1893	Kimball	Utd. States
Kinetoscope	1893	T. A. Edison	Utd. States
Process for making carborundum	1893	E. G. Acheson	Utd. States
Calcium carbide produced in electric furnace	1893	Thos. L. Willson	Utd. States
Argon, a chemical element	1894	Lord Rayleigh and Sir Wm. Ramsay	England
Process for liquefying air	1895	Carl Linde	Germany
Electric locomotive, B. & O. Belt Tunnel	1895		Utd. States
X-Rays	1895	Prof. W. C. Roentgen	Germany
Acetylene gas from calcium carbide	1895	Thos. L. Willson	Utd. States
Motorcycle	1895	Wolfmuller and Geisenhof	Germany
Steam disc plows	1896	Hardy	Utd. States
System of wireless telegraphy	1896	G. Marconi	Italy
Foundation laid of science of radio-activity, i.e., emanation of penetrating rays from luminescent bodies	1896	Henri Becquerel	France
Machine for blowing glass bottles	1896		Utd. States
Use of ultra-violet rays in treating diseases	1896	Niels R. Finsen	Denmark
Nernst electric light	1897	Walter Nernst	Germany
Method of rendering a clay compound capable of conducting electricity and thence becoming brilliantly incandescent without a vacuum.			
Internal combustion engine	1897	Diesel	Germany
Thermit process	1897	Goldschmidt	Germany
Ore-unloader	1898	G. H. Hulett	Utd. States
Radium discovered	1898	Madame S. Curie	France
Mercury vapor electric light	1900	Peter Cooper Hewitt	Utd. States
Auto plate	1900	H. A. W. Wood	Utd. States
Ocean-going submarine	1900	Credit divided	
Electrolytic steel	1900	Kiellin-Heroult	
High speed steels	1900	Taylor & White	Utd. States
Ocean wireless telegraphy	1901	G. Marconi	Italy
Air-ship	1901	M. Santos-Dumont	France
Automobile mower	1901	Deering Harvester Co.	Utd. States
The first passenger steam turbine ship, *Edward VII*	1901	Denny & Brothers	England
Nitrogen from air	1903	Birkeland	Norway
Nickel storage battery	1903	Edison	Utd. States
Aeroplane	1905	Wright Brothers	Utd. States
Gyroscopic compass	1906	Anschutz-Kampfe	Germany
Caterpillar tractor, predecessor of the War "tank"	1906	D. Roberts	Utd. States
Removable auto-tire	1907	Disputed	
Cracking oils for gasoline	1908	Divided credit	
Kinemacolor moving pictures	1911	Urban-Smith	England
Metal-spraying plating machine	1913	M. U. Schoop	Swiss
Air-cooled gun	1914	I. N. Lewis	Utd. States
Phonopticon	1915	F. C. Brown	Utd. States
70-mile gun	1918		Germany

It is interesting to note that between the years 1872 and 1915 there were on what may be termed the honor roll of inventors over 40 inventors each of whom had received over 100 patents. A few of the most important include Thomas A. Edison, 977; Francis H. Richards, 847; Elihu Thompson, 617; Charles E. Scribner, 437; George Westinghouse, 340; Edward Weston, 299.

In the preparation of the foregoing statistics, credit is given to L. H. Campbell, of the United States Patent Office, for valuable assistance.

FREDERICK C. BEACH, Ph.B.,
Late Editor of 'The Scientific American.'

INVENTORY, a detailed written schedule or list of chattels, goods, merchandise, debts, credits, lands, tenements, etc., made either for commercial purposes, or for legal proceedings, such as bankruptcy, etc. It began in Roman law, under which the heir, on filing an inventory of the decedent's estate, was not liable for the latter's indebtedness beyond the sum which descended to him. In nearly all modern legal systems executors and administrators are obliged to make an inventory of the property in their charge in order to secure it to the persons entitled to it. Guardians and curators in some jurisdictions are obliged to file inventories of the estates held in trust by them for their wards.

INVERARAY, Scotland, royal and municipal burgh, capital of Argyllshire, situated on Loch Fyne, at the mouth of the Aray, 40 miles northwest of Glasgow. The town contains an obelisk in memory of the Campbells who were hanged here without trial in 1685, an ancient market cross and a church. Herring fishing is the principal industry. It became a burgh in 1472 and was made a royal burgh in 1648. Inveraray Castle nearby is the seat of the dukes of Argyll. Pop. 533.

INVERCARGILL, New Zealand, city, situated on New River, South Island, some 17 miles inland and 140 southwest of Dunedin. Owing to its proximity to Foveaux Strait, the town enjoys considerable maritime prestige. It has three outlying towns on the Bluff, called North Invercargill, South Invercargill and East Invercargill. It is situated in a rich agricultural district, has manufactures of woolens and flour and saw mills. Pop. including suburbs 15,858.

INVERNESS, Canada, town of Inverness County, Nova Scotia, on the Inverness Railway and on Big River, 150 miles from Sydney. In the neighborhood are found coal, gypsum, copper and fire clay. Pop. 2,719.

INVERNESS, Scotland, a royal, municipal, police burg and capital of the county of the same name, chief town of the Highlands, situated at the mouth, and mostly on the right bank, of the river Ness, on the Highland Railway, 109 miles west northwest of Aberdeen. Its environs, well cultivated and beautifully wooded, are almost surrounded by mountains and hills of various heights, forming a picturesque and interesting landscape. Inverness is a very ancient town, and was one of the Pictish capitals. It has a quite modern appearance with wide streets, beautiful suburbs and fine villas. The first charters of Inverness as a burgh were granted by King William the Lion. In 1411 the town was burned by Donald, Lord of the Isles, on his way to the battle of Harlow and in 1427 a parliament was held here by James I. In High street stands the famous town cross and the Clach-na-cuddin, an ancient stone. In the same street are the town hall and the exchange. The town contains the Raining's School, a royal academy, Saint Andrew's Cathedral, a public library, infirmary, asylum and observatory. The industrial establishments comprise shipyards, woolen factories, foundries, tanneries, soap works, railway shops, saw mills, thread mills, etc. There is a considerable coasting trade. Pop. 22,216. Consult Grant, 'The Commissariat Record of Inverness' (Edinburgh 1897) and Mackintosh, 'Invernessiana' (Inverness 1875).

INVERNESS-SHIRE, Scotland, the largest county of the kingdom, includes Badenoch, Glenroy, and the valley of the Spey on the east, Lochaber on the south, Glenelg, Glen Garry, Arisaig. Moydart and Frazers County on the west, Glen Urquhart and Glen Morriston toward the centre. It includes also Strathglass on the north; and several of the western islands, viz., Skye, Harris, North and South Uist, and Barra, Eigg, etc. The mainland portion is bounded on the east by Aberdeen Banff, Elgin and Nairn, west by the Atlantic and Ross, north by Ross and Cromarty and south by Perth and Argyll. Its area is 4,211 square miles, of which more than two-thirds consist of barren heath. The wildest and most mountainous portion is toward the west, comprising a tract 70 miles in extent, designated the «Rough Bounds.» The most extensive moss in Great Britain lies on the south of Badenoch, where, in the naturally formed wooded islands, large herds of deer find a refuge. The natural pines occupy a larger space than in any other county of Britain. Some mountains attain considerable height. Ben Nevis is 4,406 feet above sea-level and Cairngorm is over 4,000. The geological formation is various; but primary rocks consisting of gneiss, mica-slate, granite, porphyry, and trap rocks prevail. The most fertile soil of the county rests on the red sandstone in the valley of the Aird, and between the county town and Beauly. There are several lakes, as Loch Ness, Loch Lochy, Loch Laggan, Loch Ericht, etc. The principal rivers are the Spey, Lochy, Beauly, Findhorn, Nairn, Ness, Garry, Morriston and the Foyers. The land belongs to about 80 or 90 proprietors. The battle which decided the fate of the Stuarts was fought 16 April 1746 on Culloden Moor, a few miles from Inverness. The Gaelic language is spoken generally. Inverness is the only town. Pop. 87,270. Consult Lees, J. C., 'History of the County of Inverness' (Edinburg 1897).

INVERSION, a change of order whereby the first becomes last and the last first. (1) In rhetoric, a reversal of the natural order of words for the sake of euphony, emphasis or the like; also the turning of one's own argument against him by an opponent in discussion. (2) In chemistry, a change in molecular structure which is usually induced by fermentation or by heating with a dilute acid, as in the case of starch, sugar, etc. Thus starch and dextrine are changed into glucose, cane-sugar into invert sugar, and maltose into glucose. (3) In geology, the overturning or folding over of strata by igneous agency, so that the order of their succession seems reversed. (4) In mathematics, the operation of changing the order of the terms, so that the antecedent shall take the place of the consequent and the reverse, in both couplets. Thus, from the proportion $a : b :: c : d$, we have, by inversion, $b : a :: d : c$. (5) In music, the transposition of certain phrases having a common root. (*a*) The change of a chord by making one of the inner notes act as a bass note, by which means as many inversions can be made as there are actual notes in the chord, not counting the root, the harmony in such inversions remaining the same, though the order of component parts is changed; (*b*) alteration of intervals by making that which was the upper note the lower, and the reverse, the inversion of an interval within the octave being readily found in the difference between the figure 9 and the interval known; (*c*) the alteration of a subject produced by inverting the intervals of which it consists.

INVERTASE, or **INVERTIN,** an enzyme occurring in many fungi, notably in certain yeasts (for example, the saccharomyces), and also in the seed-plants. It transforms cane-sugar into a mixture of dextrose and levulose; this mixture being called «invert-sugar» because it turns the plane of polarized light to the left, while the cane-sugar from which it is obtained turns it to the right. According to some writers, a yeast cannot invert cane-sugar except by secreting invertase; but *Monilia candida* effects the inversion, and yet produces no invertase. In this case the action is probably due to some other enzyme, hitherto unidentified. Invertase probably plays a very important part in vegetable chemistry. Like other enzymes, it can apparently perform an unlimited amount of chemical work, without sensible diminution of its own substance. (See FERMENTATION). Invertase is most active at a temperature of from 120° to 140° F., and in a slightly acid medium. It has been isolated in the form of a powder.

INVERTEBRATES, a collective term for the lower divisions or phyla of the animal series, which agree in not having a vertebral column or back-bone, used in contradistinction to the highest group of the animal kingdom, to which the name *Vertebrata* or vertebrate animals is given. In the system of Cuvier the *Invertebrata* were divided into the *Radiata, Articulata* and *Mollusca.* Further study revealed that these names did not distinguish natural groups; and the term *Invertebrata* has no longer any definite significance in classification.

INVESTITURE, the act of investment implying the right to give possession of an office, honor, benefice or manor. In the mediæval or feudal law, it was the open delivery of a feudal or a right to lands and hereditaments, by a lord to his vassal, thus, by external proof, affording evidence of proprietorship. To use the words of Blackstone, «Investitures, in their original ruse, were probably intended to demonstrate, in conquered countries, the actual possession of the lord, and that he did not grant a bare litigious right, but a peaceable and firm possession. At a time when writing was seldom practised, a mere oral gift, at a distance from the spot that was given, was not likely to be long or accurately retained in the memory of by-standers, who were very little interested in the grant.» For this reason investiture was performed by the presentation of some symbol to the person invested, as a branch of a tree, etc. In the primitive church, after the election of a bishop, and his consecration, the early Christian emperors claimed a right of confirmation. Charlemagne is said to have introduced this practice, and to have invested the newly consecrated bishop by placing a ring and crozier in his hands. Gratian, indeed (Distinct. 63 cap. Adrianus), directly affirms that Pope Adrian positively conceded to the emperor the power of electing, even to the papacy, in 774; but neither Eginhard nor any other contemporary writer mentions this fact.

The custom, however, existed, nor does it appear to have been objected to or opposed during the lapse of two centuries from his reign. The disorderly state of Italy, which succeeded the death of Charlemagne, frequently interrupted the exercise of this right by the Carlovingians; but even so late as 1047, when the empire had passed to another line, Henry III received an explicit admission of his prerogative, and repeatedly used it. The investiture in the lesser sees followed as a matter of course. Alexander II issued a decree against lay investiture in general, which was revived by Gregory VII (Hildebrand), who, having succeeded in annulling the prerogative of the emperors to nominate or confirm popes, sought to disjoin entirely the ecclesiastical from the civil rule. It was not, however, until the papacy of Calixtus II, in 1122, that the question was terminated, as it appears, materially to the advantage of the holy see. In France, even under the papacy of Hildebrand, the right of investiture does not appear to have been made a subject of open quarrel. In spite of the protests of the holy see, the kings exercised the power, but at length relinquished the presentation of the ring and crozier, and contented themselves with conferring investiture by a written instrument, or orally, upon which they were left in peaceable possession of the power. But in England Paschal II was engaged in a contest little less fierce than that which he maintained with the emperor. Anselm, the primate, refused to do homage to Henry I for his see. The king seems to have asserted an unqualified right of investiture, which the Pope, who was appealed to, as unqualifiedly denied. After a protracted struggle, and continued threats of excommunication, the controversy ended in England, as it did afterward in Germany, by compromise. Paschal offered to concede the objections against homage provided Henry would forego the ceremony of investiture. To this he agreed (1107).

INVESTMENT BANKERS ASSOCIATION. See BANKS AND BANKING—BANKERS' ASSOCIATIONS IN THE UNITED STATES.

INVESTMENT BANKS AND BANKING. See BANKS AND BANKING—INVESTMENT BANKING.

INVINCIBLE ARMADA. See ARMADA.

INVINCIBLES, an Irish secret society of 1882, an off-shoot of the Fenians (q.v.). One of the objects of the Invincibles was to «remove» or assassinate government officers or others who might incur the displeasures of the association or its leaders. On 6 May 1882 the society succeeded in «removing» Lord Frederick Cavendish, who had just arrived from England as Secretary for Ireland, and Thomas A. Burke, the under-secretary, in the Phœnix Park at Dublin. The plot was directed against the lat-

ter gentleman, and the former, interfering to protect his friend, shared his fate. On 20 Feb. 1883 20 persons charged with complicity in the Phœnix Park murders were put on trial; on 14 July, Joseph Brady, who had been convicted of actual perpetration of the murder of Mr. Burke, was executed, as were others subsequently. The leading witness, who revealed all the secrets of his fellow conspirators, was James Carey of Dublin. He was shot dead near Natal, on 29 July, by an Irishman, O'Donnell, who was subsequently tried, and executed for his crime.

INVIOLABILITY. See INTERNATIONAL LAW.

INVOICE, a list or bill of goods; a detailed statement of merchandise in stock, or to be shipped. Very frequently an invoice accompanies a shipment of goods along with the bill of lading from the consignor to the consignee. An invoice is a memorandum and is not a document of title nor a contract of sale, and has no value in law other than memoranda. Invoices of foreign goods must be verified at tariff headquarters of some countries.

INVOLUCRE, *in botany,* a group of bracts surrounding flowers in their unexpanded state, and occupying a place on the floral axis beneath them after their expansion. The bracts which form an involucre are generally grouped in a whorl. The cup of the acorn, hazel-nut, etc., may be regarded as an involucre.

INVOLUTION, *in mathematics,* the raising a quantity to any power. Involution is the converse of evolution, in which the root of a quantity is extracted. See ALGEBRA; ARITHMETIC; GEOMETRY; CALCULUS, INFINITESIMAL.

IO, ī'ō, in Greek mythology, a daughter of Inachus; according to others of Iasus or Peiren. Zeus (Jupiter) fell in love with her. Hera (Juno) perceived the infidelity of her husband and resolved to be revenged on both. Zeus, to protect Io from the jealousy of Hera, changed her into a beautiful white heifer. Hera was not deceived and set a gad-fly to torment her, and persecuted her without a moment's rest through the world. The wanderings of Io in this condition were a favorite subject with the poets of ancient Greece. Also, in astronomy (1) the first satellite of Jupiter, discovered by Galileo in 1610. (2) The name of the 85th asteroid, discovered by Peters at Clinton, N. Y., 19 Sept. 1865.

IODINE, ī'ō-dĭn or -dīn, a non-metallic element, analogous in its general properties to chlorine and bromine. It was discovered by Courtois in 1811, in the mother-liquor of kelp that had been used for the production of sodium carbonate; occurring there in combination with sodium and magnesium. It is still obtained from the ashes of certain seaweeds, but the principal supply is now obtained from "caliche," a crude nitrate of sodium that occurs in immense quantities in northern Chile. In the preparation of the commercially pure nitrate of soda from caliche, the mother liquors, after the removal of the nitrate by crystallization, are found to contain large quantities of iodine, chiefly in the form of iodate of sodium, $NaIO_3$; and it is from this substance that the iodine of commerce is now chiefly prepared. The richest caliche contains about 3.5 pounds of iodine per ton.

In its ordinary form, iodine is a solid substance, melting at 237° F., and boiling at about 380° F. In a vacuum, iodine sublimes without melting. Solid iodine is soft and dark gray in color, with a metallic lustre. The vapor is violet in color, from which circumstance the element takes its name (Greek, "like a violet"). Chemically, iodine has the symbol I, and an atomic weight of 126.92 for O = 16. Solid iodine has a specific gravity of about 4.95 at ordinary temperature and a specific heat of about 0.05412. Its volume increases, on account of thermal expansion, by about 0.00013 of its own value for a rise of temperature of 1° F. At temperatures not far above its boiling point, the vapor of iodine has a specific heat (at constant pressure) of 0.03369; and in the same region of temperature the ratio of its specific heat at constant pressure to the specific heat at constant volume is about 1.294. Iodine shows an important change in its vapor density at high temperatures. Thus, below about 1,200° F. the vapor has a density about 126 times as great as that of hydrogen under the same conditions of temperature and pressure; but as the temperature rises the density of the vapor, relatively to hydrogen, falls off, until it is only about 68 at 2,700° F. It is believed that this change in density indicates that the molecules of iodine vapor split in two as the temperature rises; a molecule, just above the boiling point, containing two atoms, while at the higher temperature the molecules are monatomic. Iodine is freely soluble in alcohol, ether, carbon disulphide, chloroform and glycerin. It is only slightly soluble in pure water, but dissolves readily in aqueous solutions of the iodides. It is also soluble in benzine, acetic acid and numerous other organic fluids. Iodine is a non-conductor of electricity.

With hydrogen, iodine forms the important compound HI, known as hydriodic acid. (See HYDRIODIC ACID). With the metals it forms binary compounds called "iodides," which may also be regarded as salts of hydriodic acid. Of these the most important is potassium iodide, KI, which is largely used in medicine. It is prepared by dissolving iodine in a solution of caustic potash, evaporating to dryness and igniting. This salt is very soluble and crystallizes in cubes. The iodides of ammonium, sodium, strontium and zinc are also used to a more limited extent. Iodoform, a yellow crystalline powder with a peculiar characteristic odor when warmed, is also much used as a dressing in surgery. It has the formula CHI_3, and is analogous in its chemical structure and deportment to chloroform. Iodoform may be prepared by dissolving iodine in an alcoholic solution of caustic potash, the iodoform that is produced separating out as a precipitate. It is also prepared in Germany, to a certain extent, by the electrolysis of a similar solution. (Consult Löb, 'Electrolysis and Electrosynthesis of Organic Compounds'). Iodine and its compounds are used to some extent in photography, and to a larger extent in synthetic chemistry, for the preparation of the coal-tar colors (q.v.), and other organic substances.

Iodine forms two important oxy-acids, known respectively as iodic acid, HIO_3, and periodic acid, HIO_4+2H_2O. These are analogous, in their chemical deportment, to chloric and perchloric acids. It also forms the interesting chlorides IO and ICl_3.

Free iodine combines with starch to form a remarkable deep blue compound, whose production is a well-known test for the presence, in a given substance, of either starch or free iodine. To detect the presence of iodine in a solution, a few drops of thin, clear starch paste are added to the solution to be tested (which should be cold), and hydrochloric acid is added until the reaction is acid. A couple of drops of a concentrated solution of potassium nitrite are then added, when the dark blue color of iodide of starch will instantly be produced, if iodine is present. This test may readily be modified so as to serve for the detection of starch. The reaction is not given by dextrin, nor by other isomers of starch.

Iodine is used medically in a compound solution with KI, in alcoholic solution or as a component in an ointment. These preparations are valuable counterirritants and antiseptics. A preparation of iodine and wood tar is used in ringworm. See HYDRIODIC ACID; IODINE IN MEDICINE.

IODINE AND IODIDES IN MEDICINE. Iodine and its iodides—especially those of sodium and potassium—have been used in medicine since the Chinese are supposed to have introduced them, 2000 B.C. or earlier. The exact method of action of the iodides is not clear, but it would seem that iodine, being a normal constituent of the human body, is a very essential element in normal metabolism. It is found in comparatively large quantities in the thyroid gland, which is known to exercise a very important action in the general body-metabolism, and it is probably by means of the stimulation of the general metabolism of the body that the iodides manifest their beneficial action. The iodides are freely absorbed from watery solutions by mucous membranes throughout the body, particularly in the stomach and intestine. They are taken up into the blood, pass through the tissues, stimulating the lymph-flow, and are excreted in the urine in the form of salts. The iodides are likely to irritate the digestive system. Iodine itself possesses a local irritant action. It is soon converted into the iodides when taken internally, and causes similar internal changes.

When the iodides are taken in large doses, or even in small doses for a long time, a form of chronic poisoning known as iodism results. In this the chief symptoms, found in the air-passages, consist of a catarrh, especially of the nose, with profuse watery secretion, sneezing and sometimes bronchitis. There is usually swelling and irritation of the throat and tonsils, and salivation. Nausea and gastric discomforts are common, and skin-eruptions are frequent. There is usually loss of weight, and if the iodide has been taken for a very long period a condition of cachexia, characterized by a great loss of flesh, weakness, depression and restlessness, may result. The chief use of the iodides in medicine is in the treatment of tertiary syphilis, on which it has a specific effect. It is also useful in actinomycosis, metal poisoning, high arterial tension, arteriosclerosis, aortic aneurism, colloid goitre and rheumatic affections. It is also very useful in the various joint-pains of a chronic character, usually known as chronic rheumatism. Iodine is valuable in the treatment of those diseases known to result from thyroid insufficiency, notably in myxœdema (q.v.), and in cretinism, its allied form in children. For stimulation of the respiratory and nasal passages, as in chronic bronchitis, asthma and dry nasal catarrh, the iodides are of great value.

IODOFORM. Tri-iodomethane, CHI_3, was discovered by Serullas in 1822. It is formed by the interaction of ethyl alcohol and iodine in the presence of caustic alkalis. Acetone, acetaldehyde and many other compounds may also yield varying quantities of iodoform when treated with iodine and caustic alkalis or carbonates. Iodoform has also been obtained from derivatives of acetylene; and of late years it has been formed from ammonium iodide in the presence of potassium hypoiodite, potassium carbonate and ammonia.

On a commercial scale iodoform is prepared by the addition of iodine to an aqueous solution of sodium carbonate in the presence of ethyl alcohol. The temperature of the reaction mixture is maintained at 70°–80° C. The main portion of the iodine is converted into iodoform, which being insoluble forms a yellow precipitate. The remainder of the iodine dissolves in the reaction mixture as sodium iodide. From the latter the iodine is recovered by the use of chlorine, and converted into iodoform with an additional quantity of sodium carbonate and alcohol. A repetition of this process will increase the yield of iodoform. In this method acetone may be substituted for ethyl alcohol, and potassium carbonate for sodium carbonate.

A second process, extensively employed at the present time, consists in the electrolysis of a water solution of potassium iodide, alcohol or acetone, and an alkaline hydroxide or carbonate, at a temperature of 65° C.

Iodoform crystallizes in lemon-yellow plates. It has a persistent unpleasant odor, melts at 119° C. and dissolves in absolute alcohol, ether, carbon bisulphide and other solvents. With alcoholic potash it yields potassium formate and potassium iodide. In the presence of arsenious acid and sodium hydroxide it is converted into methylene iodide, and with phosphorus pentachloride it yields chloroform. With dry silver nitrate iodoform forms an explosive mixture.

Iodoform was first employed in the treatment of wounds in 1880. When brought in contact with wounds or sores it acts as a good antiseptic and promotes healing. The action is probably due to the liberation of iodine and other products at the temperature of the body. It is extensively used in the treatment of scrofula, goitre, cancer and in syphilitic and tuberculous ulcerations. When iodoform is taken in large doses into the system, it may produce symptoms of poisoning, nausea and vomiting, headache, sleepiness, hallucinations and even death.

The objectionable odor of iodoform has been masked by combining it with a variety of substances such as volatile oil of camphor, balsam of Peru and paraformaldehyde. A number of good iodoform substitutes have been prepared. Some of these are related to iodoform both in composition and in their mode of

decomposition. Iodoformin, for example, is a compound of iodoform and hexamethylene tetramine; it liberates iodoform when it is used as a dressing on wounds. Iodol (tetra-iodo-pyrrol), and aristol (dithymol di-iodide) are also more or less related to iodoform. Among other substitutes for iodoform may be mentioned europhen, vioform, xeroform, noviform, loretin and airol.

V. S. Babasinian,
Professor of Chemistry, Lehigh University.

IODYRITE. A native iodide of silver AgI, with 46 per cent of silver. Occurs in Lincoln and Mineral counties, Utah, and at Lake Valley, New Mexico.

IOLA, ī-ō'la, Kan., city and county-seat of Allen County, on the left bank of the Neosho River, about 40 miles west of the Missouri line and about 100 miles south of Kansas City. The town is reached by the Atchison, Topeka and Santa Fé, the Missouri, Kansas and Texas and the Missouri Pacific railroads. It was laid out by the Iola Town Company in 1859. In 1865 it became the county-seat of the county, and grew steadily, although slowly. In 1896 natural gas was discovered on the town site, and the town began to grow rapidly, with the location in and near Iola of nine large zinc smelters, a number of brick factories, two Portland cement plants and other manufacturing enterprises attracted to the place by the cheap fuel which the large field of natural gas supplied. The leading church denominations are the Presbyterian, Methodist Episcopal, Christian, Baptist, Episcopal, Reformed and Catholic. The city is well supplied with schools, its high school being one of the best in the State. There are two daily papers, the *Journal* and the *Register*. The city is surrounded by a well-settled and prosperous agricultural community, but the chief business is derived from the manufacturing industries. The population is almost wholly American, the exceptions being a few Poles and Swedes employed in the manufacturing plants. An electric road connects Iola with a number of suburban towns, increasing the population to 14,000. Pop. 8,513.

IOLITE, a mineral, the formula of which is $Mg_2Al_4Si_5O_{18}$. It crystallizes in the orthorhombic system, in the form of short columns of a hexagonal tendency. It is blue but shows different tints under different lights, and consequently known as dichroite. Its hardness is 7–7.5, its specific gravity 2.6. Some of the aluminium may be replaced by iron. Since water is found on the analysis of fresh specimens, the formula is sometimes written $H_2Mg_4Al_8Si_{10}O_{37}$. It is an essential component of many gneisses, and is found in Bavaria, Finland, Connecticut, Ceylon and Spain. Deep blue specimens are known as lynx sapphire; light blue ones may be known as saphir d'eau or water sapphire.

ION OF CHIOS, Greek author: b. about 500; d. about 422 B.C. In 478 he came to Athens where he made the acquaintance of the leading men of the time including Cimon, Pericles, Æschylus and probably Sophocles. He is the author of 'Επιδημίαι,' a volume of which we possess but a few fragments. It was used extensively by later Greek historians. He also wrote tragedies, lyrics and other verse. Consult Müller, 'Fragmenta Historicorum Græcorum' (1853); Allègre, 'De Ione Chio' (Lyons 1890); Nauck, 'Tragicorum Græcorum Fragmenta' (Leipzig 1889) and Christ-Schmidt, 'Geschichte der griechischen Litteratur' (Vol. I, 5th ed., Munich 1908).

IONA, or **ICOLMKILL,** Scotland, an island on the west coast, one of the Inner Hebrides, in the county of Argyle. Iona is about three miles long by one and one-half miles broad; area, 2,000 acres, of which 600 acres are under cultivation, the remainder being hill pasture, morass and rock. The island is celebrated for its history and its ancient ruins, and epecially from its connection with Saint Columbia, who took up his residence here after the middle of the 6th century (565). The existing ruins are all, however, of a much more recent date. Forty-eight kings of Scotland, four kings of Ireland and eight kings of Norway are said to have been buried on Iona Island, among them being King Duncan, made famous by Shakespeare. About 1900 the Duke of Argyle conveyed the entire island to the Church of Scotland under certain conditions of preservation and restoration.

IONE, ī'on, Cal., village in Amador County, on the Southern Pacific, 40 miles southeast of Sacramento. The surrounding region is well adapted to agriculture and has extensive coal deposits. The village is the seat of the Preston School of Industry. Its industrial establishments are limited to flouring mills and a creamery. Pop. 1,550.

IONIA, ī-ō'nia, Asia Minor, that part of the seaboard which was inhabited by Ionian Greeks, a beautiful and fertile country opposite the islands of Samos and Chios, which also belonged to it. According to tradition, the Greek colonists came over from Attica about 1050 B.C., and founded 12 towns, which, though mutually independent, formed a confederacy for common purposes. These included Phocæa, Ephesus, Miletus, etc., and latterly Smyrna. Commerce, navigation and agriculture early rendered them wealthy and flourishing, but the country was made tributary by Crœsus, king of Lydia, and later by Cyrus, king of Persia (557 B.C.). With an interval of independence they remained under Persia until this empire was overthrown by Alexander the Great, 334–331 B.C., when they became a part of the Macedonian Empire. Ionia, at a later period, became part of the Roman province of Asia. It was afterward totally devastated by the Saracens, so that few vestiges of its ancient civilization remain.

IONIA, Mich., city and county-seat of Ionia County, on the Grand River, and the Detroit, G. H. and M., the Pere M. and the Grand Trunk railroads, 34 miles east of Grand Rapids. It contains the State house of correction, the State asylum for the dangerous and criminal insane, large railroad repair shops, and manufactories of pottery, furniture, machinery, edged tools and clothing. The industrial interests are greatly promoted by excellent power furnished by the river. The city has a public high school, library, several daily and weekly periodicals and an assessed property valuation of about $4,500,000. Under the revised charter of 1897, the government is administered by a mayor and city council elected annually. Ionia

was settled in 1833 and incorporated in 1873. Pop. (1920) 6,935.

IONIAN ISLANDS, a number of islands belonging to the kingdom of Greece, in the Ionian Sea, off the coast of Albania and the western and southern shores of Greece, the most southern, Cerigo, and its dependent islets being off the southeastern extremity of the Morea. The principal islands, seven in number, are, reckoning from north to south, Kerkyra (Corfu), Paxos, Levkas (Santa Maura), Ithaki (Ithaca), Kephallenia (Cephalonia), Zakynthos (Zante) and Kythira (Cerigo). To each of these larger islands a number of smaller, scattered along their respective coasts, are attached and included in their several local jurisdictions. Area of the whole, 1,117 square miles. Pop. about 226,590. All these islands belong to the great calcareous formation of Greece. They are extremely mountainous, and do not contain enough arable land to produce the corn required by the population; and were it not for the vine, olive and currant, all of which they produce, they could support but a small number of inhabitants. The climate is even more temperate than that of the neighboring mainland. Snow often falls in the winter and lies on the mountains, but rarely on the plains. The staple exports are oil, currants, valonia, wine, soap and salt. The few manufactures are chiefly textile and ornamental. The religion is that of the Eastern Greek Church, to which four-fifths of the population belong. Each island has its own bishop, and at the head of the whole is an exarch or primate. In 1867 a series of disastrous earthquakes took place. The Ionian Islands, so called from lying in that part of the Mediterranean anciently known as the Mare Ionicum or Ionian Sea, often figure in the ancient history of Greece, but only singly, not collectively. In 1809 all the islands were captured by the British troops except Corfu, which did not come into their hands till it was assigned to them by the Peace of Paris in 1814, possession being finally fixed and regulated by another treaty concluded at Paris in 1815. The seven islands were then formed into a republic, under the protectorate of Great Britain. In 1857 a desire was expressed by their representatives for reunion with Greece, and the islands, with the consent of the other European powers, were transferred to the kingdom of Greece in 1864. See Greece.

IONIAN PHILOSOPHY, early Greek hylozoism and henism of the thinkers of the Ionian School (q.v.). The term hylozoism is apt to be misleading, the term henism to be misunderstood, and we may therefore give them passing notice. First, hylozoism is *not* synonymous with materialism. Materialism is that world-conception which attempts to explain all phenomena from matter and motion, which in a radical form materializes even things immaterial. Not so with hylozoism. To some, of course, it suggests theories which deny the separate reality of life and spirit. And, indeed, in the days of the first Ionian thinker, Thales, and even far later, it cannot be denied that the distinction between matter and spirit had not been keenly felt, still less formulated in such a way that it could be either definitely affirmed or denied. But the uncreated, indestructible reality of which Ionian thought concerns itself was a body, or even matter if we choose to call it matter: but it was *not* matter in the sense in which matter is opposed to spirit. Hylozoism thus is characteristic of any system which explains all life, whether physical or mental, as ultimately derivable and derived from animated matter. Ionian hylozoism consisted chiefly in an inquiry after the first principle or element, regarded as animated, out of which the sense-perceptible world is constructed. Thus Thales, Anaximander, Anaximenes, Heraclitus, Anaxagoras and other Ionian thinkers, on account of their having followed one general tendency, possess, intellectually considered, another common characteristic. In thought they are henistic. By henism is to be understood those philosophic efforts to subsume everything under one general notion, be it motion, or matter, or spirit, or matter in motion, or evolution, or an unknown substratum, like the Kantian "thing-in-itself" and the Spencerian "unknowable." Henism is, briefly, one-notion, single-idea philosophy. All Ionian philosophers asked: From what did the world come? The growing body of thought which may be traced through successive representatives of the Ionian school is always that which concerns a primary substance. The astronomical and other theories are, in the main, peculiar only to the individual thinkers of the school. Greek philosophy thus began as it ended, with the search for what was abiding in the flux of things.

Philosophy arose in Greece as elsewhere in the attempt to discover the *laws* of outward phenomena, and the origin and successive stages of the world's development. The earlier thinkers stand in closer relation to the previous religious or mythical views; they seek to substitute an intelligible hypothesis, based on real things, for the myths of the poets. Even the myths, however, which described the generation of the gods and the origination of worlds, implied, at least, a view of a single connected world-process, and of an inclusion of all in the universe within that process. Sky, earth, sea, days, seasons, in short, all detached phenomena were given unity and relation even in the Greek poets, in such beings as *Gaia* (earth) and *Ouranos* (heaven) and similar deities. Thus, most in touch as were the earlier Ionian thinkers with the Olympian religion, with its deities of the sky and the ocean, their task was to substitute for such personifications actual concrete substances, a work they sought to complete through closer contact with nature. All sought to explain the material universe as given in sensory experience. The chief aim was to secure an answer to the inquiry: What is the one original element, if indeed it is only one, or what are the original elements, if more than one, of which the universe consists? The philosophers found ready to hand in the mythic cycles the conception that the world was *one*. From what did it come? Their answers were usually given in terms of matter, movement and force. Concerned mainly with the ontological or metaphysical problem, the thought of the Ionian thinkers was in its chief characters cosmological. The other problems of the philosopher, epistemological, logical, ethical and æsthetical, receive, when they receive any attention, only passing notice from the Ionians. The characteristic work which distinguishes the

speculations of this school is the endeavor to refer all sensible things back to one original principle in nature. And as their efforts began with a search for laws, so were those efforts rewarded by the earliest conception of what became the most fruitful idea evolved in the whole body of Ionian thought, namely, the notion of "rational law" or *logos*, and "justice" (*ζικη*), which controls a world process and regulates allotted changes. When the regular course of nature was first realized by members of the Ionian School. no better word for it could be found than "*ζικη*." It is the same metaphor which still lives on in our expression "natural law." Here we see the decree of Zeus, the destroyer of the gods, the social and religious law of justice, becoming the central conception for viewing the physical process, an achievement which could not dispose of all those implications, like for example fatalism, which cling to the modern term law even in the science of to-day. A law of changes gave a union of the "one" and the "many" to the thought of some of these early thinkers. All the members of the school were one in method and in aim. The one great principle which underlies all Ionian thought, though it is first put into words by Parmenides, is that "nothing comes into being out of nothing and nothing passes away into nothing." Their acute penetration into the philosophical problem is testified by the fact that they attempted to recover not only the beginning of all things, but the eternal ground of all things for thought. And it is true that important beginnings of a theory of evolution are to be found in the speculations of the earliest Grecian school of philosophy.

"Nothing is born of nothing" (Parmenides of the Eleatic School). From what then did the existing world come? In the history of the Ionian School (q.v.) two principal ways of viewing nature, a dynamical and a mechanical way, present themselves at its very beginning and proceed side by side to its very close. The dynamical theorist proceeds on the supposition of a living energy which in its development spontaneously undergoes continuous alteration both of form and quality and consequently considers all generation in nature as explicable by successive transmutations of energy. The mechanist, on the other hand, rejects all generation in the proper sense of the word and all alteration of the qualities and forms in nature, and accounts for all appearances by certain changes in the outer relations of space. Here a theorist proceeds, therefore, on the assumption of certain permanent material elements, which change place in obedience to motion, either originally inherent or extrinsically impressed; and thus it is a theoretical explanation of the world which if carried out in all its implications will lead to the conclusion that all apparent generation of natural forms and qualities is educed by the various combinations into which material elements of originally distinct forms mutually enter. The two theories rest on views directly opposed to each other. With the exceptions of Anaxagoras, Anaximander and Archelaus, the Ionian hylozoists all show an inclination to adopt the dynamical explanation of the world. By all, excepting the three philosophers named, *nature* is regarded as naively animated, alive, and its successive changes as so many spontaneous developments of life. And by them it was accepted as a principle that a single elementary substance passes through a series of transformations, by means of expansions, condensations and other modifications considered as processes of life. Thus those who admitted one rather than a plurality of elements were obliged to endow it with a principle of vitality to account for existing variety. They thus adopt dynamism, a rather crude form of henism. Archelaus, Anaximander and Anaxagoras, on the contrary, believed in a plurality of elements, two or more, and considered mechanical interaction of these as sufficient to account for the existing state of things. What is the original element, if only one, or, what are the original elements, if more than one, of which the universe consists. Two periods can likewise be distinguished in the development of the reply to this question owing to its reformulation and the manner in which different thinkers in the school approached it. Prior to the advent of Heraclitus attempts were made to find a material substance of which all things consist. What were the materials out of which all things arose and into which they will again return? What is the substratum of things seen? Thales, Anaximenes, Diogenes and other dynamists as well agree in regarding the universe as the result of a single principle, element or power. All sensible things are modifications of this principle, real only in reference to their ultimate ground, a substance of which all things consist. After the time of Heraclitus the question became: How did the sensible world become what it is? Of what nature is the motive force? Here the germs of a more philosophic doctrine is apparent. Heraclitus, indeed, retains the simplicity of an original element, his "fire," but it is apparent that this fire is only a sensible symbol, used only to present more vividly to the mind the idea of an energy of a vital principle, the ground of all outward appearances. He with his principle of universal flux gave thinking a new turn and proceeded to explain everything in terms of force and motion, or dynamic energy. It would indeed be a mistake to regard philosophers of the Ionian school as materialists. They distinguish between law operating in the external world and the apprehension of phenomena; and vaguely also between subjective and objective. But we meet with thinkers of the mechanistic tendency. Anaxagoras and Anaximander agree in this respect, that they consider the world to be made up of numberless small particles of different kinds and various shapes by the change in whose relative position all phenomena are to be accounted for. This hypothesis is combined by Anaxagoras with the Supreme Reason, author of all that is regular and harmonious in the disposition of the particles or elementary atoms. Out of what did the existing world proceed? Thales, the first Ionian philosopher, answered out of water, which Anaximander denied and replied that the ground of all being is the boundless, the infinite or the all-embracing. Pherecydes of Syra believed that the primal substratum of all things was earth; but both Anaximenes and Diogenes contended

that the existing state of things proceeded out of air. Heraclitus said the original element was fire; Anaxagoras, however, that the world came into being through the motor energy of intelligence; while Archelaus, the teacher of Socrates, believed that primordially the elements were two in number, fire and water, sense-perceptible symbols of heat and cold which can be felt but not seen. And to Hermotimus, whose existence, however, some deny, deeming him mythical, others credit the original formulation of the doctrine of the supreme regulative intelligence, an idea which he is said to have taught his pupil Anaxagoras.

Aristotle believed that the view of Thales had its origin in the observation that all that *grows* appears to have its nourishment in moisture and the observation that *germination* seems to owe its existence to the presence of water. Aristotle adds further that Thales maintained the world to be full of gods and that all motion indicated their presence and the presence of souls. Thales believed that behind infinite multiplicity there was unity. This unity he symbolized with water. Anaximander sought for the primal substance of all things; and postulated an entity intermediate between air and fire on one hand; between earth and water on the other. This entity he called the infinite. To him all differences being finite, these differences have emerged out of the infinite. This infinite has been always and will remain throughout all eternity. Change, growth and decay are explained on the principle of compensation. All things proceeded out of the infinite. All will at some time return to it. According to all appearances, Anaximander's "infinite" is equivalent to the "chaos" of other philosophers and of the myths. "Nous," according to him, is the most pure and subtle of all things. It has all knowledge about all things and also infinite power. Anaximander's theory is thus only one step from pure theism. With him the work of the eternal begins with a kind of providence, not with creation. He did not allow that objects had taken their shape through the accidental or through blind fate. They received their form through the agency of a shaping spirit or Nous, infinite, or boundless, self-potent and unmixed with anything else. The infinite always preserved its unity; its parts alone underwent changes. Thus he tells us that there are an infinite number of worlds, a product of infinity, and that corruption proceeds from separation. Anaximenes made the first principle of things to consist in air, an entity considered as infinite, and possessed of perpetual motion. All things proceeded from this air; all are definite and circumscribed; and divine power resided in air and agitated it. Coldness and moisture, heat and motion rendered this substance visible. Likewise they gave air forms, according to the different degrees of condensation. All elements thus proceed from heat and cold. Diogenes contradicted the pluralism of Heraclitus and claimed that all things were at bottom the same, or interaction he claimed would be impossible. The substrate confirming the opinion of Anaximenes, he declared, was air; and gave it out that the attributes of this substrate were infinity, eternity and intelligence. This intelligence alone, according to Diogenes, would produce unaided the orderly arrangement which is observable in nature; and it is likewise the foundation of human mentality, which originates simply by inhalation. Anaxagoras may be considered the first who clearly and broadly distinguished between mind and matter. By isolating reason from all else, by representing it as motor-energy of the Cosmos, in popularizing the terms which suggested personality and will, Anaxagoras gave an impetus to ideas which were the starting point of Aristotelian philosophy in Greece and in Europe at large. Before Anaxagoras no one can be said to have postulated clearly a creative intelligence. In nature this thinker imagined that there are as many kinds of principles as there are species of compound bodies. He was the first to superadd mind to matter, opening his work with the pleasing language: "All things were confused. Then came mind and disposed them in order." Heraclitus felt that charge is the essential fact of experience. That this is, what it is, in virtue of its perpetually changing relations. Fire, symbol of the primary substance, is that out of which all came, into which again all will return. It is a divine, rational process, the harmony which constitutes the universe. Here follows the doctrine of immortality. The individual, like the phenomena of sense, comes out of the infinite and is again merged in it. While we live our souls are dead within us. When we die our souls are restored to life. For then they approach most nearly to perfection when least differentiated from the elemental fire. This is at once the assertion and the denial of self — resembling a fundamental principle in Buddhism. See GREEK PHILOSOPHY; PHILOSOPHY; PHILOSOPHY, HISTORY OF.

IONIAN SCHOOL, at times called also the Ionian Sect, was the oldest among the ancient schools of Greek philosophy. It originated in Asia Minor under Thales of Miletos, about 600 years before the beginning of the Christian era. Diogenes Laërtius places the birth of Thales during the 35th Olympiad, that is, between 640 B.C. and 636 B.C.; and the philosopher died, according to Apollodorus, in his 78th year, but according to Sosicrates, in his 90th year. The other most famous exponents of Ionian thought after the advent of Thales of Miletos were Anaximander of Miletos, Pherecydes of Syra, Anaximenes of Miletos, Heraclitus of Ephesus, Diogenes of Apollonia and Anaxagoras and Hermotinius of Clazomenæ. It is a most interesting fact in the history of Greek thought that its birth took place not in Greece but in its colonies on the eastern shores of the Ægean Sea. The first name in the list, not alone of Ionian, but indeed of European, thought, is Thales. From Asia Minor the *spirit* of Ionian philosophy passed into Greece, at first under Anaxagoras, then afterward under Archelaus, the master of Socrates. The interval between Thales and Archelaus amounted to a period of not less than 150 years. Thus Athens, taught from Ionia, became in turn the headquarters of philosophy and the parent of the most celebrated Greek schools. The labors of the Ionian School cleared the way for all those schools which at a later period undertook to explain the physical world and served at once as a model and as a starting point for Leucippus, Democritus, Empedocles, Aristotle

and Epicurus. In truth most of the schools which arose in Greece from the time of Thales to the time of the great thinker Socrates—roughly speaking during the period between 600 B.C. and 400 B.C.—and constituted the first philosophic period, were in some sort so many offshoots of the Ionian School. Pythagoras, born at Samos, became the pupil of Pherecydes; Xenophenes, the founder of the Eleatic School, was a native of the Ionian city of Colophon; Abdera, the birthplace of Leucippus and Democritus and the seat of the school which they founded, was a colony from Phocæa; and besides, Democritus was the pupil of Anaxagoras. In the course of its development, the Ionian School was contemporary with other Greek schools, among which the Abderitan and Eleatic schools and the systems of Empedocles and Pythagoras were the most important.

The Ionian Philosophy (q.v.), notwithstanding the celebrity of its first professors, most of whom are named above, soon failed in classical Grecian schools and in Greece never afterward recovered its ancient reputation and authority. This was owing to the suspicion of impiety under which it lay in Athens; to the early growth of new branches from the Socratic stock; and to the rise and spread and vigor of the Eleatic and the Epicurean mode of thought. Ionian philosophy thus disappeared in antiquity for the first time owing to the dual opposition of sullen, unlearned bigotry and the incissive critique it received at the hands of its more profound rivals, like, for example, the Socratic Philosophy.

History has preserved the record of numerous attempts that have been made to form a rational conception of the whole world of phenomena and to recognize in the universe the action of one sole active force by which matter is penetrated, transformed and animated. These attempts are traced in classical antiquity in those treatises on the *principles of things* which emanated from the Ionian School and in which all the phenomena of nature were subjected to hazardous speculations based upon a small number of observations. By degrees, as the influence of great historical events has favored the development of every branch of science supported by observation, that ardor has cooled which formerly led men to seek the essential nature and connection of things in purely rational principles. In recent times the mathematical portion of natural philosophy has been remarkably and admirably enlarged. The method and the instrument (analysis) have been simultaneously perfected. That which has been acquired by means so different by the ingenious application of atomic suppositions, by the more general and intricate study of phenomena and by the improved construction of new apparatus—is now the common property of mankind.

Thales and the earlier members of the school stand in closer relation to the previous mythic and religious cosmologists than the later members. And they seek to substitute intelligible hypothesis, based on real things or events, for the myths of the poets. The first attempt to disenthrall the philosophic intellect from the all-personifying religious faith and to constitute a method of interpreting nature distinct from the untaught inspiration of inferior minds is to be found in Thales in the 6th century before the Christian era. It is to Thales and to a small number of other independent Greek thinkers that philosophy owes the substitution of an impersonal nature for the personified cosmos, conceived as the proper object of study. The Greek word, φυσις, denoting nature and its derivatives *physics* and *physiology*, unknown in the sense which Thales understood it to Homer and Hesiod, as well as the word *kosmos* to denote the mundane system, first appears in these philosophers' speculations. But it must be allowed that the distinction between personal and impersonal was not strongly felt in antiquity and it is a mistake to lay overmuch stress upon it. It seems rather that the real advance made by the scientific men of Miletos was that they left off telling mere tales. They gave up the hopeless task of describing what was where as yet there was nothing and asked instead what all things really are now. The great epistemological principle which underlies all their thinking, though it is first put into words by Parmenides, is that *nothing comes into being out of nothing and nothing passes away into nothing.* See GREEK PHILOSOPHY; IONIAN PHILOSOPHY.

IONIAN SEA, that part of the Mediterranean Sea communicating with the Adriatic Sea or Gulf of Venice by the Strait of Otranto, and having Greece and part of Albania on the east, Sicily and part of southern Italy on the west. This sea, divided from the Adriatic Sea by a submarine ridge rising in the Strait of Otranto, has a shoal or submarine ridge, already referred to by Strabo, which joins Sicily and Tunis, as the true geological boundary of its basin on the west. Over this shoal the waters of the Mediterranean do not rise much more than 100 fathoms, a narrow flood connecting two divisions of the main sea. Its greatest breadth is between Cape Passero in Sicily and Cape Matapan in the Morea, which is about 400 miles. This waste of water washes all the shores of the Ionian Islands excepting those of Cerigo. From the more elevated spots in one of these historic islands the prospects are magnificent. From the high places in Corfu the view takes in two seas, and in clear weather one may discover the faint line of the Italian coast, near the city of Otranto, more than 70 miles away.

Dry cold winds passing over the snows upon the Albanian hills and those of Greece impart to the islands and the surrounding Ionian Sea a chill more piercing-cold than is common even in regions more to the north. The sirocco of southeast wind blows over the sea and its isles during 126½ days annually.

The deepest points in the whole stretch of the Mediterranean waters have been found to lie beneath the surface of the Ionian Sea. Near its centre, say about 36° N. and 18° W. of Greenwich, soundings reveal 2,170 fathoms of water. Then due south of the land of the Morea there is an abrupt fall, in about 36° N., and the greatest depth beneath the surface of the whole watery surface of the Mediterranean is found to lie. The Gulf of Taranto and Squillace, washing the shores of Italy, and the Gulf of Arta, Patros and Arcadia on the coasts of Greece, are among the more important inlets of the Ionian Sea. And the Gulf of Patros is connected with the waters of the historic Gulf of Lepanto. The ebb and flow of tides so marked at Venice are on the whole little perceptible on the shores of the Ionian Sea. In some places it does not rise an inch.

The origin of the Roman designation, Ionium Mare, is very doubtful. The term is found first in the works of the poet Æschylus, who died 456 B.C., though exactly what meaning he attaches to it cannot be clearly ascertained. By this poet, and the ancients generally, the name is usually derived from the "sore-wasting" wanderings of Io, daughter of Inarchus, the river-god of Argos, and its first king. But it is more probable that the sea obtained its name from the Ionian colonies which settled the island of Cephallenia in the Ionian Sea, along with other islands off the coasts of Greece in the same locality. According to Theopompus, Strabo tells us, the name "Ionian" itself was derived from an ancient chieftain's name, Ionius, a native of ancient Issa, now Lissa, a small island in the Adriatic Sea. Pliny, Mela and Tacitus use the words Ionium Mare. Ptolemy, *Ιονιον πελαγος*; Ovid, Ionium Æquor; Horace, Ionium Sinus,—all words equivalent to Ionian Sea. Herodotus, born 484 B.C., and Thucydides, born 471 B.C., both talk of the Ionian Gulf, which as they describe it can only mean the Adriatic Sea of to-day. Strabo, born 64 B.C., appears to have used Ionian Gulf in the same way. Herodotus also alludes to the Ionian Strait, indicating by that term the modern Strait of Otranto. In course of time a wider but vague and indefinite meaning was attached to Ionian Sea. It is perhaps in the works of Polybius, born 204 B.C., that one meets with these words employed in a way approximating most nearly to modern usage. He employed them, however, in a narrower sense than a modern would, to indicate that part of the Mediterranean Sea extending from the entrance of the Adriatic southward to the Peloponnesus, now the Morea. At a later time Pliny, born 23 A.D., included under the term both the Sicilian and Cretan seas besides the modern Ionian Sea. Later still all these arbitrary divisions of the Mediterranean were merged in the extension of the term "Adriatic" which comprised them all. The modern usage of the term Ionian Sea has already been explained. In its ancient and widest signification Ionium Mare must at one time have been understood to mean not the seas of Sicily and of Crete, but even also the far-away waters of the ancient Icarian Sea, a sheet of water nowadays always considered as a part of the historic Ægean.

In modern times many keels have stirred the dark blue waters of the Ionian Sea. From the island of Malta branch out in many directions different steamship routes. From this island one may embark for Brindisi, Patros, Constantinople, Beyrout, Port Said, Alexandria and Bengazi—all of which ship-lines pass over the Ionian Sea. The route from Naples to Athens involves a passage over it. The trip from Athens to Tripoli includes it. And the voyage from Port Said to Brindisi runs through it. Cable lines dropping down into its greatest depths likewise connect its shores. The main among these begin at Malta and unite that island with Zante, Athens, Alexandria and Tripoli.

IONIC DIALECT. See GREEK LANGUAGE.

IONIC ORDER, a style of architecture, so named from the district of Ionia, in ancient Greece, where it originated. Its most marked difference from other orders is seen in the capital of the column, in which spiral ornaments or volutes predominate. From the Doric it also differs in providing a base for the column. A dentil band on the cornice is also proper to the Ionic, in which it was first employed. These Ionic peculiarities appear to be of Eastern origin, probably Assyrian, as is indicated by the employment of the honeysuckle ornament so frequently met with there. Excellent examples of this style are the temple of Fortune at Rome, that of Minerva Polias and that of Erechtheus in Athens.

IONIC THEORY, another name for the Arrhenius Electrolytic Dissociation Theory. For further discussion of this theory the reader is referred to the articles on ARRHENIUS; ELECTROLYSIS; SOLUTIONS.

IONIZATION. See ELECTROLYSIS; ELECTRON; SOLUTION.

IONTOPHORESIS. See ELECTROTHERAPEUTICS.

IORGA, yor'ga, **Nicolæ,** Rumanian historian: b. Botoshani, 1871. He received his education at Iashi, Paris, Berlin and Leipzig and became professor of history at the University of Bucharest in 1894. He was elected member of the Rumanian Academy in 1910. He took an active interest in politics and was soon made leader of the National Democrats. His works include 'Philippe de Mezières et la croisade au XIVe siècle' (1896); 'Notes et extraits pour servir à l'histoire des croisades' (1899–1902); 'Geschichte der Rúmänen' (1905); 'History of the Byzantine Empire' (1907); 'Geschichte des Osmanischen Reiches' (5 vols., 1907–13); 'History of Rumanian Literature in the 18th Century' (1901); 'History of Rumanian Litcrature in the 19th Century' (1902–09).

IOS, ī'ŏs, an island in the Ægean Sea, one of the Cyclades, said to have been the birthplace of Homer. According to the ancients his mother was born here, and the poet's grave was likewise located here. It is situated about 13 miles south of Naxos. The principal occupations are the cultivation of cotton, olives, wine and cattle raising. Pop. about 2,000.

I O U, a written acknowledgment of debt, usually made in this form: "To A. B. I O U Ten Dollars.—C. D. May 12, 1891." In Great Britain when the name of the creditor is stated, such a document is evidence of a debt of the amount stated due to him by the person whose signature it bears. It is not treated as a promissory note, for the reason that it contains no promise to pay. In the absence of the name of the creditor the document is *prima facie* evidence of such a debt being due to the holder of the document. It is not negotiable. The letters I O U are of course used instead of the words "I owe you" on account of the similarity of sound. In the United States it has been declared negotiable by the decisions of some courts, and it can everywhere be sued upon as an account stated without proof of the origin of the debt.

IOWA, ī'o-a ("the Hawkeye State"), a north-central State extending from the Mississippi River to the Missouri River, and occupying three and one-sixth degrees of latitude. It is bounded on the north by Minnesota, on the east by Wisconsin and Illinois, on the south by Missouri, and on the west by Nebraska and South Dakota. Area, 56,025 square miles; 550 water; it is 310 miles east and west, and 210 north and south. Capital, Des Moines. Pop. 1910, 2,224,771; 1920, 2,404,021. It is the 16th State in order of admission to the Union, following the organization of the original 13 colonies as States.

Topography.— Iowa is a part of the great central plain, and is chiefly undulating prairie, rising in gentle swells from the Mississippi River to a divide running diagonally, from a height of 1,694 feet in the northwest to a slight elevation in the southeast, with a parallel subdivide in the southwest. There are now no swamps and few natural forests. The only rough spots are the sharp bluffs where the rivers have cut their paths through the glacial drift; the only woods, those along the streams — altogether about 7,000 square miles of woodland, with oak, elm, hickory, black walnut, maple, cottonwood, linden, ash, box-elder, pine, cedar, etc. The eastern watershed, two-thirds of the whole State, is drained to the Mississippi by a series of streams, nearly all of which are parallel and have a southeastward course. The western part is drained to the Missouri by shorter and swifter rivers, flowing first southwest and then south as the Missouri turns eastward. The chief Mississippi affluents are the Upper Iowa, the Turkey, the Maquoketa, the Wapsipinicon, the Iowa and the Cedar (the "main" stream, the Iowa — 375 miles, its "tributary," the Cedar, 400 miles, the two forming the second largest interior system of the State and joining not far from the mouth of the Iowa), the Checaqua, or Skunk, and lastly the Des Moines with its numerous affluents, far the greatest and commercially the most important as well as the finest scenically, rising in Minnesota and running diagonally across the entire State in a course of 550 miles, with a basin of 14,500 square miles. The State is prolonged by a southeastern corner to include the entire channel of the Des Moines. The northern part of the State has a continuation of the many small, clear, pebbly lakes of Minnesota in glacier-scored pits; some of them — the Walled Lakes — surrounded each by a natural wall of loose stones. The largest are Spirit Lake and the two Okoboji lakes in Dickinson County, and Clear Lake in Cerro Gordo County, all popular summer resorts. West Okoboji, of great depth, lies between wooded hills, and is indented by several picturesque "points" or promontories.

Climate.— The winter climate is somewhat severe because of the location of the State in the midst of a great continent, such severe winters being experienced in all mid-continental climates in middle and northern latitudes. The severity is tempered by freedom from excessive moisture. The State is one of the healthiest in the Union, several of the streams in the northeast having rocky channels, and none having the miasmatic bottom-lands found farther south. The dry, pure air of its rolling prairies affords a valued sanatorium for consumptives. The average annual temperature is 47.4°. The average monthly temperature ranges from 18° in January to 74° in July. The absolute range of temperature during the 26 years of record — 1890 to 1915, inclusive — is 160°, the highest being 113°, in July, 1901, and the lowest 47° below zero, in January 1912. The average precipitation, rain and melted snow, is 31.97 inches, of which 80 per cent falls during the seven months, April to October, inclusive, and more than 52 per cent of the annual amount falls during the critical crop months, May to August, inclusive.

Geology.— No less than five separate sheets of glacial drift cover the State, giving a remarkable variety of productive soil, as well as clays for industrial purposes. The underlying rocks are inclined from northeast to southwest over the greater part of the State, and many of them outcrop in the eastern part of the State in lines which extend from northwest to southeast. The oldest formation is the Sioux Quartzite, which is exposed in the northwestern corner. In the eastern and southern parts of the State from northeast to southwest are found Cambrian, Ordovician, Silurian, Devonian and Carboniferous in succession. Cretaceous deposits overlie the older formations generally through the northwest part.

Minerals.— Among the States of the Union, Iowa ranked 25th in the value of mineral products in 1919. The total value of the mineral products in that year was $18,473,558. This value was increased to $57,250,480 in 1920 and dropped to $35,693,505 in 1921. Ranked according to value of products, the leading mining industries in 1919 were coal mining, gypsum mining, limestone quarrying and clay mining. Coal produced during the year had a value of $16,903,358. In 1920 the State produced 7,813,916 short tons of coal valued at $30,794,000; in 1921, 4,531,392 tons valued at $17,256,800; in 1922, 4,500,000 tons. The coal-producing area of the State is part of the Western Interior Coal Field and extends over 20 central and western counties. Gypsum produced in 1921 totaled 350,247 short tons valued at $2,922,700 as compared with 571,895 tons valued at $4,422,965 in 1920. Clay products in 1921 had a value of $5,711,583 as compared with $10,439,957 in 1920. Limestone of a fine grade is quarried in the State, the value of the 1921 product being $516,730. Sand and gravel produced in 1921 amounted to 2,641,982 short tons valued at $1,726,958 as compared with 2,467,644 short tons in 1920, valued at $1,993,441. Considerable mineral water also is produced, Colfax Springs being widely known.

Agriculture.— Iowa is unsurpassed in the quality and extent of cultivated land. It presents mainly a friable black loam on the top, from one to five feet deep; is easily worked, is in the main free from stumps and stones, and requires little commercial fertilizer. It has three main varieties, the principal being the alluvial mud of the river bottoms, the glacial drift of the prairies, covering most of the State, a sand and clay loam, and the loess, a rich yellow deposit containing much carbonate of lime, found at great depth on the Missouri slope and along the streams in the central and eastern portions. There is now almost no waste land in the State. In 1919 the number of acres included in farms was 33,474,896 — a decrease

of 455,792 in 10 years, the decrease largely due to growth of cities, suburban residences and parks and a steady increase in the area of timber land. With remarkable fertility and a steady and sufficient rainfall, the State has for many years been first in the Union in value of its products derived exclusively from the soil. The total number of farms in the State in 1920 was 213,439 as compared with 217,044 in 1910, a decrease in 10 years of 3,605 or 1.7 per cent. Improved land in farms totaled 28,606,951 acres in 1920 as compared with 29,491,199 acres in 1910, a decrease in 10 years of 884,248 acres or 3 per cent. Woodland in farms in 1920 was 2,295,274 acres against 2,314,115 acres in 1910. The percentage of land area in farms in 1920 was 94.1 as compared with 95.4 in 1910. The average acreage per farm in 1920 was 156.8 while the average improved acreage per farm was 134. The value of all farm property in 1920 was $8,524,870,956 as compared with $3,745,860,544 in 1910. Land and buildings were valued at $7,601,772,290 in 1920 as compared with $3,257,379,400 in 1910. Land alone was valued at $6,679,020,577 in 1920 as against $2,801,973,729 in 1910. Implements and machinery owned by the farmers of Iowa were given a value of $309,172,398 in 1920 as against $95,477,948 in 1910. Livestock in the State in 1920 was valued at $613,926,268 as compared with $393,003,196 in 1910. The average value per farm of all farm property in the State in 1920 was $39,941 as compared with $17,259 in 1910; the average value per acre of land in farms (all farm property) was $254.66 in 1920 as compared with $110.40 in 1910. Land alone was valued at $199.52 an acre in 1920 against $82.58 in 1910. Farm expenditures for labor in 1919 totaled $70,698,060 as compared with $24,781,592 in 1909; expenditures for fertilizer in 1919 amounted to $596,537 as compared with $109,570 in 1909; expenditures for feed in 1919 totaled $79,068,535; in 1909, $18,582,251. In 1920 mortgaged farms in the State numbered 66,096 as compared with 68,045 in 1910. The mortgage debt in 1920 was $489,816,739 as compared with $204,242,722 in 1910. Corn is the leading crop of the State. The yield in 1919 was 371,362,393 bushels valued at $501,339,232 compared with the 1909 crop of 341,750,460 bushels valued at $167,622,834. The yield in 1922 was 455,535,000 bushels, grown on 10,123,000 acres and valued at $255,100,000. The acreage in 1919 was 9,006,733; in 1909, 9,229,378. The next most important crop is oats. The yield in 1919 was 187,045,705 bushels, grown on 5,484,113 acres and valued at $140,284,289 as compared with the 1909 crop of 128,198,055 bushels grown on 4,655,154 acres and valued at $49,046,888. The oat crop of 1922 amounted to 222,851,000 bushels grown on 6,023,000 acres and valued at $77,998,000. The wheat crop of 1919 amounted to 21,591,928 bushels grown on 1,437,743 acres and valued at $44,479,372 as compared with the 1909 crop of 8,055,944 bushels grown on 526,777 acres and valued at $7,703,205. In 1922 Iowa produced 16,867,000 bushels of wheat on 757,000 acres which had a value of $16,699,000. Barley grown in 1919 totaled 5,352,802 bushels raised on 236,314 acres and valued at $6,423,366 as compared with the 1909 crop of 10,964,184 bushels grown on 571,224 acres and valued at $5,320,708. In 1922 the State produced 4,260,000 bushels of barley from 150,000 acres which had a crop value of $2,087,000. The hay crop of 1919 amounted to 4,645,292 tons valued at $95,945,313. The 1922 crop was estimated at 4,750,000 tons valued at $47,500,000. In 1919 Iowa produced 4,438,515 bushels of potatoes valued at $10,874,361. In 1922 the crop was estimated at 8,460,000 bushels valued at $5,668,000. Orchard fruits produced in 1919 totaled 2,020,520 bushels valued at $4,414,000 as compared with 7,234,168 bushels valued at $4,283,873 produced in 1909. The value of dairy products sold in 1919 was $45,362,250 as compared with $26,429,743 in 1909. The total value of all farm crops in 1919 was $880,391,299 as compared with $309,376,240 in 1909.

Livestock and Poultry.— Domestic animals on the farms in Iowa in 1920 were valued at a total of $585,489,568. These included 1,386,522 horses valued at $127,297,231; 81,520 mules valued at $10,041,522; 3,038,198 beef cattle valued at $172,373,106; 1,519,510 dairy cattle valued at $86,304,857; 1,092,095 sheep valued at $12,883,597; 10,526 goats valued at $59,594, and 7,864,304 swine valued at $176,264,026. On 1 Jan. 1923 there were on the farms in the State 1,305,000 horses valued at $103,095,000; 101,000 mules valued at $8,080,000; 1,160,000 milch cows valued at $67,280,000; 3,479,000 other cattle valued at $122,461,000; 829,000 sheep valued at $6,964,000, and 9,615,000 swine valued at $123,072,000. Chickens on farms in 1920 numbered 27,746,510; eggs produced totaled 117,908,389 dozen valued at $41,709,116.

Manufactures.— The State's fast-growing population and prosperity and its abundant and almost inexhaustible supply of bituminous coal have, together, within the last decade given a rapid impetus to manufacturing. Small factories have enlarged and many new factories have sprung up. Not a few of these are assuming large proportions. Iowa's manufactured products in 1914 aggregated $310,750,000, an increase of 93.5 per cent over the total in 1904. In 1919 the manufactured products of the State were valued at $745,472,697 a gain over 1914 of 139.9 per cent. During the five years, 1914–19, the wages in Iowa factories have increased 126.1 per cent; the number of employees has increased 27.6 per cent and the number of factories has increased 1.2 per cent. Factories, 5,683; wage-earners, 80,551; total of wages in 1919, $90,117,169. The products of the 30 slaughtering and meat-packing establishments in the State in the year 1919 were valued at $226,865,000. They gave employment to 7,197 persons, their wages aggregating $8,811,000. The butter, cheese and condensed milk industry numbers 434 establishments, their products valued at $57,800,000. There are 849 foundry and machine shops, employing 9,022 persons, their wages totaling $10,968,000; their products valued at $48,994,000. There are 997 printing and publishing establishments with 4,808 employes, their wages aggregating $5,134,000, their products valued at $26,806,000. There are 189 flour and grist mills employing 590 wage-earners at wages totaling $578,000 and turning out products valued at $21,325,000. Artificial stone plants number 255, which employ 672 persons, pay out $734,000 in wages and turn out products valued at $2,962,000. Button-making establishments number 77, pay wages totaling $1,519,000

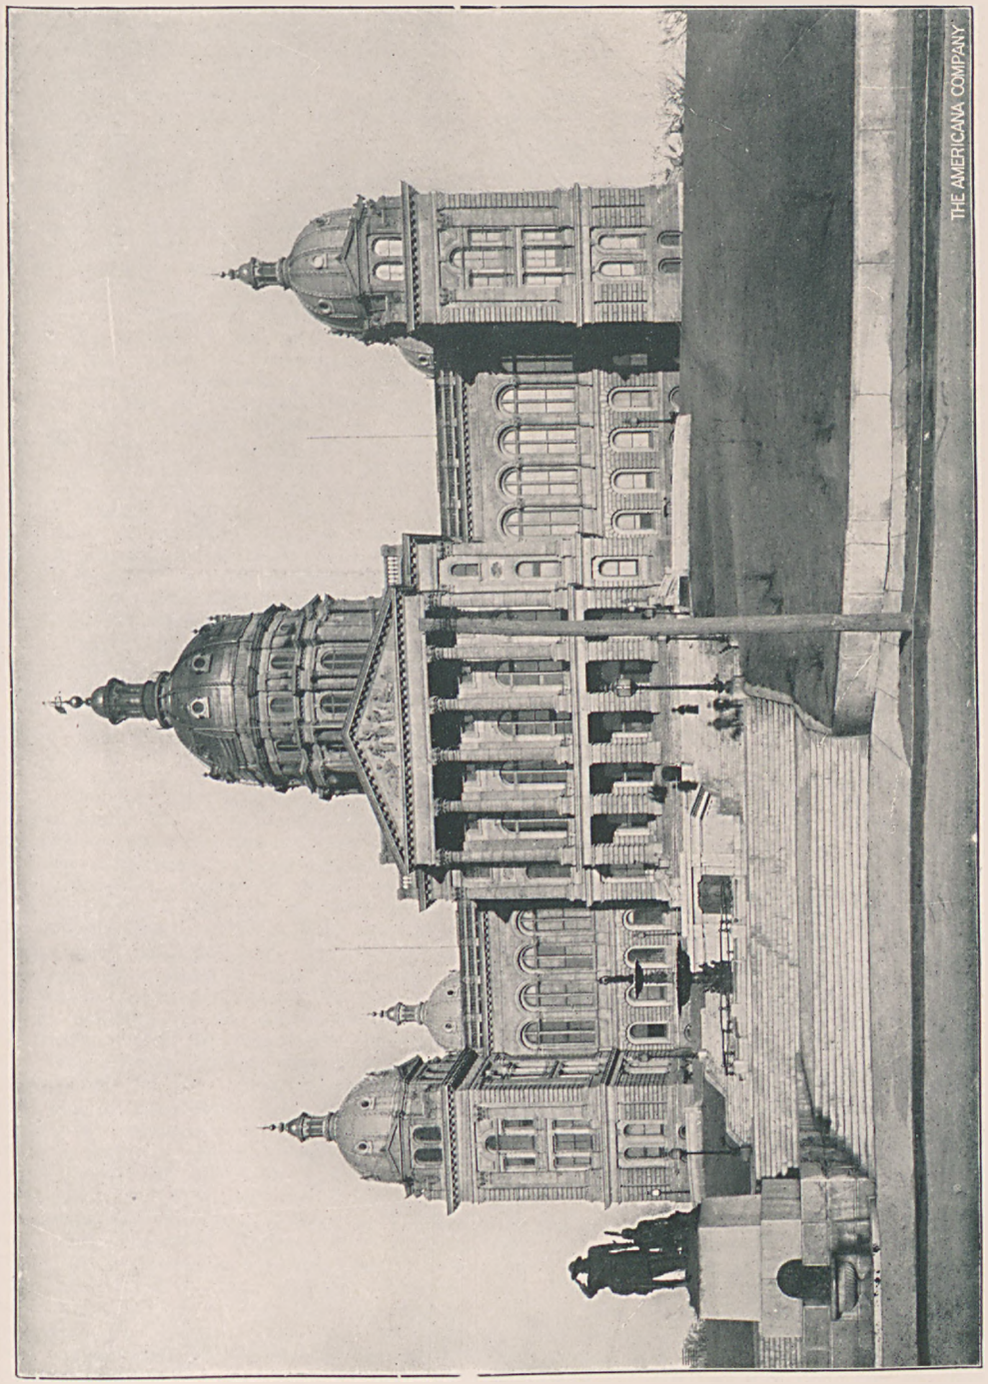
to 2,091 workmen and turn out products valued at $5,615,000. Men's clothing and shirts, with 22 plants, and 778 employes turn out products valued at $3,858,000, while 10 establishments making women's clothing employ 503 persons and turn out products valued at $2,069,000. There are 120 copper, tin and sheet-iron works which employ 803 wage-earners and turn out products valued at $5,062,000. Other industries include 68 gas, illuminating and heating plants with 727 employees and products valued at $5,738,000; 114 plants making patent medicines and compounds, and druggists' preparations which employ 746 wage-earners and turn out products valued at $10,658,000; 76 canning and preserving plants employing 1,582 wage-earners and producing products valued at $10,223,000; 144 establishments turning out lumber and timber products valued at $17,893,000 and employing 3,549 wage-earners, and 26 establishments making agricultural implements which employ 906 wage-earners and turn out products valued at $5,959,000. These turn out cultivators, equalizers, harrows, hoes, plows, seeders, drills, harvesters, hay-carriers, hay-forks, horse hay-rakes, manure spreaders, separators, etc. Among the larger cities, Des Moines leads in brick-making, proprietary medicines, book and job printing and binding, and hosiery; Sioux City, Ottumwa, Cedar Rapids and Des Moines in meatpacking; Davenport, Dubuque, Burlington, Des Moines and Ottumwa in foundries and machine works; Dubuque, Council Bluffs, Grinnell and Des Moines in carriages; Burlington, Davenport, Des Moines, Dubuque, Ottumwa, Keokuk and Oskaloosa in cigars; Sioux City, Des Moines, Cedar Rapids, Fort Dodge, Mason City, in flour and other food products; Des Moines, Ottumwa, Grinnell, Newton, Fairfield and Fort Madison in farm and other machinery.

Transportation and Commerce.— Several of the interior rivers are navigable for small boats, the Des Moines for 100 miles, the Missouri for fair-sized steamers its whole length, and the Mississippi for large ones to Saint Paul. But steamers have, in the main, been superseded by railroads; the shifting channel, sand bars and snags of the Missouri make its navigation dangerous and slow. Only the Mississippi remains in practical use. The State, lying in the main path of transcontinental commerce, and originating much well-distributed local traffic, is a vast network of railroads, seven of the great trunk lines crossing it. Every one of the 99 counties has at least one railroad. The farthest distance between railroads at any point in the State is 13.79 miles. Iowa has 9,809.09 miles of steam railroad and 963.32 miles of interurban. There is a rapid but steady increase in the mileage on interurbans. The chief cities of interurban lines are Des Moines and Cedar Rapids.

Banking.— Iowa has the second largest number of banks of any State in the Union. On 30 of June 1922 there were in Iowa a total of 1,774 banks with resources aggregating $1,126,086,000, paid-in capital amounting to $83,704,000 and individual deposits aggregating $821,799,000. Their surplus totaled $43,490,000. National banks numbered 351 with resources totaling $363,828,000, paid-in capital amounting to $26,025,000 and individual deposits aggregating $224,582,000. In 1905 there were but 281 National banks in the State and these had paid-in capital amounting to $17,665,000. In 1922 there were 403 State banks in Iowa. These had resources aggregating $229,347,000, paid-in capital totaling $18,886,000 and individual deposits amounting to $174,189,000. State banks in 1905 numbered 248 with paid-in capital of $10,625,800 and deposits totaling $46,261,287. Trust companies in 1922 numbered 21 with resources aggregating $35,522,000, paid-in capital totaling $4,560,000 and individual deposits of $23,609,000. Saving banks increased from 429 in 1905 to 908 in 1922, in capital from $13,471,000 to $32,469.000 and in deposits from $100,232,071 to $358,328,000. Private banks decreased from 139 in 1905 to 91 in 1922. Their capital decreased from $3,045,166 to $1,764,000. Their deposits in 1922 totaled $41,091,000.

Insurance.— Iowa's insurance corporations are many and extensive, their operations extending to all parts of the Union. While life insurance is the larger interest, fire and casualty companies are growing in number and volume of business. At the beginning of the year 1916 its fire organizations were: stock companies, 4; mutual companies, 3; State mutual associations, 31; county mutual associations, 160. The seven companies show assets amounting to $4,674,867 and net premiums received $2,347,533.64. The 31 State mutual associations show assets, $2,406,510.82; income $1,708,291.61. The 160 county mutual associations show assets $1,502,400.05; income $1,167,718.39. At the beginning of the year 1916, combined assets of Iowa's six casualty companies $2,101,368.43; income $1,173,618.38. At the beginning of the year 1916 there were 14 Iowa companies, 3 Iowa associations and 12 fraternal societies engaged exclusively in life insurance. Of the 14 Iowa life insurance companies, the total assets at the beginning of 1916 was $53,524,298.10; total income $19,148,606.28; of the three associations the total assets at the beginning of 1916 were $3,536,518.80; total income $2,222,531.04. Of the 12 fraternal societies, the total income was $7,439,498.10.

Education.— In 1910 Iowa ranked second among the States in literacy, with 1.7 per cent of illiterates; in 1920 it regained its first place, with only 1.1 per cent of illiterates. These figures are doubly significant when given in connection with the fact that, by the last Federal census, the average of illiteracy in the United States is 6.0. In 1910 there were 29,889 illiterates in the State; in 1920 there were 20,680. Attendance on common schools in 1920, 71.2 per cent; attendance on high or preparatory schools, 10.1 per cent. Its total expenditure for schools and colleges in 1921 was $59,068,023. In 1920 the number of children of school age (between five and 20 years) in the State of Iowa, according to the Fourteenth Census of the United States was 724,452. Of these 515,616 or 71.2 per cent were reported as attending school. The daily average attendance for 514,521 pupils out of 597,914 between the ages of five and 18 years was 405,567; the average duration of schools was 177 days; the number of teachers employed was 27,660—2,265 males and 25,395 females; the salaries paid teachers totaled $20,219,013 and the total expenditure for schools was $37,334,167. The number of children attending the 677 public high schools in the State was 21,922 males and



State Capitol at Des Moines

31,694 females. Public high school teachers numbered 875 males and 2,547 females. Teachers in 99 private high schools and academies numbered 111 males and 359 females; pupils, 1,404 males and 3,417 females. Twenty-three universities, colleges and schools of technology in the State reported professors and instructors to the number of 847 males and 398 females. The total receipts of these institutions, exclusive of additions to endowments, was $5,769,328. Students in the preparatory departments numbered 1,290 males and 919 females; students in collegiate departments numbered 4,632 males and 5,201 females. Graduate students numbered 333 males and 276 females. There were reported in the State in 1920, four schools of theology with 105 students; two schools of law with 287 students; one school of medicine with 244 students; one school of dentistry with 312 students; one school of pharmacy with 67 students and one school of veterinary medicine with 108 students. The number of students reported as enrolled in vocational schools in the State in 1921 was 824 divided as follows: males, 267; females, 557. In 1920 the Iowa State Teachers' College was reported as having 75 male and 84 female teachers and 374 male and 3,767 female students. Under the Iowa plan of training teachers for rural schools, the teacher in training at the Iowa State Teachers' College is excused from her work in college for one month and goes to live in the rural district where she is to learn to teach a rural school. But one teacher in training is assigned to a school at a time. The teacher is responsible only for eight weeks of college credit during the 12 weeks' term in which she does her teaching. She works beside the regular teacher in the rural school as assistant and is assigned a regular schedule of observation, classroom teaching, helping with seat work, supervising the noon lunch and playground activities and taking part in evening community meetings. A part of her assignment is to get acquainted with parents who have children in school in order that in one month's time the strongest possible bonds of sympathetic understanding and mutual confidence may be established with the patrons. The teacher in training is usually assigned as instructor to about one-third of the classes on the daily program of the rural school. She is constantly under the supervision and guidance of the regular teacher, who is an expert critic selected by the Teachers' College and paid in part by the college.

Among the important institutions of higher learning in the State are the Iowa State College of Agriculture and Mechanic Arts, at Ames (coeducational); Coe College at Cedar Rapids (coeducational); Wartburg College at Clinton (men); Saint Ambrose College at Davenport (men); Luther College at Decorah (men); Des Moines University at Des Moines (coeducational); Grand View College at Des Moines (coeducational); Drake University at Des Moines (coeducational); Columbia College at Dubuque (men); University of Dubuque at Dubuque (coeducational); Mount Saint Joseph College at Dubuque (women); Parsons College at Fairfield (coeducational); Upper Iowa University at Fayette (coeducational); Grinnell College at Grinnell (coeducational); Lennox College at Hopkinton (coeducational); Simpson College at Indianola (coeducational); State University of Iowa at Iowa City (coeducational); Ellsworth College at Iowa Falls (coeducational); Western Union College at Le Mars (coeducational); Iowa Wesleyan College at Mount Pleasant (coeducational); Cornell College at Mount Vernon (coeducational); Penn College at Oskaloosa (coeducational); Morning Side College at Sioux City (coeducational); Buena Vista College at Storm Lake (coeducational); Tabor College at Tabor (coeducational); Central Holiness University at University Park (coeducational), and Central College at Pella.

Libraries.— Iowa had 131 free public libraries in 1916. Eighty-eight of these in as many different cities and towns occupied buildings erected by Andrew Carnegie, and in 1916 eleven others were in process of erection. There is only one endowed free public library in the State, the Kendall Young library in Webster City. The State has 31 college and academy libraries, also 14 in State institutions under the board of control, and eight in other State institutions; 50 association and subscription libraries, and four miscellaneous, making a total in the State of 239. The total number of volumes in the public libraries of the State in 1916 was 1,126,073. In the association libraries, 59,508. In institutional libraries under the board of control, 39,225. In other State institutions 437,647. In colleges and academy libraries, 300,103. Total of volumes in the libraries of the State are 1,962,556.

Churches and Church Membership.— There were in 1915, 4,218 church organizations in Iowa, a gain of 397 in 10 years; membership in 1915, 928,417, a gain of 346,577 in 10 years; value of church property in 1915, $47,717,451, a gain of $22,894,852 in 10 years. The principal denominations show the following membership in 1915: Methodist, 325,959; Catholic, 206,701; Lutherans, 107,523; Disciples of Christ (Christian) 60,720; Presbyterian, 47,059; Baptist, 39,321; Congregationalist, 35,538; United Brethren, 10,366; Latter Day Saints (monogamous) 10,216; United Presbyterian, 9,049; German Evangelical Synod, 8,084; Christian Scientists (estimated) 7,500; Protestant Episcopal, 7,233; Friends, 6,629; Evangelical Association, 5,236. Other denominations: Adventists, Dunkers, United Evangelical, Jews, Mennonite bodies, other Methodist bodies, Reformed bodies (Bohemian, etc.), Salvation Army, Unitarians, Universalists, etc.

Charities and Penal Institutions.— Iowa has 17 institutions under a board of control, in which over 10,000 persons are cared for by the State; six for correction and reformation, viz: one penitentiary, two reformatories, two industrial schools, one custodial or convict farm; four hospitals for the insane; one for tuberculous patients; one for epileptics; one for victims of drugs and intoxicants; one home for soldiers and sailors and their wives; one school for the deaf; one home and school for orphans; one home for the mentally deficient. In 1916 the hospital for epileptics was nearing completion, the custodial farm was in partial use, and the reformatory for women was in process of equipment. The inmates of these 17 institutions increased in number from 8,312 in 1906 to 9,309 in 1914. The cost of maintenance has

increased from $1,893,590—or $179.48 per capita—in 1906 to $4,545,468—or $400.93 per capita—in 1914. The State has 10,397.05 acres of land in use with these institutions, as against 4,189 acres in 1898 when the board of control assumed their management. The property was then appraised at $8,380,718; its appraisal value in 1915 was $12,487,150.44.

State Government.—The constitution was adopted in 1857. By law, the electors must vote once in 10 years on calling a convention to revise the constitution, which convention the legislature must call if so voted. All amendments must receive a majority vote of both houses in two successive legislatures, and then be passed by popular vote. The only amendment to the constitution since 1857 was in 1868, when the word "white" was eliminated. The proposed amendment extending the suffrage to women was voted down 5 June 1916 by a majority of 10,341. An amendment prohibiting the sale of intoxicating liquor as a beverage was carried in 1882 by a majority of 29,759, but was declared invalid by the Supreme Court. An amendment to the same effect was submitted in 1915 and 1917. On 15 Jan. 1919, both houses of the General Assembly—by a vote of 42 to 7 in the Senate and 86 to 13 in the House—passed a joint resolution ratifying the prohibitory amendment to the Constitution of the United States, thus summarily disposing of the question. The Senate has 50 four-year members, the House 108 two-year members; legislative sessions are held biennially in the odd-numbered years. Bills must have a majority of all members elected to both houses—not merely present. A two-thirds vote overcomes the governor's veto. Executive officials are elected for two years—half in one year and half in the alternates, with the exception of the railway commissioners, who are elected for three; the railroad commission has power to regulate rates, etc. The judiciary consists of a Supreme Court, with a chief justice who is such by reason of priority of election, six associate judges, chosen every year; also 53 district judges in 20 districts, each serving four years.

Until the enactment of the 19th amendment to the Federal Constitution women could vote only on school questions involving the expenditure of money, and on municipal questions involving the issuance of bonds.

Under the law all incorporated towns of 2,000 people and over are ranked as cities; all platted but unincorporated towns are villages. The number of representatives in Congress is 11. In politics the State has been Republican since the organization of the party, except in the years 1890–94, when the advocacy of prohibition drove it into retirement. The prohibitory amendment, adopted in 1882 and pronounced unconstitutional by the Supreme Court of the State, was succeeded by prohibitory laws which after several years' trial were in turn succeeded by a local option law under which 54 of the 99 counties of the State were reported in 1903 as wholly free from saloons. In 1915 the local option law was repealed, leaving the entire State under a prohibitory law.

Finances.—The finances of the State for the period beginning 1 Jan. 1922 show the following: Balance in the treasury on that date $3,407,223. Revenue from all sources during the year aggregated $22,248,148. Expenditures for the same period amounted to $22,679,498. Balance 1 Jan. 1923 $2,975,873. The State has no bonded debt. The assessed value of all real property in 1922 was $3,627,532,791. Personal property in the same year was assessed at $671,101,604. Local taxation is limited to 1 per cent of valuation for current expenses, but this may be exceeded for waterworks, sewers, schools, etc. The State cannot incur a debt of more than $250,000 except for war purposes. Counties and towns cannot incur a debt of over 5 per cent of their actual valuation.

In 1920 the aggregate assessed value for taxation purposes of the railroads in the State was $78,525,658; interurban lines were assessed at $2,184,354 and sleeping cars at $372,334. The property of express companies was assessed at $308,399.10. The assessment of equipment car companies for taxable purposes was $328,290 and the amount of taxes paid by them was $21,736.08. Telephone and telegraph lines were assessed at $791,859.12 for telegraph lines: $131,941.50 for toll telephone lines; $135,302 for telephone exchanges; $4,612,195 for mixed commercial telephone companies including exchanges, rural and toll telephones and $343,135 for rural telephone lines.

The section of the Constitution limiting the State debt to $250,000 is to be found in Article 7 under the sub-title "State Debts" and is as follows: "The State may contract debts to supply casual deficits or failures in revenues, or to meet expenses not otherwise provided for; but the aggregate amount of such debts, direct and contingent, whether contracted by virtue of one of more acts of the General Assembly, or at different periods of time, shall never exceed the sum of $250,000; and the money arising from the creation of such debts shall be applied to the purpose for which it was obtained, or to repay the debt so contracted, and to no other purpose whatever." In addition to the above limited power to contract debts the State may contract debts to repel invasions, suppress insurrection or defend the State in war. Every law which imposes, continues or revives a tax shall distinctly state the tax and the object to which it is to be applied; and it shall not be sufficient to refer to any other law to fix such tax or object.

Population and Divisions.—Iowa in 1920 ranked 16th among the States in population. The population was 43,112 in 1840; in 1850, 192,214; in 1860, 674,913; in 1870, 1,194,020; in 1880, 1,624,615; in 1890, 1,911,896; in 1900, 2,231,853; in 1910, 2,224,711; in 1920, 2,404,021. The original population was part of the Free-State movement which peopled the Central States. Of the entire population (1920), 225,647 were foreign-born. Of these 70,642 were from Germany; 57,857 from Scandinavia, or nearly three-fifths from the Teutonic nations; besides several thousands from Germany, Austria and Switzerland. From England 13,036; Canada, 8,929; Ireland, 10,686; Holland, 12,471; Greece, 2,884; Italy, 4,956; Russia, 7,319; China and Japan only, 264. Total white population 2,384,181; colored 19,005. In 1920 the census showed an increase in population of 179,250 in 10 years and 172,168 in 20 years. The capital, Des Moines, on the river of the same name, is the largest city in Iowa with a population in 1920 of 126,468. On the same river to the north is Fort Dodge, an old frontier fort and settlement (19,372), and below it Ottumwa (23,303) and Keokuk (14,423). The Mississippi River business is chiefly represented, from north to south, by Dubuque (39,141) the first settled in the State, Clinton (24,151), Davenport (56,727), Muscatine (16,068), Burlington (24,057), Fort Madison (12,066), Keokuk (14,423), the "Gate City," at the mouth of the Des Moines, Sioux City (71,227), in the extreme west, near the mouth of the Big Sioux and Council Bluffs (36,162), opposite Omaha, the old terminus of the Union Pacific, represent the Missouri River; Cedar Rapids (45,566) and Waterloo (36,230), the valley of the Cedar River; and Marshalltown (15,731), the valley of the Iowa River.*

Defense.—The State militia, or National Guard, was organized under a strict military code of the State and in harmony with the United States Army regulations. The governor is commander-in-chief, and directs the guard through the adjutant-general and staff. On 1 Jan. 1916 the guard consisted of staff departments, 6; commander first brigade and staff, 6; medical department, 176; engineer company, 72; first squadron cavalry, 299; first battalion field artillery, 415; first, second and third infantry, 2,465; first separate company, 64. Total, 3,503. In the summer of 1916 the main body of Iowa's National Guard responded to the call of the government for troops on the Mexican border, taking the national oath. In the winter of 1916–17, the Iowa troops returned to their homes but were not mustered out. On 1 March 1917 the First Iowa regiment was called to service in anticipation of the President's declaration of war with the German Empire. On 15 July following, the entire National Guard of the State was called out and sworn into Federal service, under the National Defense Act of that date. These troops rendered valiant service with the American Expeditionary Force in France, and were among the first that turned back the German advance on Paris, and their loss in killed and casualties was extensive. While every able-bodied man between 18 and 45 is subject to call as a member of the State militia, the beginning of the year 1919 found but one regiment of the Iowa National Guard, the Fourth Iowa Infantry, in existence in the State. On 31 May 1923 the Iowa National Guard had an authorized strength of 5,745; enlisted strength 3,452.

History.—The territory now included in Iowa was originally inhabited by the Ioway and Illinois tribes of Indians, which were driven out by the Sacs and Foxes. In 1761 the "Ioway" or Iowa tribes were on the east side of the Missouri River and near the headwaters of the Des Moines; but in 1805 they were occupying land on the south side of the Des Moines River. In 1846 they left the vicinity of the Des Moines, some going to the reservation of the Sacs and Foxes beyond the Missouri. The missionary, Father Marquette, and Joliet, the fur-trader, were the first white men known to have touched foot upon Iowa soil. In 1673 they landed near the mouth of the river now known as the Des Moines. In 1788 a party of 10 white men under Julien Dubuque established the first white settlement on the site of the present city of Dubuque. They were attracted by the lead deposits in the vicinity. They opened and in a small way operated mines, but after the death of Dubuque, in 1810, his associates were compelled by the Indians to abandon the settlement. All that portion of country drained by the Mississippi was claimed by France because of the explorations made by Marquette and some of his companions, and because of settlements made by other Frenchmen. France's claim to this territory was ceded by treaty to Spain in 1763, but the country was returned to France in 1800–01. In 1803 all the territory now known as the Louisiana Purchase (q.v.) was bought of France by the United States government. The territory now the State of Iowa was part of the Territory of Louisiana in 1805; of Missouri in 1812; of Michigan in 1834; of Wisconsin in 1836. Iowa became an independent territory in 1838, and was admitted as a State in 1846. The Indian claims to lands within the boundaries of the State were purchased by the United States government before its admission as a State. The last purchase was made in 1843. Remnants of the Sacs and Foxes occupy a reservation, 419 acres, in Tama County, and still receive annuities from the government. In 1832 a settlement was made at Fort Madison, an abandoned government post, and soon after Burlington was founded, and in 1830 a settlement was again made at Dubuque. In 1857 the Indians attacked the settlers living near the Okoboji lakes and Spirit Lake, in Dickinson County, and about 30 whites were killed and nearly all the houses burned. This action on the part of the Indians retarded for some years the growth of that section of the State. Burlington was first selected for the Territorial capital. Iowa City became the State capital in 1846. In 1857 the capital was removed to Des Moines. Iowa had in the Federal army during the Civil War 75,839 men, which was about one-tenth of her population. Some of this number were in regiments belonging to other States.

*The figures above are obtained from the United States census of 1920.

baugh, 'Documentary Material Relating to the History of Iowa'; Monette, 'History and Discovery of the Mississippi Valley'; Iowa Geological Survey publications; Shambaugh, 'History of the Constitutions of Iowa,' 'Messages and Proclamations of the Governors of Iowa'; Gue, 'History of Iowa'; Brigham, 'Iowa; its History and its Foremost Citizens' (1919 ed.).

JOHNSON BRIGHAM,
Librarian, Iowa State Library.

IOWA, State University of, an educational institution forming an integral part of the public school system of the State, situated at Iowa City. It was first opened in 1847, receiving control of lands given by the Federal government. (See COLLEGES; LAND GRANT). The university is controlled by a State board of education, composed of nine members appointed by the governor of the State subject to confirmation by the senate. Its work is organized in the following departments: the college of liberal arts (including the summer sessions), which offer courses leading to the degrees of B.A. and B.S.; the graduate college; the Iowa school of commerce, with both undergraduate and graduate courses; the college of law; the college of medicine; the college of homœopathic medicine; the college of dentistry; the college of pharmacy; the college of applied science and the college of education. The library, which lost 25,000 volumes by fire in 1897, now contains 125,000 volumes; the university issues the following publications: 'Natural History Bulletin'; 'The Law Bulletin'; 'The University of Iowa Studies in Psychology'; 'The State University of Iowa Studies in Sociology, Economics, Politics and History'; 'Contributions from the Physical Laboratory of the State University of Iowa'; 'Studies in Medicine'; 'Aims and Progress of Research'; 'Studies in Language and Literature'; 'Studies in Education.' The total income of the university amounts to over $3,500,000 annually, while in 1923 its property was valued at a total of $6,500,000. In 1922–23 the number of students was 6,750, the number of professors and instructors, 450.

IOWA CITY, Iowa, city and county-seat of Johnson County, on the Iowa River, and the Burlington, Cedar Rapids and Northwestern, and the Chicago, Rock Island and Pacific railroads, 54 miles west of Davenport. The city is pleasantly built on a succession of plateaus, rising one above another from steep river banks. The first plateau is laid out as a public promenade, and the third, which is about 30 feet higher than the first, is crowned by a handsome Doric edifice 120 feet long and 60 feet wide, of a beautifully marked stone quarried in the vicinity called "bird's-eye marble." This building was originally intended for the State capitol, but, on the removal of the seat of government to Des Moines, was appropriated to the State University. From 1839 to 1854, this was the seat of the Territorial and State governments. It is the seat of the State University of Iowa, the Iowa State Academy, the State Historical Society and Library, the Homœopathic, Allopathic and Mercy hospitals. It is the farming trade centre for Johnson, Cedar and Iowa counties; has excellent power provided by the Iowa River; and manufactures flour, iron, woolen goods, perfumery, gloves, jewels, fencing and linseed oil. The city has electric light and street railroad plants, waterworks on the Holly system and numerous churches. Besides its manufacturing interests the city has an extensive stock-raising and meat-packing industry. Pop. (1920) 11,267.

IOWA COLLEGE. See GRINNELL COLLEGE.

IOWA FALLS, Iowa, city of Hardin County, 50 miles east of Fort Dodge, on the Chicago, Rock Island and Pacific, the Chicago and Northwestern, and the Illinois Central railroads and on the Iowa River. Ellsworth College is situated here. The city has a Carnegie library, internal combustion engine works, drainage machinery, tile works, etc. There is a large trade in agricultural produce and in building stone. In 1914 the city-manager plan of government was put in force. Pop. (1920) 3,954.

IOWA RIVER, in the State of Iowa, rises in Hancock County, near the Minnesota State line and flows southeast into the Mississippi River, north of Burlington. It is 300 miles long, and is navigable to Iowa City, 80 miles from its mouth.

IOWA STATE COLLEGE OF AGRICULTURE AND MECHANIC ARTS, at Ames, Iowa, is a co-educational and technical institution with five main divisions of work: agriculture, engineering, home economics, industrial science and veterinary medicine. The college was founded in 1868. With campus and farms it covers 1,339 acres; the land is valued at $208,979.50; and the buildings cost $2,715,085. The college library contains over 50,000 volumes. The enrollment of students, collegiate and non-collegiate for 1922–23, including the summer and winter sessions was 7,096. The college bases its strongest claim to success as an educational institution on the work of its graduates in their vocations throughout the United States and the world. The college is supported by Acts of Congress known as the Morrill Acts (1862 and 1890). The property of the college in 1923 was valued at $5,818,686.57 and its income was $3,052,557.16.

IOWA WESLEYAN COLLEGE, Mount Pleasant, Iowa, a coeducational institution founded in 1844 under the auspices of the Methodist Episcopal Church. Admission is nonsectarian. The faculty numbers 26; the average annual attendance of students is 500; tuition fees amount to 90; living expenses to $300. The productive funds total $650,000; the annual income including tuition fees and incidental charges is $32,085. There are over 12,000 volumes in the library. The number of graduates since organization is 1,058. The college colors are white-purple.

IOWAS, a tribe of American Indians of the Algonquin family. In 1800 the Iowas lived in Minnesota and soon after moved southward. They were called Palinchas, or "Dusty Noses," in their own tongue. Lewis and Clark, the explorers, designate them as the Ayanways, and the early French traders called them the Ajowes. In 1836 they moved to the Wolf River region west of the Mississippi, and in 1861 ceded 16,000 acres of land to the United States. The remnants of the tribe, less than 500 in number, at present live on reservations in Oklahoma and Kansas. (See also INDIANS, AMERICAN; IOWA).

Consult Miner, W. H., 'Iowa Indians: A Sketch of their History' (Cedar Rapids, Iowa 1912).

IPECAC, or **IPECACUANHA,** a South American plant of the order *Rubiaceæ* variously called by botanists *Cephælis ipecacuanha* and *Psychotria ipecacuanha.* The plant, which is found mainly in moist shady forests in Brazil, is a creeping herb or sub-shrub with mostly bare stems, only the extremities producing leaves. The small white blossoms, which are borne in heads with long stalks, are followed by dark purple berries. The rather fleshy more or less divided roots were in medicinal repute among the South American Indians, and gradually found their way into European medicine under the name "ipecacuanha." They have been considered emetic, nauseant, diaphoretic and expectorant, and in large doses are poisonous. They appear in commerce in various grades (gray, brown and red), which are dependent mainly upon the season at which they are gathered, the way they are dried, the age of the plants, etc. The chief supplies are collected during January, February and March by the Indians. Owing to the slow growth of the plant and the low price the roots command, ipecac is not cultivated commercially; it has, however, been successfully grown in various parts of the world. It is a constituent of Dover's powder. The roots of several other plants are substituted for those of true ipecac among the best known being those of *Tylophora asthmatica* and *Sarcostemma glaucum* (Venezuelan ipecac), both of the natural order *Asclepiadaceæ.* Other species of *Psychotria* and certain species of *Richardsonia* are similarly but unofficially employed.

Wild or American ipecac (*Gillenia stipulacea*) of the rose family, is a common plant in the southeastern United States and as far north as western New York. It is a perennial herb about three feet tall, bearing paniculate corymbs of white or pale rose colored flowers. It is hardy, of simplest culture and being graceful is frequently planted for ornament in flower borders where the soil is of good quality.

IPEK, Montenagro, town situated on the White Drin (Bitritsa), near the Serbian frontier. It is famed for its ancient monastery, founded in the 13th century and until 1690 the seat of Patriarchs of Serbia. The town is well built. Silk is raised and spun in considerable quantities and fire arms are manufactured. Until 1913 the town was in Turkish territory, in the vilayet of Kossovo and sanjak of Novibazar. Pop. 10,500, mostly Serbs and Albanians.

IPHICRATES, ī-fĭk'ra-tēz, Athenian commander: b. and d. in the 4th century B.C. Of humble origin, he raised himself to eminence by his courage and talents. In the war of Corinth (393–92 B.C.) he opposed with success Agesilaus, the warlike king of Sparta. He was sent to the Hellespont to act against Anaxibius, but in spite of his victory was unable to prevent the conclusion of the shameful Peace of Antalcidas (387 B.C.). In 369 B.C. he was appointed to the command of the troops sent by the Athenians to the assistance of Sparta, on the invasion of Epaminondas, but allowed the Theban general to retreat from the Peloponnesus. In the Social War (357–55) he was one of the commanders of the fleet fitted out by the Athenians for the recovery of Byzantium. Being accused of treachery and neglect of duty in the battle at the Hellespont, by one of his colleagues, Chares, and put on trial, he was acquitted, while his colleague Timotheus was fined 100 talents; but though he lived to a great age, he did not again engage in active service. Iphicrates was the author of some improvements in Greek arms and accoutrements. He was accustomed always to fortify his camp in the field even in a friendly country; "Because," he said, "if, contrary to probability, I should be attacked, I may not be obliged to make the disgraceful excuse that I did not expect it." Consult the life by Cornelius Nepos and Bauer, 'Die griechischen Privat-und Kriegsaltertümer' (2d ed., Munich 1893).

IPHIGENIA, in Greek legend, a daughter of Agamemnon and Clytemnestra (according to some an illegitimate daughter of Theseus and Helen), who was to have been sacrificed to Artemis (Diana) at the advice of the prophet Calchas, when the goddess, enraged with Agamemnon, detained the Greek fleet in Aulis by a calm. Under pretense that she was to be married to Achilles, Iphigenia was led to the altar. But in the moment when the priest was about to give the death-blow Iphigenia disappeared, and in her stead a beautiful hind was substituted, whose blood gushed out on the altar. Artemis had relented, and conveyed her in a cloud to Tauris, where she became the priestess of the goddess. Conformably with the law of the country, she was obliged to sacrifice every Greek that landed there. While serving as priestess her brother Orestes came to take away the image of Artemis, as he had been advised by an oracle to do, that he might get rid of the madness to which he had been subject since the murder of his mother. Iphigenia having recognized him as her brother, the two contrived a means of escape, and carried off with them the image. The story is first told in the 'Cypria,' a Greek poem describing the events preceding the Iliad, and is depicted on vases, sarcophagi and wall paintings. The story of Iphigenia was dramatized by Euripides who composed two plays upon the subject — 'Iphigenia in Aulis' and 'Iphigenia in Tauris'; by Goethe (1789) under the title 'Iphigenie auf Tauris,' and by Racine as 'Iphigénie' (1674). It is also the subject of two operas by Gluck, 'Iphigenie en Aulide' (1774); and 'Iphigénie en Tauride' (1779). Consult Gayley, C. M., 'The Classic Myths in English Literature and Art' (2d ed., Boston 1911); Hall, F. A., 'Iphigenia in Literature' (Saint Louis 1911).

IPHIGENIA IN AULIS, opera by Christoph von Gluck, produced in Paris in 1774 and 1779, respectively, the latter being a continuation of the first. The plot is based on the Greek legend of Iphigenia, daughter of Agamemnon and Clytemnestra. To avert the wrath of the goddess Artemis (twin-sister of Apollo), whom Agamemnon had angered by killing a consecrated hind, Iphigenia was demanded as a sacrifice on the altar, pending which Artemis held the Greek fleet destined for Troy in the harbor at Aulis. Calchas, the High Priest of Artemis tells Agamemnon that a favorable wind will come only after the sacrifice. Iphigenia is prepared to immolate herself, but her lover, Achilles, forces his way through the crowd to save her, when she is miraculously conveyed in

a cloud to Tauris to become a priestess to Artemis there in the temple of the barbarous Scythians. In the second opera Iphigenia has served 15 years in performing the rites of offering human sacrifices when her brother Orestes falls into her hands, together with his friend Pylades. She does not know her brother, nor that he had slain his mother and fled, pursued by the furies. Just as she is about to stab Orestes, he declares himself, and the knife falls from her hand. Thoas, king of the Scythians, rejects her entreaties and commands that both she and her brother shall die. His design is frustrated by the return of Pylades — who had been suffered to depart — with some of his countrymen, and the king is slain. Diana intervenes with her protection and permits brother and sister to return home. The *Tauris* is by many critics considered to be Gluck's masterpiece.

IPHIGENIA IN TAURIS. Goethe's 'Iphigenie auf Tauris' (1787) was first written in prose in 1779 and was performed by members of the court of Karl August, Goethe impersonating Orestes. For the conception of the subject we therefore look to the circumstances of Goethe's life in Weimar at the end of his fourth year there. He had outgrown his «storm and stress,» he had acquired discipline and learned self-denial, and he had come to reverence in Charlotte von Stein a woman to whom he felt so spiritually akin that in a previous existence, he said, she must have been his sister or his wife. Withal, he had enough to regret of earlier misdeeds: he could fully enter into the tortured soul of the matricide Orestes. But the traditional Iphigenia was born again in his drama into the saintliness of pure and redeeming womanhood. Not unwilling to be guided by her brother, she nevertheless by her mere human presence restores him to sanity. Unwilling — as no Greek would have been — to outwit even a barbarian, she inspires a disappointed king with magnanimity and converts a nation from cruelty, merely by telling the truth. The versified form which, with little alteration of the original prose, Goethe gave to his 'Iphigenie' in Italy makes this drama an exquisite example of composition in what he himself, in a little essay written in the following year, denominated «style»: creation such as Nature would exemplify under perfect conditions, and such as art attains when, without sacrifice of individual reality, it suggests and typifies the universal. Translated by Anna Swanwick, London, 1850. Edited by L. A. Rhoades (Boston 1896).

IPIALES, ē-pya'las, Colombia, town in the Department of Cauca, on the frontier of Ecuador. It is among the highest towns of the world being situated at an elevation of 10,000 feet above sea level. It has a customs-house. Pop. about 10,000.

IPOMÆA, ĭp-ō-mē'a, a genus of plants, including several hundred species, of the family *Convolvulaceæ,* consisting mostly of twining or prostrate herbs, widely distributed in warm regions. The species of most importance is *I. purga,* which yields the jalap of commerce. Some are cultivated for the beauty of their flowers, and are known to gardeners as convolvuli. *I. purpurea,* the common morning-glory, is the best known garden species. See JALAP.

IPPOLITOV-IVANOV, ęp-pŏl'ę-tof-ę-vä'nof, **Michail Michailovitch,** Russian composer: b. Gatchina, 19 Nov. 1859. He studied at the Conservatory of Saint Petersburg under Rimsky-Korsakov, removed thereafter to Tiflis where he became director of the conservatory and the opera and also conductor of the symphony orchestra. His stay in the South resulted in the publication of a standard work on the folk-songs of Georgia entitled 'The Georgian Folk-Song.' He was made professor of composition at the Moscow Conservatory in 1893 and in 1906 was made director. In 1899 he became conductor of the Moscow private opera and did much in that capacity for the struggling composers of the new Russian school. Ippolitov-Ivanov has written the operas 'Ruth' (1887); 'Assya' (1900); 'Yabava Putyatishna' (1901); 'Treachery' (1911). Other works are 'Caucasian Sketches,' a suite for orchestra; several cantatas, a scherzo, choral works, piano compositions and some chamber music.

IPSWICH, Australia, town in Stanley County, Queensland, on the Bremer, 22 miles west of Brisbane. It is located in a thriving agricultural region, also favored with extensive coal deposits. It has iron foundries, woolen mills and lumber yards, railroad shops, etc. Pop. 14,028; with suburbs 25,000.

IPSWICH, England, a market-town, parliamentary and municipal borough and river-port in Suffolk, on the Orwell River at its confluence with the Gipping, 10 miles northwest of Harwich and 68 miles northeast of London. The older parts of the town have narrow crooked streets, some of the old houses of which are ornamented with curious carved work. It contains numerous churches and benevolent institutions, a town hall, art museum, mechanics' institute, corn exchange and an ancient mansion of the Tudors. Of its educational establishments the principal is the grammar school founded by Cardinal Wolsey and endowed by Queen Elizabeth. Ipswich is a large industrial centre, manufacturing railway supplies, agricultural implements, clothing, shoes, soap, ships, etc. About everything made of metal is turned out in Ipswich. There are municipal baths, wharves, library and markets. It sends two members to Parliament. Ipswich has some Roman remains. It was pillaged by the Danes in 991 and again in 1000. Pop. 73,932. Consult Wodderspoon, John, 'History of Ipswich' (Ipswich 1850) and 'Victoria County History: Suffolk.'

IPSWICH, ĭps'wĭch, Mass., town in Essex County, on the Ipswich River near its mouth and on the Boston and Maine Railroad, 27 miles northeast of Boston and 9 miles south of Newburyport. As Agawam, it was settled in 1633 by John Winthrop and 12 others. The name was changed to Ipswich (after Ipswich, England), in the following year, by resolution of the Massachusetts General Court. As early as 1634 it had a meeting-house, while in 1642 the first free school in the town was established. Ipswich was among the foremost towns of Massachusetts in resisting the arbitrary taxation introduced under Governor Andros in 1687 and a number of its citizens suffered punishment in consequence of this action, which foreshadowed the stand to be taken later, by this town and the colonies generally, against similar

policies on the part of the British government. The town has various industries, among the articles manufactured being grist-mill products, hosiery and underwear, bricks, lumber and boxes, carriages, cabinet-work, soap, isinglass, heels, etc. The Manning high school, the Ipswich Historical Society and the excellent public library give the town rank and influence in educational and literary affairs. Pop. 6,272.

IQUIQUE, ē-kē'kā, Chile, a seaport in the province of Tarapacá, holding the first position among all Chilean cities in the matter of exports and the third (surpassed only by Valparaiso and Talcahuano) in respect to imports. It owes its prosperity largely to the export of nitrate of soda and borax, the former of which especially is found in great quantities in the pampa of Tamarugal. In 1868 and again in 1877, the town was almost entirely destroyed by an earthquake. In 1879 it was bombarded and captured by Chile from Peru; and in 1891 it was much damaged by insurgents. Pop. in 1917 about 70,000.

IQUITOS, ē-kē'tōs, a native tribe in Peru, residing at Loreto, on the left bank of the Marañon, about 75 miles above the mouth of the Rio Napo. The settlement has an active trade, valued at $2,000,000 annually; the imports are exchanged mostly for india rubber. In 1900 they numbered about 12,000.

IQUITOS, Peru, city, river-port and capital of the department of Loreto, on the upper Amazon, near the mouth of the Nanay, 2,500 miles from Pará, Brazil. It is 350 feet above sea-level and has a healthful climate with a mean annual temperature of 75° F. There are really two towns, one of which is inhabited by the Iquitos Indians. Ocean-going vessels ascend the Amazon to this point, and the river is navigable for lesser craft for 425 miles further up. Iquitos is the second port of Peru, having three ocean lines making regular voyages thither. Its annual foreign trade amounts to $10,000,000. Rubber is the largest item of export. The city has machine shops, ship yards, hat and hammock manufactures and fish-curing. In 1908 wireless communication was installed with Puerto Bermudez; the latter place having a land line over the Andes to the capital. Iquitos was founded in 1863, but did not grow very rapidly until the Amazon was opened to navigation, since when Iquitos is the trade centre of eastern Peru. A United States consul is stationed here. Pop., municipal 6,000; district 12,000.

IRADE, ĭ-rā'dĕ, a Turkish decree or command of the Sultan, directed to his grand vizier, whose duty it is to announce it to the public.

IRAK-ARABI, or **IRAK EL ARABI,** the ancient Babylonia, now comprised in the Turkish vilayets of Bagdad and Basra. It is part of the alluvial plain in the valley of the Tigris and Euphrates. Its western part is sandy desert, and part is also swampy. Within its borders are the ruins of Babylon, Seleucia and Ctesiphon. It includes also the modern Bagdad, Basra and Kerbela. It was crossed by the British forces in 1917–18, just previous to the collapse of Turkey in the War of 1914–18. Turkish sovereignty was not fully acknowledged throughout this region and marauding bands of tribesmen frequently molest the caravans passing through. The population of the entire region is estimated at 3,000,000 probably 30 per cent too high.

IRAN, ē-răn, Asia, a general name applied to a great table-land stretching in the North from Caspian Sea, Turkestan and the foothills of the Caucasus on, from the Indus River in the East, to the Tigris River in the West, as far South as the Persian Gulf and the Indian Ocean. Politically this whole vast region is divided into Afghanistan, Persia, Baluchistan and Kafiristan and it also includes some of the border lands of British India. Persia, however, claims for itself alone, politically and otherwise, the appellation of Iran. The population forms the Iranian branch of the Aryan race. In the Pehlevi inscriptions of the famous Sassanide ruler, Shapur I (A.D. 242–72) the country is called Aïran, i.e., the land of the Aryan, in distinction from Aneran, land of the non-Aryan; the latter since the days of Firdûsi is termed Tûran.

The extremes of climate over this wide area were just as pronounced in ancient as in modern times. As witness the modern Persian saying: *Irân hêfte klimat dâred,* i.e., Iran has seven climates. Along the Persian Gulf in the districts of Busheer and Mohammerah, it is very hot, in the Elburz range intensely cold. Very diversified also have always been its characteristics and features. However, both in the remote past and in more recent times Iran, though a rather ill-defined unit, has been of enormous influence, not only geographically and ethnologically, but in its bearing on history, in the diffusion of the Indo-Germanic idioms. Topographically considered the immense area is surrounded on all sides by high mountain ranges, these aiding materially in keeping out invaders and preserving within the enclosed territory a homogeneity of language and customs. Thus, despite the numberless vicissitudes undergone by the Iranian stock during immemorial ages, all the accounts that have come down to us seem to agree in ascribing to the people of Iran a set of traditional habits and customs as well as a physical makeup which tally in the main with those still observable in the Persians of to-day.

The earlier travelers and authors, notably Eratosthenes and Strabo, limited the appellation of Ariana (or Iran, Eran) to its southeastern portion, excluding Persia proper, Media and Bactria. Pliny confounds in his description Ariana with Aria, Areia, i.e., the district of Herât. But Strabo admits that many writers gave to Ariana a more extended meaning, comprising the Persians, Medes, Bakhtrians and Sogdians, as they all spoke the same language, with slight dialectic variations.

The whole enormous area, of which the Persia of to-day with its 628,000 square miles is but about one-third, is rather poorly watered, lacks adequate rainfall in large sections of it, and presents vast stretches of salt-impregnated, wholly arid and barren land. The great desert domain of Iran, in fact, extends right across the high plateau, going from a northwesterly in a southeasterly direction, and dividing the fertile provinces of the whole into two groups. This desert is continuous from the southern base of the Elburz Mountains (overlooking in the north the Caspian) to the arid ranges of

Makrân, bordering on the Persian Gulf. It is about 800 miles in length, but varying greatly in width. The indigenous name for this desert is Dasht-i-Lût, and of it the saline swamps and the salt area are known as the Dasht-i-Kavir.

From the foregoing it may easily be seen that in productiveness, too, Iran varies enormously. It is believed to be the original home of the peach, the melon, the cucumber, the cherry and the rose, the wheat plant and the poplar. In general, on its territory grow the trees, the fruits and the cereals of the temperate and of the subtropical zones. There are districts, such as, for example, Masanderân and Ghilân, the neighborhood of Shiraz and Shuster, etc., where the yield is enormous. Wherever the rainfall is abundant, such as along the shores of the Caspian and parts of the southwest, and where woods are still remaining and rivers are flowing in a permanent bed, there is also fertility, and wherever these conditions do not subsist the contrary prevails. Some districts, like those of Busheer and Jesk in the south and around the entire shore of the Caspian Sea, have plenty of rain. Iran, however, suffers unavoidably in its prosperity from the almost total absence of large and navigable rivers.

The population of Iran — using the term in the widest sense — seems to have been much greater in antiquity than at the present time. Undoubtedly incessant warfare, deforestation and a deficient system of tilling the soil practiced for thousands of years and pursued down to our own days, as well as unwise administration and laws, are largely responsible for this.

In historical times Iran (Eran) and Fars (Persia, Farsistân) were for long periods almost identical. This refers not merely to the exploits and religion of Iran, but also to its art, science, language and literature.

IRANIAN, a name applied to racial groups of people speaking the Iranian stock of languages. In historic times the Iranians appear on the shores of the Oxus and of the rivers of upper Sogdiana, and thence spread southwest through Balkh and Badakshan. It is probable that in the flourishing ages of the Persian empire the Iranic races were spread much farther, to the Kûr and even beyond. Colonies of Iranians were to be found in the Crimea and mingled with the Thracians. It is thus established that the Iranians were in ancient times the connecting link between the Aryan races of Asia and of Europe. At an early period the Iranians and the Indians probably formed but a single group of races. In antiquity the chief components of the Iranic peoples were the Medes and Persians, as well as the inhabitants of those provinces designated as Ariana; but beside them there were also the ancient nomadic hordes of Iranic stock, the Daha or Dahans, who afterward mingled with the Turanians that occupied the steppes of Turkestan as far as the Sarmatians and Scythians of the present south of Russia. That the latter, though, were conscious of their Aryan and Iranian descent is proved by the names borne by the Scythian (Scolot) kings, such as Ariantas and Ariapeithes (Herodotus). In our day, under the head of Iranians, may be classed the Persians and the Parsis, scattered throughout Persia and India; the Tadjiks, who speak Persian and follow agriculture or commerce, in Afghanistan, Baluchistan and Turkestan; then the Koords and Lures, the Afghans, the Ossetians in the Caucasus, the Tais in the region of Baku, the Goorans in Kurdistan, the Galtchas and Pathans on the Pamir plateau and, perhaps, the Armenians. All these populations and tribes stand on very different levels of culture and are also greatly distinguished physically from each other, owing to admixture of foreign elements — such as the Uzbeks and Sarts in Central Asia, influencing the Tadjiks; the Dravidas doing the same with the Beloochees, and the Semitic neighbors in the West playing a similar part. Generally speaking, the Iranians are dolichocephalous and swart, while the Ossetians, Galtchas, etc., are brachycephalous and fair.

The system of religious worship developed by the Iranians started, of course, with that of the Aryans as a whole. With the latter they shared the myths of Ahûra, Mithras, the dragon-slayer Verethreghna (Indra), Apam — Napat (lightning); they believed in the divine afflatus brought about by *soma* and its preparation; in the injunction to "good thoughts and good works," imposed alike by the Iranian Avesta and the Indian Veda; in the supreme order of the world, controlling men and gods alike, in fire-worship, sun-worship, the sacrificial and purifying flame. And in spite of later rites, many hoary sagas and legends have survived, such as that of a fearful battle waged by the sun-god against a terrific serpent; that of the first man, Yama, who now rules in the nether world; that of the "Glorious One" (Husrava, Chosroes), who meets death at the hands of his unknown father (compare the saga of Hildebrand and Hadubrand, the Sakuntâla, the Kalevâla) and others which antedate historic times. It is certain that the Gâthas (ancient psalms) were extant as early as the 13th or 14th century before our era. Zoroastrianism, in the form in which it became the dominant creed of the Iranians, made wise use of the old gods and of the early heroes, transfusing them into efficient helpers of the All-Ruler, Ahuramazda (Ormuzd). In the reign of the legendary King Gushtasp, the patron of Zerdusht (Zoroaster), a period antedating the prevalence of his dogma in Media, in 714 B.C., by several centuries, this prophet and sole founder of one of the purest creeds of the East, attains to power as a teacher. The substance of his tenets was that in this world there are two groups of powers confronting each other in a war without cessation — the powers of Good, of Light, of Creative Strength, of Life, of Truth, and the powers of Evil, of Darkness, Destruction, Death, Deceit. The "great Wisdom," Mazda, with his servants, the "Undying Holy Ones," and a great host of subordinate angels and helpers, is forever facing, battling with, conquering the Evil Spirit (Angra Mainyu, Ahriman) and his tools. The latter are slightly

altered reincarnations of the old Iranian gods, now discarded and cursed as "Evil Workers." Zoroaster asks each man to ponder and choose his position with regard to the fundamental problems of life and religion. From his teachings sprang a priesthood, the Magians, entrusted with the task of administering to the needs of the believers. Zoroastrianism was still strong in the early part of the Christian era, and under the Sassanides, about 220 A.D., there came a revival. This we see from a polemic against the Christians (Armenians) during the reign of Yezdegerd II, about 450 A.D., the details of which have been preserved by the Armenian historian, Elishe. The creed of Zoroaster, however, toppled and fell an easy prey to Islam during the early caliphate in the 7th century. Iran, it is true, for the larger part embraced Shiah, and thus became the inveterate foe of the Sunnite Arabs and Turks; but it nevertheless became Moslem, fanatically so, and buried its ancient national faith forever. The modern Iranians have, however, retained the chief marks of their fathers — a great suppleness of mind, a joyous, lively temperament, a taste for and skill in poetry, the arts and artcraft, an extraordinary politeness and suavity of manners, coupled with rather loose morals, dislike of frankness and an enormous racial pride.

IRANIAN LANGUAGES AND LITERATURE. The dead and living languages of Iran together form, with some sporadic vernaculars existing outside its strict boundaries, the Iranian family of the Aryan or Indo-Germanic speech. Among them are, however, several that have strongly deteriorated or else show considerable mingling. Thus, Afghan is greatly intermixed with Sanskritic elements; hence it is classed with the Indic by some writers. The earliest type of Iranian we know of is the Zend or Early Bactrian, and this again shows two subdivisions, a more remote and a less remote one. Both of these we only became acquainted with from the surviving fragments of the Zendavesta, as well as from the Gâthas, a species of psalms, the latter being much the oldest of the two. The ancient tongue perished on the destruction of the Persian Empire by Alexander the Great. This ancient Zend is indubitably closely related to Sanskrit and is wholly devoid of the Semitic gutturals with which modern Persian abounds; and with its wealth of vowels (notably the flat and high "a" and "o") is both melodious and virile. Only slightly younger is Early Persian, the tongue in which cuneiform inscriptions of the Achaemenids are couched. These inscriptions, found in Persepolis, Behistun and elsewhere, which by reason of their similarity to Sanskrit and Zend, and further by reason of frequent parallel columns in Zend, are most interesting from a philological viewpoint. Early Persian and Sanskrit, have been wholly deciphered, reach down to the 4th century B.C. and show plain indications of the development of the Persian, or Iranic, idioms. Old Persian seems to have been mostly current in the west, Zend in the east of Iran. The next degree of internal change is perceived in Pehlevi, or middle Persian, for in this nearly all the former distinctive case endings and tense forms of the verb, etc., disappear. Pehlevi, nevertheless, for four centuries became the court idiom during the whole of the Sassanide dynasty. With the Arab conquest, in the latter part of the 7th century, and the enforced introduction of Islam, Pehlevi disappeared, together with the ancient faith. The remaining adherents of Zoroastrianism, the so-called Parsîs or Parsees, scattered throughout Persia or found a refuge in India. And the Parsees up to this date still utilize Zend or Pehevi for ritual purposes.

Finally, however, with Firdûsi's 'Shah Nameh,' the great national epic of Persia, the last stage, New Persian, is reached. And New Persian transcends the Pehlevi (or Middle Persian) both in its purity of idiomatic diction and in its paucity of grammatical forms. New Persian, in fine, knows no grammatical gender, no case endings whatever, and expresses the various tenses of the verb by making extensive use of auxiliaries and prepositions. It is, therefore, next to English, most deficient in grammatical forms; but to compensate for this loss it possesses a great vocabulary and a rich and nicely developed syntax. However, since the days of Firdûsi (1021 A.D.) modern Persian has again changed quite considerably, in that it has adopted innumerable words, even whole phrases, from the Arabic (losing thereby much of its one-time wealth of vowels) and in broadening its scope of word and syllable combination, such cases as a compound word made up of a noun and an adjective or of part Arabic and part Persian being by no means rare. Only the provincial dialects still spoken extensively have kept themselves freer from such wholesale borrowing, and in a sense the purest Iranic is to-day spoken in the province of Masanderan, near the Caspian. Closely related to New Persian are also the Koordish dialects, the Pashtoo (Afghan), which latter likewise prevails in the northwestern provinces of India; the Baluchi, and the idiom of the Ossetians (who call themselves Irôn, Iranians) in the Caucasus. The speech of the ancient Scythians, who dwelt on the shores of the Euxine, likewise showed Iranian type. The great hiatus between the flourishing era of Zend, during and before the Achaemenid dynasty, and the final re-establishment of a native Persian Empire under the Sassanides, was due to the rulers of foreign blood. Again, the ancient sacred literature was largely destroyed when Islam was introduced with fire and sword by the Arab invaders, although Zoroastrian worship survived to some extent in Yezd, Kermân, etc., and was also introduced in India by fugitives. The remains of the holy books extant at the time of the Arab conquest are still preserved, partly in the original language, but mostly in an ancient translation. The vehicle used in this translation was Huzvaresh, the literary form of Pehlevi. Sir William Jones (1789) was the first to identify Pehlevi as next of kin to Sanskrit, himself following in the footsteps of his French forerunner, Anguetil-

Duperron (1771). However, a whole generation passed before thorough progress was made in the reintegration of the language. Schlegel and Bopp first put Sanskrit on a sound philological basis by their extensive labors, and simultaneously the fundamental study of the allied Iranian languages also gained ground rapidly. Burnouf, Olshausen, Brockhaus, Spiegel, Haug, Lagarde, Justi, Lassen and Westergaard did much to that end. It deserves mention that our knowledge of Huzvaresh is wholly derived from the translations of the Avesta and of the Gâthas, as well as through a few other religious works, such as the Bundaheesh; furthermore, through inscriptions, coins and gems. It was not always of the same type; rather it differed considerably at different times and places, according to the larger or smaller infusion of Semitic words.

IRAPUATO, ē'ra-pwa'to, Mexico, town in the State of Guanajuato, 32 miles from Guanajuato, on the Mexican National Railway. It contains several convents and churches dating from the Spanish colonial period. The climate is very mild and certain crops are grown throughout the year. Pop. 21,000.

IRAWADI, ĭr-a-wăd'ĭ, or **IRRAWADY**, the chief river of Burma. One branch of it rises near the eastern extremity of Assam, another branch rises in East Tibet, the two branches uniting about lat. 26°. It has generally a south course, being deflected west, and its total length is over 1,200 miles. There are three rocky defiles in which its channel is suddenly contracted, the lowest near Mandalay; but from that point downward to its delta it has generally a breadth of from 1 to 4 miles. About 140 miles from the bay of Bengal which it enters by numerous mouths, the delta commences. The current of the Irawadi is generally slow—even in its upper part being no more than at the rate of two miles an hour; except during the inundations, when it flows so rapidly that no sailing vessels could navigate it but for the assistance of the southwest monsoon. It is navigable from the sea upward for steamers of five feet draft to the Chinese frontier, 900 miles from the sea. Artificial embankments extending 100 miles protect the delta lands from inundation. From Rangoon to Bhamo, crossing a bridge at Mandalay, a railroad runs parallel with the valley.

IRBIT, Russia, town in the government of Perm, on the river Irbit, 110 miles northeast of Ekaterinburg. Since 1643 an annual fair is held here which lasts throughout February and at which all kinds of merchandise and manufactures are sold. It is estimated that over 20,000 people attend and goods to the value of $20,000,000 change hands. The town was founded by the Tatars. Pop. 20,000.

IREDELL, ĭr'dĕl, **James**, American jurist: b. Lewes, Sussex, England, 5 Oct. 1750; d. Edenton, N. C., 20 Oct. 1799. He was appointed comptroller of customs at Port Roanoke, now Edenton, where he arrived in 1768, retained this office several years, and meanwhile studied law. He was admitted to the bar in 1771. He was appointed by the attorney-general his deputy in 1774, and in the same year was appointed collector of the province; in 1777 he was placed by the legislature on the bench of the Supreme Court, then just organized under the State constitution. He resigned in June 1778, and in the following year was made attorney-general of North Carolina. This appointment, too, he resigned in 1782. In 1787 he was designated by the general assembly a member of the State council and sole commissioner to collect and revise the acts of previous assemblies, which were to be considered in force in North Carolina. This collection of the laws, now referred to as "Iredell's Revisal," was published in 1791. In February 1790 he became one of the justices of the Supreme Court of the United States, and held that office till his death. He was a stanch supporter of the federal cause and worked hard for the acceptance of the new Federal constitution by North Carolina. One of the counties of his State was named after him in 1788. The 'Life and Correspondence' of Iredell was published in 1857. Consult Connor, H. G., 'James Iredell' (in *University of Pennsylvania Law Review*, Vol. LX, p. 225, Philadelphia 1912); Davis, J., 'Alfred Moore and James Iredell' (Raleigh 1899); McRee, G. J., 'Life and Correspondence of James Iredell' (2 vols., New York 1857–58).
